Sinusoidal projection is the Equatorial limiting form of the Bonne projection. The polar limiting form is a cordiform (heart-shaped) world map devised by Johannes Stabius and used widely by Johannes Werner in about 1514 and is known as the Werner projection. The Werner projection was used by Mercator and Ortelius in the late 16th century for maps of Asia and Africa. The Bonne projection has less distortion because its projection center is at the center of the region being mapped instead of at the pole.
Equidistant Conic

A conic projection with equally spaced parallels. Neither conformal nor equal area. Also known as the Simple Conic or Conic projection.

Scale

True along each meridian and along one or two chosen standard parallels, usually but not necessarily on the same side of the Equator. As a rule of thumb, these parallels can be placed at one-sixth and five-sixths of the range of latitudes, but there are more refined means of selection.

Scale is constant along any given parallel.

Distortion

Free of angular and scale distortion only along the one or two standard parallels. Distortion is constant along any given parallel. Compromise in distortion between equal-area and conformal conic projections.

Usage

The most common projection in atlases for small countries. Also used by the Soviet Union for mapping that nation.

Limitations

Use only for a single hemisphere.

Origin

Rudimentary forms developed by Claudius Ptolemy (about A.D. 100). Improvements by Johannes Ryusch in 1508, Gerardus Mercator in the late 16th century, and Nicholas de l’Isle in 1745.

Limiting Forms

Polar Azimuthal Equidistant projection: if a pole is made the single standard parallel. The cone of projection thereby becomes a plane.
Plate Carree projection: if the Equator is the single standard parallel. The cone of projection thereby becomes a cylinder.

Equirectangular (Cylindrical) projection: if the two standard parallels are symmetrically placed north and south of the Equator.

**Options**

Specify the **first standard parallel** and **second standard parallel** to tailor the projection to the area to be mapped.

Specify the **latitude origin** and **longitude origin** to center the map projection to the area to be mapped. Specifying a non-Equatorial origin causes an **oblique** projection.
Krovak Oblique Conformal Conic
An oblique variation of the Lambert Conformal Conic projection. The standard Lambert Conformal Conic projection places the axis of the projection cone coincident with the minor axis of the Earth ellipsoid. That is, the axis of the cone is normal to the Earth ellipsoid at the pole.

The Krovak projection places the axis of the cone normal to the Earth ellipsoid at some other location and so the line of the axis of the cone intersects the minor axis at some defined angle.

Scale
True only along the pseudo standard parallel.

Distortion
Free of distortion only along the pseudo standard parallel.

Usage
Used in the Czech Republic and Slovakia

Limitations
Use only for a single hemisphere centered on the given central latitude and longitude.

Origin
Created by Professor Josef Krovak of Czechoslovakia in 1922 for tax and topographic maps for the Czechoslovakian geodetic service.

Limiting Forms
The Lambert Conformal Conic projection when the axis is normal to the pole.

Options
Specify the Center Latitude and Center Longitude (normally centered on the area of interest). The Azimuth of the center line is the true azimuth of the center line passing through the center of the projection. This is also known as the "co-latitude" of the cone axis at point of intersection with the ellipsoid.

The Latitude of pseudo standard parallel is the latitude of the radius arc on the cone that is true to scale.
Lambert Conformal Conic

A conformal conic projection. Also known as the Conic Orthomorphic projection. A USGS and Manifold favorite for maps of the US. The **Lambert Conformal Conic (Single Parallel)** choice is a simplified version that uses only one parallel.

**Scale**

True along one or two chosen standard parallels, usually but not necessarily on the same side of the Equator. As a rule of thumb, these parallels can be placed at one-sixth and five-sixths of the range of latitudes, but there are more refined means of selection.

Scale is constant along any given parallel and is the same in all directions at a given point.

**Distortion**

Free of distortion only along the one or two standard parallels. Distortion is constant along any given parallel. Conformal everywhere except at the poles.

**Usage**

Extensively used in ellipsoidal form for large-scale mapping of regions of predominantly east-west extent, including topographic quadrangles (1:24,000 and 1:62,500 scale) for many of the U.S. State Plane Coordinate system zones, many maps in the International Map of the World (1:1,000,000 scale) series, the U.S. State Base Maps (1:500,000 scale), and topographic mapping in many other nations.

Also used for atlas maps of some countries. Recommended for conformal mapping of regions of predominantly east-west extent, such as the US or Russia.

**Limitations**

Normally used only for a single hemisphere.

**Origin**

Presented by Johann Heinrich Lambert (1728-1777) of Alsace in 1772.

**Limiting Forms**

...
Polar Stereographic projection: if a pole is made the single standard parallel. The cone of projection thereby becomes a plane.

Mercator projection: if the Equator is the single standard parallel or if two standard parallels are symmetrically placed north and south of the Equator. The cone of projection thereby becomes a cylinder.

**Options**

Specify the first standard parallel and second standard parallel to tailor the projection to the area to be mapped.

Specify the latitude origin and longitude origin to center the map projection to the area to be mapped. Specifying a non-Equatorial or non-polar origin causes an oblique projection.

The Lambert Conformal Conic (Single Parallel) choice is a simplified version that uses only one parallel, the central latitude. This has slightly more distortion than the full version since the cone of projection is tangent to the Earth at the one parallel.

**Example**

For maps of the United States, reasonable figures are 38 for the Center Latitude and -100 for the Center Longitude. This is a spot approximately in the center of the lower 48 states of the United States.

Use 32 for the 1st Standard Latitude and 44 for the 2nd Standard Latitude when using the full Lambert Conformal Conic version.

These are not hard and fast numbers. One may easily use 40 for the Center Latitude and 96 for the Center Longitude, which is probably closer to what most people would consider the “center” of the US. The important thing is to pick reasonable numbers that will be consistently used throughout one’s mapping, so that one’s projected maps using Lambert Conformal Conic to show the US will likely be the same. We use -100 because it is an easy number to remember, and Latitude 38 because it is the easily remembered name of a cool sailing journal on the West Coast (see www.latitude38.com).
Modified Polyconic

A pseudoconical projection that is neither conformal nor equal area. Based on the Polyconic, but differs from the ordinary Polyconic in two principal features: All meridians are straight, and there are two meridians that are made true to scale.

Scale

Meridians true to scale are 2 degrees east and west of the central meridian on sheets between latitudes 60 North and South, 4 degrees E / W between latitudes 60 and 76 N and S, and 8 degrees E / W between latitudes 76 and 84 N and S.

Distortion

Adjacent map sheets fit exactly together not only North to South but also East to West.

Usage

Used as the basis for the 1:1,000,000-scale International Map of the World (IMW) Series.

Limitations

Normally used only for a single hemisphere.

Origin

Devised by Lallemand of France and in 1909 adopted by the International Map Committee in London as the basis for the IMW. In 1962, a UN conference on the IMW adopted the Lambert Conformal Conic and Polar Stereographic projections to replace the Modified Polyconic.

Options

Specify the center longitude to center the map. The first standard latitude and second standard latitude should be approximately one fifth up from the bottom of the region covered and one fifth down from the top of the region covered. The true-scale longitude is usually the same as the center longitude.
Polyconic

A pseudoconical projection that is neither conformal nor equal area. Often called the American Polyconic in Europe. The central meridian and Equator are straight lines. All other meridians are complex curves.

Scale

True to scale along the central meridian. Each parallel is true to scale.

Distortion

Free of distortion along the central meridian and near the central meridian distortion is very small.

Usage

Used almost exclusively in slightly modified form for large-scale mapping in the United States until the 1950's.

Limitations

Normally used only for a single hemisphere.

Origin

Apparently originated about 1820 by Ferdinand Rudolph Hassler. Hassler was born in Switzerland in 1770, arrived in the US in 1850 and became the first Superintendent of the U.S. Coast Survey. Hassler died in Philadelphia in 1843 as result of exposure after a fall, trying to save his instruments in a severe wind and hail storm.

Cylindrical

Cassini
A cylindrical projection that is neither conformal nor equal-area.

Scale

True along central meridian and along lines perpendicular to central meridian. Scale is constant but not true along lines parallel to central meridian on spherical form, nearly so for ellipsoid.

Distortion

There is no distortion along the central meridian if it is maintained at true scale (the usual case).

Usage

Used for topographic mapping formerly in England and currently in a few other countries. Although the Cassini projection has been largely replaced by the Transverse Mercator, it is still in limited use outside the United States and was one of the major topographic mapping projections until the early 20th Century.

Origin

Devised by Cesar Francois Cassini de Thury (1714 - 1784) in 1745 for the survey of France. C.F. Cassini was the grandson of Jean Dominque Cassini, the famous Italian-born astronomer who changed his name from Giovanni Domenico after being hired in 1669 for astronomical research in Paris. J.D. Cassini began the survey of France and C.F. Cassini was the third of four generations involved in this project, the first detailed survey of a nation.
Cylindrical Equal Area

A cylindrical projection that is equal-area. Also known as the Lambert Cylindrical Equal Area projection. The projection upon which the even more distorting Gall projection is based.

Scale

No distortion of scale and shape at the standard parallels of the normal aspect but great distortion of shape and scale otherwise.

Distortion

Substantial shape and scale distortion near points 90 degrees from central line resulting in vertical exaggeration of Equatorial regions with compression of regions in middle latitudes and extreme vertical aspect compression in higher latitudes.

Usage

Most frequently used as a textbook example of the most easily constructed equal-area projection. Even with various proposed modifications (such as the Gall) distortions are so great that there has been little use of any of the forms for world maps by professional cartographers, many of whom have strongly criticized the intensive promotion in the non-cartographic community which has accompanied the political promotion of the re-named Gall modification (the infamous Peters projection).

Despite the shape distortion in some portions of a world map, this projection is well suited for equal-area mapping of regions which are predominantly north-south in extent, which have an oblique central line, or which lie near the Equator.

Origin

Devised by Johann Heinrich Lambert in 1772 and is the fourth of seven projections invented by him. Lambert described the transverse aspect which has very rarely been used. Even the normal aspect has been rarely used. A series of modifications were proposed by Gall in 1855, Behrmann in 1910 and others. Very similar projections were offered by Trystan Edwards of England in 1953 and a re-named copy of the Gall by Arno Peters of Germany in 1967. They were presented as revolutionary and original concepts rather than as modifications or copies of the prior projections.
Cylindrical Equidistant

A cylindrical projection that is neither equal-area nor conformal. One of the simplest of all map projections to construct and one of the oldest. Also known as the Rectangular, La Carte Parallelogrammatique, Die Rechteckige Platkarte and Equirectangular.

Scale

True to scale along the standard parallel.

Distortion

Considerable distortion away from standard parallel.

Usage

Used by USGS for index maps of the conterminous US with insets of Alaska, Hawaii and various islands on the same projection.

Origin

Probably originated with Erastosthenes (275? - 195? BC), the scientist and geographer known for his fairly accurate measure of the size of the Earth. Claudius Ptolemy credited Marinus of Tyre with the invention in AD 100.
Gall

A cylindrical projection that is equal-area. Very similar to the Cylindrical Equal Area projection (also known as the Lambert Cylindrical Equal Area projection) but with standard parallels at 45 degrees North and South.

Scale

No distortion of scale and shape at the standard parallels of the normal aspect but great distortion of shape and scale otherwise.

Distortion

Substantial shape and scale distortion near points 90 degrees from central line resulting in vertical exaggeration of Equatorial regions with compression of regions in middle latitudes and extreme vertical aspect compression in higher latitudes. Greater vertical aspect (taller) than the Cylindrical Equal Area projection upon which it is based.

Usage

Used mainly for political propaganda intended to maximize the apparent size of nations in Africa. Rarely used in professional cartography due to shape distortion. Usable for practical purposes only near the Equator.

Origin

Devised by James Gall in 1855 as a modification of the 1772 projection by Johann Heinrich Lambert.

Propaganda in Action: The "Peters Projection"

While cartographic technology, like many technologies, is of course routinely misused to lie to people for political ends, it is only on comparatively rare occasions through the centuries that political assaults have been launched against specific technologies within cartography itself. Such is the case with the "Peters projection" in modern times, when the twin hydra of political correctness and technical ignorance have combined to enmesh Gall's work within a contemporary propaganda movement. In an ironic twist, the misuse of cartography by this movement was advanced by an attack on the Mercator projection, an evil modern echo of the religious / political attack 450 years ago on Mercator himself.
Despite profound shape distortion and other defects, the Gall projection was adopted by Arno Peters of Germany in 1967, who falsely claimed the invention of the projection as his own. The "Peters projection" is, in fact, identical to the Gall except for an insignificant difference in standard parallels.

A student of political propaganda, Peters continued to claim his "invention" was distinctly different from the Gall projection even after it was conclusively demonstrated by professional cartographers that the so-called "Peters" projection was indeed the Gall. It is thus difficult to believe that Peters independently re-invented this projection as opposed to willfully plagiarizing the Gall, even if one is so credulous to think that Peters as an avid technical critic of the Mercator and other cylindrical projections could have somehow escaped noticing the vast literature describing the Lambert, the Gall and other similar projections. Like many evident plagiarists, Peters would have us believe that he managed to read the books he researched for "his" work while somehow honestly not noticing those parts he claims as his own.

Even after repudiation of their assertions by professional cartographers, both Peters and his political supporters continued to promote this "invention" through false claims. For example, the projection is claimed to be uniquely equal-area when there are numerous other projections, such as the Lambert Cylindrical Equal Area upon which it is based, that are also equal-area. It is claimed to be free of shape distortion when in fact it highly distorts shapes. It is claimed to preserve scale throughout the projection when in fact scale is true only along the two standard parallels and otherwise highly distorted throughout the projection.

Perhaps most telling of the political objectives of Arno Peters and his followers, the main claim for the projection is that it is more even-handed in presenting the true, relative size of Third World nations than are other projections, in particular the Mercator. But even this claim is false since any equal area projection will show the true areas of all nations, and numerous other projections do a better job of showing a more "realistic" apparent shape and size of different nations, including Third World nations, as they would be seen, say, to a politically-unbiased observer hovering above our planet. But then the very even-handedness of such projections works against them in service of the propaganda missions for which the "Peters" is deployed.

In fact, the Gall projection was apparently adopted by Arno Peters precisely because it distorts the apparent size of nations to overemphasize those nations favored by Arno Peters and his followers. While Peters criticized for apparent distortion the Mercator projection that is widely used for navigation worldwide, he and his followers falsely misrepresented his own use of the Gall projection as being free of distortion.

The Gall (and hence the "Peters" projection) greatly exaggerates the apparent size of equatorial countries through vertical scale exaggeration while compressing regions away from the Equator. It therefore makes First World countries in North America and Europe look smaller in comparison to Africa, which becomes enormous. This is, of course, a useful trick for political propaganda seeking to make Africa look larger and First World countries look smaller.

Note, by the way, that criticism by Peters supporters of the Mercator projection as motivated by political incorrectness is somewhat off the mark for those familiar with the technical characteristics of Mercator's projection and the history of its adoption.

As is well known to cartographers, the Mercator projection's wide adoption had nothing to do with any political agenda to minimize the geographic role of Third World countries. The Mercator won popularity first because it is easy to construct and second (and most importantly) because it shows rhumb lines as straight lines, a characteristic that is
extremely useful for navigation. The Mercator is also highly useful for conformal mapping of regions predominantly bordering the Equator, which is one reason it is often used by development and relief organizations wishing to employ effective tools in their assistance to equatorial Third World countries.

Keeping in mind that until the very recent, widespread dispersion of computers the cost of preparing virtually any cartographic presentation was very high, it made sense (especially in poorer countries) to choose a projection that works well for navigation even if the primary purpose of the map was not for navigation. If one can afford to prepare and print only one map it is prudent to create that map so it is well-suited for navigation given the likelihood that even maps prepared for other purposes might end up being pressed into service for navigation. Thus the Mercator has been widely used even in maps not primarily aimed at navigation. Indeed, many voyagers on a budget have used Mercator maps for navigation that were originally created for other purposes.

Far from promoting a thin band of First World latitudes, if anything, the Mercator grossly disfavors such latitudes by overstating the geographic importance of regions populated by Arctic peoples and high latitude indigenous populations. Perhaps what really annoys Peters advocates is that the Mercator overemphasizes the habitat of Third World populations in regions other than those favored by Peters partisans. Even so, to suggest that because the Mercator is bad one should employ the "Peters projection" doesn't hold water given the many projections other than the Mercator which are both readily available and clearly superior to the Gall should equal representation be the goal (which, of course, it is not for Peters partisans, who seek an unequal representation for their side).

From a purely technical perspective, falling for "Peters projection" propaganda does a disservice to Third World nations by applying a projection that denies them the technical benefits of more effective cartographic tools. It is a sad statement of the triumph of politically-motivated publicity that organizations such as UNESCO have adopted the "Peters projection" despite the poor cartographic properties of the projection. While some partisans apologize for the Peters movement by stating that "all maps are political," only someone bereft of technical knowledge could so claim given the many profoundly useful technical characteristics of various projections in matters that have nothing to do with politics. See, for example, the Guide to Selecting Map Projections topic.

While there will always be propagandists eager to employ GIS to deceive, all friends of GIS can fight such deception by patiently working to correct misunderstandings fostered by the popular media and other inexpert information channels. A fair representation of the Earth upon a flat surface is a noble goal, the original reason for projections to have been invented in the first place. It continues to be a goal worth fighting for even when the effort is attacked for political reasons.

Just as Mercator himself continued his work even after the attacks upon him for his own cartographic work, GIS advocates can help push back against political pressure by patiently explaining the technical properties of projections and by providing examples of how modern computer technology can show our world in a fair and neutral way for the benefit of all concerned.
Mercator

The famous conformal cylindrical projection. It is excellent for the limited purpose of marine navigation and very poor for thematic presentation. See the Transverse Mercator topic for the transverse aspect of this projection.

Scale

True along the Equator and along two chosen standard parallels equidistant from the Equator.

Increases with distance from the Equator to infinity at the poles.

Scale is constant along any given parallel; same scale at parallel of opposite sign (north +, south -) and is the same in all directions near any given point.

Distortion

Infinitesimally small circles of equal size on the globe appear as circles on the map (indicating conformality) but increase in size away from the Equator (indicating area distortion). Great distortion of area in polar regions. Conformality (and therefore local angle preservation) fails at the poles. Low distortion near the Equator.

Usage

Designed and recommended for navigational usage because of straight rhumb lines; standard for marine charts. Recommended and used for conformal mapping of regions predominantly bordering the Equator. The Mercator projection attained great fame because of its utility for marine navigation.

One unfortunate result of this fame is that it subsequently was frequently and inappropriately used as a thematic world map in atlases and for wall charts. It presents a highly misleading view of the world because of the excessive distortion of area away from the poles. The classic schoolroom map of the Earth in Mercator projection that has convinced generations of school children that Greenland is as large as North America is a case in point.

See the Gall projection topic for additional discussion of the Mercator projection, why it is especially useful in the Third World and the evil political attack on its usage.
Origin

Presented by Gerardus Mercator (1512-1594) of Flanders in 1569 on a large world map "for use in navigation".

Gerardus Mercator

A 1532 masters graduate of the University of Louvain, Mercator was originally known as Gerard de Cremere. He worked mainly in Louvain and Duisburg, where he produced most of his famous maps and was appointed Court Cosmographer to Duke Wilhelm of Cleve.

Mercator had moved to Duisburg in 1552 after the University of Louvain interceded to have him freed from prison where he had languished for seven months after being charged with heresy in 1544 after travels related to his cartographic work. He was the first to use the term atlas to refer to a collection of maps.

Mercator also invented a process for mass production of globes. In earlier times globes were produced using a labor-intensive process of engraving directly upon solid spheres. Mercator created papier-mâché, hollow globes to which he glued mass produced, hand-colored, paper engravings shaped in the now-familiar 12 gores (shapes narrowing towards the poles) plus two circular polar end caps. He produced several hundred terrestrial and celestial globes mounted in wooden stands, of which 22 matched pairs are still extant.

Over 450 years after his imprisonment, Mercator continues to be assaulted by the technologically inept but politically well-connected. See the discussion of the propaganda movement using the Gall projection in the Gall topic for the latest political assault on Mercator.

Limiting Forms

A Transverse Mercator projection is achieved when the Mercator projection's cylinder is rotated about the Earth so that instead of the Equator being the central ring of the cylinder a Meridian (that is, a longitude line) becomes the central ring.

Options

Specifying a non-Equatorial latitude origin causes an oblique projection.
Miller Cylindrical

A cylindrical projection that is neither conformal nor equal-area. A compromise between the Mercator and other cylindrical projection that attempts to eliminate some of the scale exaggeration of the Mercator. An "American version" of the Gall projection.

**Scale**

Only the Equator is true to scale.

**Distortion**

Only the Equator is free of distortion.

**Usage**

Used for world maps and in several atlases, including the National Atlas of the United States prepared by USGS in 1970.

**Origin**

Presented in 1942 by Osborn Maitland Miller of the American Geographical Society.
Modified Transverse Mercator
A USGS projection developed in 1972 for the revision of a 1954 map of Alaska. Consisting of an adaptation for the Universal Transverse Mercator projection series, it is not really a cylindrical projection but is better understood as an approximation to the Equidistant Conic projection. This projection is used for maps of Alaska and the Aleutian - Bering Sea region and is best left for experts only.
Oblique Mercator

An oblique cylindrical projection that is conformal but not equal area. The Oblique Mercator for the sphere is equivalent to a regular Mercator projection that has been altered by wrapping a cylinder around the sphere so that it touches the surface along the great circle path chosen for the central line instead of along the Earth's Equator.

Manifold provides four forms of the Oblique Mercator:

- Oblique Mercator (A)
- Oblique Mercator (A, centered)
- Oblique Mercator (B)
- Oblique Mercator (B, centered)

All four projections use the same formulae, but their initialization rules differ as noted below.

Scale

True along chosen central line, a great circle at an oblique angle or along two straight lines parallel to central line.

Distortion

Rapidly increasing distortion away from the great circle central line.

Usage

Used to map regions, such as the Alaska panhandle, that lie along oblique paths or great circles as opposed to regions that are North-South or East-West in extent. Used for grids on maps of the Alaska panhandle, for mapping in Switzerland, Madagascar and Borneo and for atlas maps of areas with greater extent in an oblique direction.

Normally, the Oblique Mercator is used only to show the region near the central line and for a relatively short portion of the central line.
Origin

Developed in 1900 - 1950 by Rosenmund, Laborde, Hotine and others.

Limiting Forms

The regular Mercator is the limiting form using the Equator as the central line, while the Transverse Mercator is the limiting form using a meridian as the central line.

Options

There are four variations of Oblique Mercator in Manifold: A and B variations as well as centered and non-centered versions. These differ from one another in how their options are used to specify the projection.

- A versions take a Center Latitude and two additional points defined by 1st and 2nd Latitude and Longitude.

- B versions take a central point defined by a Center Latitude and Center Longitude together with a Center Line Azimuth.

- Centered versions unproject 0,0 to the center of the projection, while non-centered versions unproject 0,0 to the intersection of the Equator and the Prime Meridian.

The Oblique Mercator (B, centered) version is conceptually easiest for many people. To use it, specify the Center Latitude and Center Longitude for the desired center of the map. Specify the Center Line Azimuth to be the bearing line that runs in the approximate line of the main features of the map.

For example, the illustration at the beginning of this topic was created using Oblique Mercator (B, centered) using Center Latitude 0 (the Equator), Center Longitude -90 and a Center Line Azimuth of -30. The central point defined by the Center Latitude and Center Longitude is approximately in the middle of the North American and South American landmasses near the Isthmus of Panama. An azimuth of -30 is approximately the angle made drawn through the center of masses of North and South America.

The graticule in this example was originally created in a latitude / longitude drawing for the region near North and South America. After projection into Oblique Mercator (B, centered) those portions of the graticule not reasonably near the central line of the projection were very distorted. They were selected and deleted by hand.
A conformal cylindrical projection: The transverse aspect of Mercator projection. Also known as Gauss Conformal (ellipsoidal form only), Gauss-Kruger (ellipsoidal form only) and Transverse Cylindrical Orthomorphic. Shown greatly zoomed in since profound distortion occurs outside the target region.

Limitations

The accuracy of Transverse Mercator projections quickly decreases from the central meridian. Therefore, it is strongly recommended to restrict the longitudinal extent of the projected region to +/- 10 degrees from the central meridian. [The US Army standard allows +/- 24 degrees from the central meridian].

This requirement is met within all State Plane zones that use Transverse Mercator projections.

Scale

True along the central meridian or along two straight lines on the map equidistant from and parallel to the central meridian. Scale is constant along any straight line on the map parallel to the central meridian. These lines are only approximately straight for the projection of the ellipsoid, and will be the case within Manifold when ellipsoidal Earth models (the standards) are used.

Scale increases with distance from the central meridian, and becomes infinite 90° from the central meridian.

Distortion

Infinitesimally small circles of equal size on the globe appear as circles on the map (indicating conformality) but increase in size away from the central meridian (indicating area distortion).
Usage

Many of the topographic and planimetric map quadrangles throughout the world at scales of 1:24,000 to 1:250,000. Basis for the Universal Transverse Mercator (UTM) grid and projection. Basis for the State Plane Coordinate System in U.S. States having predominantly north-south extent. Recommended for conformal mapping of regions having predominantly north-south extent.

Origin

Presented by Johann Heighrich Lambert (1728 - 1777) of Alsace in 1772. Formulas for ellipsoidal use developed by Carl Friedrich Gauss of Germany in 1822 and by L. Kruger of Germany, L.P. Lee of New Zealand, and others in the 20th Century.

Options

Specifying latitude origin and longitude origin centers the map projection.

Pseudocylindrical

Eckert IV

A pseudocylindrical, equal area projection.

Scale

True along latitudes 40°30’ North and South.

Scale is constant along any given latitude and the same for the latitude of opposite sign.

Distortion

Free of distortion only at latitudes 40°30’ North and South at the central meridian.

Usage

Thematic and other world maps in numerous atlases and textbooks and for sheet maps.

Origin
Presented by Max Eckert (1868-1938) of Germany in 1906.

**Options**

Specify the *center longitude* parameter to center the map projection.
Eckert VI

A pseudocylindrical, equal area projection.

Scale

True along latitudes 49°16' North and South.

Scale is constant along any given latitude and the same for the latitude of opposite sign.

Distortion

Free of distortion only at latitudes 49°16' North and South at the central meridian.

Usage

Origin

Presented by Max Eckert (1868-1938) of Germany in 1906.

Options

Specify the **center longitude** parameter to center the map projection.
Goode's Homolosine

An interrupted, pseudocylindrical, composite, equal area projection.

The **Clip Coordinates** checkbox **must** be checked when projecting maps into Goode's Homolosine.

**Scale**

True along every latitude between 40°44' North and South and along the central meridian within the same latitude range.

**Distortion**

Same as the Sinusoidal projection between latitudes 40°44' North and South and is the same as the Mollweide projection beyond this range. The projection is intended to be shown as an interrupted projection.

**Usage**

Whole-world maps, especially in Goode's Atlas published by Rand McNally. Because it is intended as an interrupted projection it is unsuitable for accurately showing land forms (Greenland and Antarctica) that bridge the interrupted space between the projection lobes.

**Origin**

Developed in 1923 by J. Paul Goode (1862 - 1932) of the University of Chicago as a merging of the Mollweide with the Sinusoidal.

**Options**

The illustration above shows a map window with two drawing layers. The upper layer shows countries. The lower layer contains a grid of lines created with **View - Graticule**. Horizontal graticule lines that fell in the "interrupted" zone between the projection lobes were manually selected (with **SHIFT**-select box) and then deleted. Greenland and Antarctica were selected and deleted from the upper layer.

**Tech Tip**

Interrupted projections are not continuous coordinate systems. They employ multiple conversion domains with blank space between the different lobes of the conversion domains. It is absolutely essential to check the **Clip Coordinates** box in the **Projection** dialog whenever using such projections. This box causes Manifold to clip each object so that it exists only within the allowed conversion domain lobes and does not extend or cross
through disallowed blank space. This is a highly computationally intensive process so the **Clip Coordinates** box is not checked by default, so that significant overhead is not imposed if it is unnecessary.

Dealing with the separate conversion domain lobes of an interrupted projection requires a manual approach to creating graticules, since the graticule lines normally extend through the blank space between lobes. Use the following procedure:

1. Create a latitude / longitude drawing.
2. Use the View - Graticule tool to create the desired graticule, using the option to **Create** the graticule as line objects.
3. Project the drawing into the desired interrupted projection, making sure to check **Clip Coordinates**.
4. Edit the graticule lines by selecting undesired lines and deleting them, or by adding lines.

For many uses the fastest method is to add lines. Let's consider an example of creating a graticule for use with Mollweide Interrupted. Suppose we begin with a latitude / longitude drawing in which a graticule was created with lines every 10 degrees from -180 to 180 longitude and from -70 to 70 latitude.

![Graticule Example](image)

After projection into Mollweide Interrupted with **Clip Coordinates** checked, the lines that appear on the edges of the conversion domain lobes will have been deleted.

![Projection Example](image)

We can add lines by clicking Snap To Lines and then using the Insert Line tool to add lines between the "dangling" parallels. This goes very rapidly with less than a minute required to complete the graticule.
The result will be a graticule grid with lines restored that were deleted by Clip Coordinates. This procedure was used to create the graticule seen in the interrupted projection illustration above.
**Guyou**

A conformal projection computed with elliptical integrals in the same family as the Peirce projection. Although it could be considered an azimuthal projection, it is listed here as a pseudocylindrical projection because it is often used for "horizontal" display of world regions as are cylindrical projections.

**Caution:** This is a "one-way" projection in terms of accuracy in that once data is projected into the Guyou coordinate system it cannot be re-projected to other systems without some loss of precision. The definition of the projection in common use does not include formulae for the inverse transformation, so projecting from Guyou to latitude / longitude uses iterative approximations and thus can lose precision.

**Scale**

Not true anywhere. Scale is especially false in the corners of the projection, where scale is elongated, and at the center, where scale is compressed.

**Distortion**

The projection is conformal.

**Usage**

Useful for showing equatorial regions. In its complete form (the entire Earth), may be tiled infinitely to create a display that allows any point on Earth to be viewed in a direct line from any other point.

**Limiting Forms**

The Guyou and Peirce projections are transverse cases of each other. The Guyou is the equatorial aspect (hence the classification as a pseudocylindrical projection within Manifold) and the Peirce is the polar aspect (hence the classification as an azimuthal projection within Manifold).
Options

Specify the center of the projection by setting the **center longitude**.

Origin

Presented by French mathematician Emile Guyou (1843 - 1915) in 1886.

Guyou was elected as a member of the French Academy of Sciences in 1894 and is memorialized by a street in Toulouse as well as by the Guyou Islands group and Guyou Bay in Antarctica. At the time a Captain in the French navy, Guyou prepared a report on the magnetic results of the Antarctic expedition in 1897-1899 under Gerlache as well as the 1903-1905 expedition under Charcot.
Hammer

A modified azimuthal, equal area projection. Listed here as a pseudocylindrical projection because it is often used as a pseudocylindrical projection to display the whole world at once.

**Scale**

Decreases along the central meridian and the Equator with distance from the center.

**Distortion**

Moderate. Less shearing action on the outer meridians near the poles than there is in true pseudocylindrical projections.

**Usage**

Whole-world maps, also in interrupted and condensed forms.

**Origin**

Presented by H.H. Ernst von Hammer (1858 - 1925) of Germany in 1892.

**Options**

Specify the `center longitude` parameter to center the map projection.
A pseudocylindrical, equal area projection. Also known as Homolographic projection, Homalographic projection, Babinet projection, and Elliptical projection.

The Mollweide projection is also provided in interrupted form as the Mollweide Interrupted in Manifold.

**Scale**

True along latitudes 40°44' North and South.

Scale is constant along any given latitude and the same for the latitude of opposite sign.

**Distortion**

Free of distortion only at latitudes 40°44' North and South on the central meridian. Distortion is severe near outer meridians at high latitudes.

**Usage**

Occasional world maps, especially thematic maps. Combined with Sinusoidal projection to develop other projections such as the Goode Homolosine and the Briggs.

**Origin**

Presented by Carl B. Mollweide (1774 - 1825) of Germany in 1805. Also known as the Hammer-Aitoff. Mistakenly called the Aitoff projection in the early 20th century. The Briesemeister is a modified oblique Hammer.

**Options**

Specify the *center longitude* parameter to center the map projection.
Mollweide Interrupted

A pseudocylindrical, equal area projection. Also known as Homolographic projection, Homalographic projection, Babinet projection, and Elliptical projection. The Molleweide Interrupted projection is a variation of the Mollweide projection.

The **Clip Coordinates** checkbox **must** be checked when projecting maps into Mollweide Interrupted.

**Scale**

True along latitudes 40°44' North and South.

Scale is constant along any given latitude and the same for the latitude of opposite sign.

**Distortion**

Free of distortion only at latitudes 40°44' North and South on the central meridian. Distortion is severe near outer meridians at high latitudes.

**Usage**

The Mollweide Interrupted is used to display the oceans of the world. For example, for voyagers it's a nearly perfect projection to show the path of a circumnavigation via the Panama Canal and the Red Sea.

**Origin**

Presented by Carl B. Mollweide (1774 - 1825) of Germany in 1805.

**Options**

**Clip Coordinates** must be checked.

**Tech Tip**

Interrupted projections are not continuous coordinate systems. They employ multiple conversion domains with blank space between the different lobes of the conversion domains. It is absolutely essential to check the **Clip Coordinates** box in the **Projection** dialog whenever using such projections. This box causes Manifold to clip each object so that it exists only within the allowed conversion domain lobes and does not extend or cross through disallowed blank space. This is a highly computationally intensive process so the
Clip Coordinates box is not checked by default, so that significant overhead is not imposed if it is unnecessary.

Dealing with the separate conversion domain lobes of an interrupted projection requires a manual approach to creating graticules, since the graticule lines normally extend through the blank space between lobes.

Use the following procedure:

1. Create a latitude / longitude drawing.
2. Use the View - Graticule tool to create the desired graticule, using the option to Create the graticule as line objects.
3. Project the drawing into the desired interrupted projection, making sure to check Clip Coordinates.
4. Edit the graticule lines by selecting undesired lines and deleting them, or by adding lines.

For many uses the fastest method is to add lines. Suppose we begin with a latitude / longitude drawing in which a graticule was created with lines every 10 degrees from -180 to 180 longitude and from -70 to 70 latitude.

After projection into Mollweide Interrupted with Clip Coordinates checked, the lines that appear on the edges of the conversion domain lobes will have been deleted.

We can add lines by clicking Snap To Lines and then using the Insert Line tool to add lines between the "dangling" parallels. This goes very rapidly with less than a minute required to complete the graticule.
The result will be a graticule grid with lines restored that were deleted by **Clip Coordinates**. This procedure was used to create the graticule seen in the interrupted projection illustration above.
Robinson

A Pseudocylindrical projection that preserves neither scale nor area, but which presents an aesthetically pleasing view of the entire world.

The Robinson projection is unlike most other projections in that it is not constructed by a mathematical formula used to transform coordinates systems. It is instead constructed by reference to a table of transformation parameters for meridians and parallels with an interpolation for locations between those given in the table. The table was created empirically to achieve a pleasing effect when the entire world is displayed.

Scale

Not true anywhere.

Distortion

Not free of distortion anywhere but the severe distortion near outer meridians at high latitudes seems less objectionable than in other pseudocylindrical projections.

Usage

Overview maps of the entire world intended to present thematic data and not intended to be used for distance or area measurement. The Robinson projection is often recommended as a “good compromise” projection for world thematic maps.

Origin

Created by Arthur Robinson at the request of a commercial atlas publisher in the 1960’s. Computer assisted cartography played an essential role in the trial-and-error development of the table of transformation parameters and so represents an early use of computers in the evolution of cartography. Although this is a very popular projection for world thematic maps, it is not defined either in Snyder’s famous USGS books on map projections or in Robinson’s own “Elements of Cartography.” The only technical definitions for it occur in two obscure papers: Robinson’s original announcement of it and Snyder’s publication of a small paper in a briefly published, now defunct journal reporting a computational algorithm for implementing the Robinson projection. Manifold’s Robinson projection is based on the Snyder algorithm.

Options

Specify the center longitude to center the map projection. This is normally the 0 meridian.
Special Credits

The manifold.net team would like to thank Tau Rho Alpha of the Menlo Park USGS staff for his assistance in helping us gain access to the algorithms used in the Robinson projection. A representative of our team voyaged to Menlo Park and was distressed to find the only copies of Snyder's paper were located at a different USGS facility. Mr. Alpha generously took a stranger under his wing and helped us track down the data we needed. This is but one example of a life of generous outreach to help young and old, expert and novice alike to gain greater awareness of cartography. Tau Rho Alpha has not only helped experts learn to use projections better, he is the prime mover behind an effort to help school children learn geography by creating their own globes from paper cutouts.
Sinusoidal

A Pseudocylindrical, equal area projection with equally spaced parallels. Also known as Sanson-Flamsteed and Mercator Equal-Area.

Scale

True along every parallel and along the central meridian.

Distortion

Free of distortion along the Equator and along the central meridian. Severe distortion near outer meridians at high latitudes.

Usage

Atlas maps of South America and Africa. Good for countries with great north-south extent. Occasionally used for world maps. Formerly used for other continental maps and star maps. Combined with Mollweide projection to develop other projections such as the Homolosine and the Boggs.

Origin

Developed in the 16th century. Used by J. Cossin in 1570 and by J. Hondius in Mercator atlases of the early 17th century. Often called Sanson-Flamsteed projection after later users. Oldest current pseudocylindrical projection.

Options

Specify the center longitude to center the map projection.
Van der Grinten

A curved modification of the Mercator projection that is neither equal-area nor conformal. Although it is usually classed with the various pseudocylindrical projections it is not really a pseudocylindrical projection.

Scale

Only the Equator is true to scale.

Distortion

The central meridian and Equator are straight lines. All other meridians and parallels are arcs of circles. Great distortion in polar regions. Most maps using this projection do not extend past Greenland and the outer rim of Antarctica.

Usage

Used for world maps. Used by the National Geographic Society for their standard world map until 1988, which resulted in adoption of this projection by many other groups.

Origin

Presented in 1904 by Alphons J. van der Grinten of Chicago writing in a German geographical journal and patented in the United States in 1904. Van der Grinten originally invented two projections, the first of which is known as the "Van der Grinten I" or simply the "Van der Grinten" and the second of which is (confusingly) known as the "Van der Grinten IV." See the Van der Grinten IV topic for the Manifold implementation of that second projection.

Van der Grinten's second projection is known as "IV" because after van der Grinten's original publication Alois Bludau in 1912 presented a variation of the first van der Grinten projection that became known as the "Van der Grinten II," as well as a second variation in 1912 based upon the second of van der Grinten's original projections and given the name of "Van der Grinten III."

Thus the original two projections are known as Van der Grinten I and IV, while Bludau's two variations are known as II (based upon the first original) and III (based upon the second original).

The "Van der Grinten" projection used within Manifold is the first of the series and was invented in 1898. It is the best known as the result of wide use by the National Geographic Society and the one commonly used. Van der Grinten published the projection using a
geometric construction. Manifold uses the 1979 formulae published by Snyder.

**Limiting Forms**

Used only in the spherical form.
Van der Grinten IV

A curved modification of the Mercator projection that is neither equal-area nor conformal. Although it is usually classed with the various pseudocylindrical projections it is not really a pseudocylindrical projection.

Scale

Only the Equator is true to scale.

Distortion

The central meridian and Equator are straight lines. All other meridians and parallels are arcs of circles. Great distortion in polar regions. Most maps using this projection do not extend past Greenland and the outer rim of Antarctica.

Usage

Used for world maps.

Origin

Presented in 1904 by Alphons J. van der Grinten of Chicago writing in a German geographical journal and patented in the United States in 1904. Van der Grinten originally invented two projections, the first of which is known as the "Van der Grinten I" or simply the "Van der Grinten" and the second of which is (confusingly) known as the "Van der Grinten IV." See the Van der Grinten topic for the Manifold implementation of the first projection.

Van der Grinten's second projection is known as "IV" because after van der Grinten's original publication Alois Bludau in 1912 presented a variation of the first van der Grinten projection that became known as the "Van der Grinten II," as well as a second variation in 1912 based upon the second of van der Grinten's original projections and given the name of "Van der Grinten III."

Thus the original two projections are known as Van der Grinten I and IV, while Bludau's two variations are known as II (based upon the first original) and III (based upon the second original).

Limiting Forms

Used only in the spherical form.
Projections
Wagner IV

A pseudocylindrical, equal-area projection invented by Putnins and called the Putnins P2" but almost universally known today in GIS circles as the "Wagner IV".

Scale

True along latitudes 42°59' North and South. Constant along any given latitude and the same for the latitude of opposite sign.

Distortion

Distortion is not as extreme near outer meridians at high latitudes as it is on pointed-polar pseudocylindrical projections, but there is considerable distortion throughout polar regions. Free of distortion only at latitudes 42°59' North and South at the central meridian.

Usage

Thematic world maps.

Origin

Presented in 1934 by Reinholds V. Putnins of Latvia.

An identical projection, the Wagner IV projection, was presented by Karlheinz Wagner of Germany in 1949.
Wagner VII

A modified azimuthal, equal-area projection that was the seventh in a series of new projections presented by Wagner in his cartographic work.

**Scale**

Decreases along the central meridian and the Equator with distance from the center of the projection.

**Distortion**

Considerable shape distortion in polar areas.

**Usage**

Thematic world maps, such as climatic maps prepared by the U.S. Department of Commerce.

**Origin**

Presented by Karlheinz Wagner of Germany in 1941, the Wagner VII is a modification of the Hammer projection and is also known as the Hammer-Wagner projection.
Winkel Tripel

A modified azimuthal projection that is neither conformal nor equal area. This is a low precision projection as normally used since it is calculated for a sphere and not an ellipsoid. However, when presenting whole world maps the difference between a spherical and ellipsoidal Earth is invisible.

Scale

True along the central meridian. Constant along the Equator.

Distortion

Moderate except near outer meridians in polar regions.

Usage

Whole world maps. After languishing for many years, the Winkel Tripel is becoming fashionable once more as a result of usage by the National Geographic Society.

Origin

Presented by Oswald Winkel (1873-1953) of Germany in 1921. The Winkel Tripel is obtained by averaging coordinates of Cylindrical Equidistant and the Aitoff projections. Winkel coined the name "tripel" (meaning "triple" in English) to reflect the three step process: project into Cylindrical Equidistant, project into Aitoff and then average the two projections.

Satellite View

Space Oblique Mercator

A modified cylindrical projection with the map surface defined by a satellite orbit. Basically conformal, especially in region of satellite scanning.

Scale

Continuously true to scale along ground track of satellite.

Distortion
Near-zero distortion along ground track of satellite.

Usage

Used for mapping images from Landsat series satellites. May be used for any satellite orbiting the Earth in a circular or elliptical orbit and at any inclination.

Origin

Developed in 1973 - 1979 by Alden P. Colvocoresses, John Parr Snyder and John L. Junkins. Colvocoresses was the first to realize that such a projection was needed and mathematically feasible, and in 1974 defined it geometrically. Snyder created the definitive formulas for the projection in 1977 - 1979, while less complete formulas were also created by Junkins in 1977. Snyder provided a complete derivation for orbits of any ellipticity in 1981.

Optional Forms

The Space Oblique Mercator for Landsat is a pre-computed form of the Space Oblique Mercator projection that allows specification of the projection by citing a Landsat Orbit Number and Orbit Path Number.

Historical Note

J.P. Snyder is revered throughout professional cartography as one of the giants of computational cartography. He arrived late in life to his career with USGS after a previous career as a chemical engineer. The Space Oblique Mercator projection formulae created by Snyder launched his second career in cartography.

USGS had been unable to develop projection formulae that implemented Colvocoresses's geometric definition and made an open appeal for help at the 1976 geodetic conference at Ohio State University. Snyder attended the conference while on vacation (he had a hobby interest in cartography and would schedule his vacations to allow him to attend cartographic conferences) and heard the appeal. He developed the required formulae on a pocket calculator and donated them to USGS. In 1978 he joined the professional staff of USGS and began his second career at the age of 52 as a computational cartographer.

Universal Polar Stereographic

Universal Polar Stereographic

An azimuthal projection that is conformal. A standard variation of the Stereographic projection in polar aspect that is used with Universal Transverse Mercator (UTM) projection systems to represent polar regions.

Scale

True only where the central latitude crosses the central meridian or, alternatively, along a circle concentric about the projection center (or a parallel on the polar aspect). Scale is constant along any circle having its center at the projection center, but scale increases moderately with distance from the center within a hemisphere.

Distortion
Only the center or the circle of true scale (if not the center) is free from all distortion. Areas grow greater the farther from the center, albeit in a conformal manner.

**Usage**

Employed in the UTM system to show North and South polar regions. Used from the North Pole to latitude 84 degrees North and from the South Pole to latitude 80 degrees South. In Universal Polar Stereographic projections the scale is reduced to 0.994, resulting in a standard parallel of about 81 degrees 07 minutes North or South.

**Limitations**

The Universal Polar Stereographic projection is used only from the North Pole to 84 degrees latitude North and from the South Pole to 80 degrees latitude South.

**Origin**

Apparently developed in polar aspect by Egyptians and Greeks by the 2nd Century BC. Hipparchus was apparently the first Greek to use it and is generally considered its inventor.

**Universal Transverse Mercator**

**Universal Transverse Mercator (UTM)**

The UTM system applies the Transverse Mercator projection to mapping the world, using 60 pre-defined standard zones to supply parameters. UTM zones are six degrees wide. Each zone exists in a North and South variant.

Europeans can best understand UTM by thinking of it as a world-wide version of the Gauss Kruger system, which is also based on a regular system of Transverse Mercator projections that each map a zone six degrees wide. (Americans can think of the Gauss Kruger system as a version of UTM with zones defined for European and Asian coverage.)

- **Universal Transverse Mercator**
  - The Northern Hemisphere projections for the infamous UTM system consisting of 120 zones (60 different zones with North and South variants of each). Originally developed for military use and now widely misused in civil mapping.

- **Universal Transverse Mercator (South)**
  - The Southern Hemisphere projections for UTM. These are mainly distinguished by each having a Northing parameter of 10 million so that no coordinates need involve negative numbers.

To use a UTM projection, click on the **Universal Transverse Mercator** heading in the projections categories for Northern Hemisphere regions and on the **Universal Transverse Mercator (South)** heading for Southern Hemisphere regions. Choose the UTM zone desired.

See the Projections Tutorial topic for more info on projections.

**Limitations**
The accuracy of any Transverse Mercator projection quickly decreases from the central meridian. Therefore, it is strongly recommended to restrict the longitudinal extent of the projected region when using Universal Transverse Mercator projections to ±6 degrees from the central meridian.

This requirement is met within all State Plane zones that use Transverse Mercator projections.

**Each UTM Zone is a Different Projection**

The Mercator projection maps the world onto a cylinder where the central ring of tangency is the Earth's Equator.

Near the Equator, the Mercator projection provides low distortion. Away from the Equator distortion becomes very high. This limits the utility of the Mercator projection to regions near the Equator. That is a big limitation because most places that people live (and thus, most of the regions that people most frequently map) are located not along the Equator but along North-South directions, such as from North America to South America.

Turning the Mercator projection's cylinder so that it is tangent to the Earth along a meridian (longitude line) instead of the Equator results in what is called a **Transverse Mercator** projection. If we created a Transverse Mercator projection that had a meridian as the central ring of the cylinder we could make local maps anywhere along the North-South line of tangency. If the maps are limited to the thin, vertical region near the meridian of tangency they will be relatively free of distortion.

The problem is that any Transverse Mercator projection created by choosing any one meridian as a line of tangency is useful only near that meridian. If we pick a North-South line running through Athens we can make maps all the way from Scandinavia down the length of Africa, but any maps using this projection in North and South America would be hopelessly distorted.
The **Universal Transverse Mercator** system of projections deals with this by defining 60 different standard projections, each one of which is a different Transverse Mercator projection that is slightly rotated to use a different meridian as the central line of tangency. Each different centerline defines a **UTM Zone**. The "UTM Zone" is a shorthand way of naming a specific, different projection that consists of a Transverse Mercator projection using a different meridian as the centerline. By rotating the cylinder in 60 steps (six degrees per step) UTM assures that all spots on the Earth will be within 3 degrees of the centerline of one of the 60 cylindrical projections.

To map any spot on Earth, one picks the UTM Zone centerline that is closest to it and then makes a map using that "UTM Zone" cylindrical projection.

**UTM Zones should not be Combined**

Novice UTM users usually do not realize that each UTM Zone is in fact a different projection using a different system of coordinates. New users of UTM therefore will frequently attempt to "combine" different maps created in different UTM zones into one map with the expectation that the combined map will show all objects with low distortion as did the original maps. The motivating factor is often a desire to create a map centered on a region of interest that spans several UTM zones or which is centered between two zones. Such plans fail to take into account that UTM is an intrinsically inflexible system. In effect, the UTM system assumes objects from different zones will never be seen together in the same map.

Combining objects from different UTM zones into a map that is projected using only one of those UTM zones will result in distortion in the locations and shapes of the objects that originated in a different zone map. Geographic shapes that look good in a transverse Mercator projection centered upon a given UTM zone line will be very distorted when illustrated in a UTM projection centered upon a different zone line.
The illustration above shows part of Europe projected into UTM Zone 2 in the yellow map. Overlaid on the yellow map is an Orthographic projection centered on the same map center shown in blue color. The numbers are positioned at the center of UTM Zones 1, 2 and 3.

The Orthographic map is essentially accurate over the entire illustration. In contrast, the UTM map is highly inaccurate only one half zone away from the "home" zone. Note that it distorts the coast of France so much that it has France (in the yellow, UTM projection color) crossing the Channel.

If we need to combine objects from several different UTM zones, the correct solution is to choose a different projection (such as a conic or azimuthal projection) for the combined map that provides low distortion over the entire region of interest. The illustration above shows a Lambert Conformal Conic projection in black outline and darker blue color overlaid over the Orthographic projection. Note that both projections are so close to each other it is difficult to pick out places where they differ. For example, in the region of France where the UTM projection had the continental landmass crossing the channel there is a very slight North/South offset but otherwise the two projections are virtually the same.

Remember, although no projection is perfect for all uses some projections are better than others in the uses for which they were designed. UTM was designed to map objects within one zone at a time. It is a very bad choice if objects from several zones must be shown together on the same map.
Comments

Like the State Plane Coordinate System or Gauss Kruger, UTM is a living fossil. It was created for use in expert hands as a means of dealing with the technological limitations of an earlier era. When used with skill as originally intended it still functions well within its intended uses. The problem with UTM (as with the State Plane and Gauss Kruger systems) is that it is constantly misused in civil applications by inexpert users who do not realize the limitations built into the system.
Networks

Network User's Introduction

Manifold is often used to analyze transportation networks. In this usage Manifold is very different than most other GIS or mapping products because Manifold aims at more mathematical-oriented networking analysis. Most other GIS and mapping products use bits and pieces of network math to solve highly specific tasks. This makes them good for specific tasks that are well known and accepted but less useful for extending the art.

The Manifold approach is to embed within the main system a general set of capabilities for analyzing networks using the basic building blocks of network mathematics. For specific tasks involving transportation analysis, road networks and other "traditional" GIS tasks manifold.net publishes optional add-on products in the Business Tools package.

It should be emphasized that the basic system can do everything done in the add-in products. Manifold has an unusually rich array of network analytic tools that experts can use in highly sophisticated ways to accomplish almost any network analytic task.

The mathematics of network analysis is graph theory and the same graph theoretical algorithms are used whether one analyzes paths through computer networks or paths through road networks. When Manifold was created it seemed a shame to limit such a fine analytical instrument to only analyzing some networks when it could be applied to all networks. Therefore, Manifold was built as a general tool that can be used for networks of all kinds.

This approach is not without its cultural conflicts, since GIS users who do networking analysis on transportation networks do not share the same viewpoints as computer people who analyze computer networks. Neither of these two groups shares the same culture as mathematicians who develop and extend graph theory. We have tried to resolve such social issues within the documentation by making references that are hopefully understood by all groups.
About Networks

A network consists of nodes that may or may not be connected together by links. Networks are often illustrated with dots or circles representing the nodes and straight or curved lines between nodes representing the links. Nodes may be joined by more than one link. There may even be nodes that are not connected by any link. A network drawn in a GIS or CAD system will be drawn using points for the nodes and lines for the links.

The most important thing about a network for new users to understand is that it is defined by its nodes, and not by the links. People new to network analysis will often look at a drawing of lines and think "Aha! That's a network!" However, if there are no points in that drawing there is no network in the drawing. Since GIS users will often wish to use a system of lines as a network even if it contains no nodes, Manifold takes a less strict view: default operators in Manifold will treat as a network any system of lines where the endpoints of the lines exactly coincide even if no points exist at the ends of the lines.

We could continue calling these objects "points" and "lines"; however, the terminology normally shifts into the use of the words "nodes" and "links" when a GIS map of points and lines is being treated as a network. That's because (as we will see below) there are certain implications when one says a line is a link in a network. For example, a link always runs between two nodes. There is no such thing in a network as a "line" all by itself without a point at either end.

Although networks are used to represent real systems which actually look like networks, for example, a road system, networks may also be used to analyze physical systems which don't look at all in real life like dots connected by lines. For example, networks may be used to represent the relationships between elements in complex systems such as the assembly of complex machines, scheduling tasks, or the operation of compilers.

Network theory has handy names to describe key qualities of networks, links, and nodes. Most of the time these names are quite clear and intuitively obvious. For example, a link which joins a node to itself is called a self-loop.

Links may be directed or undirected. A directed link is like a one-way street: it comes out of one node and goes into another node. Directed links are also called arcs. Networks which include directed links are called directed networks or oriented networks. Networks that have only undirected links are called undirected networks or unoriented networks. Directionality is implied in links drawing in GIS data by the sequence of coordinates that define a line.

Transportation networks involving a mix of one-way and two-way streets are often modeled as directed networks consisting of nodes joined by one or two directed links. Two-way streets are modeled as two directed links, one going each way, between nodes. However, directed links are only useful to the extent that network functions take such directionality into account. Most default Manifold network operators will ignore directionality.

Links and nodes in networks may also have weights associated with them. Weights are simply values in some data field associated with the link or node that represent some parameter that is important to the task at hand. For example, a network that represents a communications network might have a weight assigned to each link where the weight is a number giving the flow capacity of that communications link.

To take another example, consider a network that represents an interstate road system with a node for each city or major highway intersection with links between each node representing the interstate highway links between each city or intersection. Such a network might have several weights on each link representing values such as the measured physical length of that link, the maximum speed limit, the number of lanes, the average travel time over the link and so on. Nodes might have weights representing the total population in the city, average income, how many dealers we have in that city, what the average sales per dealer are, and so forth.

For the mathematically inclined...
When we talk about "networks" and "network theory" we are really discussing a branch of mathematics called graph theory. Although most people use the word "graph" in business to mean a diagram such as a bar chart, in mathematics the word "graph" refers to a mathematical object that consists of nodes that may or may not be joined by links.

In casual use, graphs are also called networks, for example as in "a road network," even though that’s not always strictly true. Since Manifold is sold mostly to non-mathematicians we use a more relaxed commercial terminology and use the term network throughout.

**Historical Note**

Leonhard Euler

Graph theory as we known it in modern times was founded by Leonhard Euler, born 15 April 1701 in Basel, Switzerland, and died 18 September 1783 in St. Petersburg, Russia. Perhaps the most prolific mathematician of all time, Euler founded graph theory while writing a discourse on the Bridges of Konigsberg problem.

The citizens of this Russian city enjoyed strolling the city while crossing the seven bridges. A popular entertainment was trying to figure out if one could walk over all seven bridges without repeating a bridge. Euler proved this was not possible.

Euler joined the St Petersburg Academy of Science in 1727 and served there until 1741 as a both a professor of physics and mathematics. He lived in Berlin for 25 years from 1741 until returning to Russia in 1766. Although almost entirely blind in the years after 1766, from then until his death in 1783 he produced almost half of his prodigious life’s product of over 880 books and papers. He was able to continue work by relying on his extraordinary memory.

**Pronunciation**

In English, "Euler" is pronounced as "oil - er" with the stress on the first syllable.
**Drawing Networks**

For most networks, usually what is most important is the relationship between the nodes and links, and not how they are drawn. That's why we can usually morph drawings of abstract networks to make them more comprehensible without losing key information. Most geographic networks should not be altered since their physical shape is often exploited to calculate values such as the length of links that we might wish to use in network analysis.

Small networks usually are easy to illustrate with simple drawings. Nodes are represented as points or small circles and links are represented as straight or curved line segments between the nodes. Directed links are supplied with arrows indicating the direction. Links in such a drawing can intersect with each other. By convention, cross points are not considered to be nodes of a network unless a node (i.e., dot or small circle) is drawn at the intersection.

Although one may illustrate a network with a drawing, note that it is the network (with its relationships between nodes and links) which is the mathematical object and not the picture drawn of it: different "pictures" may be drawn to represent the same network. For example, the following two figures illustrate the same network even though the pictures are different. Can you see why?

![Network Diagrams](image)

Not just any network can be drawn in a two-dimensional plane without the intersection of links. For example, the following illustration shows a network that cannot be drawn in two dimensions without intersections. As with the previous example, the same network has been drawn two different ways.

![Non-planar Network](image)

A network that can be drawn in two dimensions without intersections is said to be **planar**. For some problems the possibility of drawing a network on a plane without intersections is not essential; for other problems it is very important. The network illustrated is a **non-planar** network, and also happens to have the smallest number of nodes with which it is possible to draw a non-planar network.

In the "pure" mathematics of networks, as we have seen above, the same network can be drawn in different figures that except for the relationships they preserve between the nodes and links do not look at all alike. Manifold can be used in "pure" network theory to analyze networks in abstract coordinates as well as in applied network theory to analyze subjects like road networks using network concepts. In the case of computer networks sometimes the actual shape of the network is important, as in the case of a specific wiring layout for an office.
LAN, and sometimes only the abstract shape of the network is important, such as a map of links in cyberspace. At times both the physical shape and the abstract shape of a network are important.

In geographic applications we will use maps of transportation networks or other drawings where the shape of the figures is extremely important, because the shape of the figures contains important information. So, for example, in the case of a road network the shape of the roads conveys important information about their location, length, and so on. If we morph a drawing of a road network we may preserve the topological relationship between highway intersections and such but we will lose key data such as the geometric ability to calculate the length of a road by measuring the length of the link.

Let’s take for example a road system where interstate highways are links and cities or intersections between major highways are nodes. There are very many useful analyses that can be done on such a transportation network without ever having to render it as anything more than an abstract collection of lines and points. In fact, many useful analyses can be done simply from matrices listing nodes, links, and their weights without doing any rendering at all. However, even more can be done using the additional data that comes from examining the network as a real geographic map.

For example, suppose we have a real map of the network showing all the twists and turns of the road system that occur in real life but we don’t have the actual distances between each link. We can apply computational geometry to the map and compute what the distances are and then save each distance as a weight on each link. Manifold is frequently used for such tasks.

At times networks are used together with computational geometry, for example, in drawing Gabriel networks or relative neighborhood networks, where the entire essence of the resultant network derives from how it is drawn. In such cases, the precise physical way in which the network is drawn matters very much. In fact, in such networks the geometric proximity of one node to another is one of the factors used to determine if the two should be joined with a link.

When analyzing physical systems with networks it is important to strike a healthy balance between using networks that are drawn to look like the systems they model and more abstract renderings that can reveal relationships that the ordinary physical layout conceals.
Not All Maps are Networks

A typical use of Manifold System is to load an electronic map showing a road network and to then do some network analysis on the road network. Since points connected by lines are automatically treatable within Manifold as nodes and links, usually this works just fine. However, one must be careful to note that not all data sets are immediately usable as networks. Some data sets may require processing with Manifold commands to fix problems before they may be used in network analysis.

Some Background

Recall that a network is a set of nodes that may or may not be connected by links. Although single nodes unattached to any links are OK in a network, there is no such thing in network theory as a link without a node at each end, nor is it OK for one link to "connect" to another link without a node in between.

In Manifold, the elementary geometric objects are either Points, Lines, or Areas. Geometrically, Lines are really polylines. All lines, even what appear to be smoothly curved lines, are actually seen at high magnification to be made up of straight-line segments between the coordinates that define the line. Lines are simply lists x y coordinates that define the joint between the straight portions which together make up a line. A coordinate location that defines a line is not a point or treatable as a node, it is a purely internal item that is used to draw the line. Note that even if many straight portions between many coordinates are involved, the geometric Line object they define is still a single object in Manifold.

Lines are not Links without Points at Each End

Points are automatically treated as nodes and Lines between Points as links in network work within Manifold. If a Point happens to be positioned exactly at the same location as one of the end coordinates of a Line, then for network theory purposes that Point as a node is attached to the link that line represents. If the Point is positioned anywhere else other than exactly coincident with the end of a line it is an unattached node.

Note that as a matter of geometry it is perfectly possible for a Point to be drawn somewhere in the middle of a Line. However, in a network theory context, that Point would be regarded as an unattached node even though the drawing illustrated in a map window seems to show the Line running right through that Point. Remember, if a Point is not exactly at the end of a line it is not attached as a node to that link.

Lines that do not have Points at each of their ends are not links. From a network perspective, they do not exist.

It will be immediately obvious to the experienced CAD or GIS user that the above requirements for networks will encounter all sorts of problems with real life maps of lines and points that one may wish to use as networks. A typical problem is that a user gets handed a "road map" drawn in AutoCAD .dxf where all the roads are illustrated as lines. There are no points at all in the map, just a bunch of lines the ends of which may or may not be coincident when viewed at high magnification.

Since GIS users will often wish to use a system of lines as a network even if it contains no nodes, Manifold takes a less strict view: default operators in Manifold will treat as a network any system of lines where the endpoints of the lines exactly coincide even if no points exist at the ends of the lines.

Note: To add points (nodes) to the ends of all lines, use the Node Points transform operator using the Transform toolbar. It’s not a bad idea to have true networks in case user-supplied scripts or more rigorous operations insist that the map in use contain a true network.

Problems with Data Sets

There are several classes of common errors that might affect the use of a given data set as a network.

Points might not be coincident with the ends of Lines. The Point is an unattached node and as far as any network function (like routing) is concerned, the line does not exist in the network.
One Line may end at a given location and another Line might start at that location but there may be no Point at that location. The two points are not joined by a link, since the Lines between them do not exist as far as the network is concerned. Or, in a variation on this theme,

What appears to be a single Line (link) between nodes is actually made up of several Lines without nodes at their coincident ends. These nodes therefore are not joined by a link. Even though the map’s line objects abut each other, they are separate line objects. If there’s no Point at the exact ends of each of those lines they are not links and so do not exist in a network sense.

A Point may be coincident with one end of a Line, but there may be no Point at the other end. This is still an unattached node, since the "stub" line does not exist as a link.

A Line may have a Point at each end, but the next Line in what is intended to be an adjacent link may not have its end exactly coincident with the previous Line and Point. If interpreted as a network, the illustration shows a path consisting of three nodes joined by two links, plus a fourth, unattached node.

The ends of Lines intending to be incident to the same Point may not all be coincident, not with each other or with the Point. Taken as a network, this illustration shows three unattached nodes and no links.

All of the above problems often occur when software designed for freehand drawing (but which is utterly ignorant about networks) is used to create drawings intended for use as networks. The above problems can also occur when network-aware software such as Manifold is used in a sloppy fashion to draw new maps. For example, if we fail to use Snap correctly when drawing new lines it is easy to create lines the ends of which are not exactly coincident with points.

It’s easy to think that the Points in a given layer are connected by Lines when closer magnification will reveal they are not actually connected by the Lines. Perhaps the points lie near to the ends of the Lines, but they do not exactly coincide, or the Points are positioned on Lines at some middle area between the ends. It’s easy to think that just because there is a kink or sharp angle in a line that the kink marks the joint between two Lines and thus putting a Point there will attach it. However, such a kink might not mark the spot where two Lines come together, it just may be a sharp change of direccio in a single Line.

CAD drawings often have this problem, since many CAD renderings are drawn to a level of accuracy which makes lines and points “look connected” at the scales at which the drawings are normally viewed or printed. However, very frequently at high magnification the ends of the lines don’t coincide, the points are slightly detached from the lines and so on. Even a microscopic break is a gap for an automated command. One way of remediying this is to use Snap when drawing lines and points, so that the cursor snaps to exact locations.

Tech Tip:

Run the Normalize Topology transform toolbar operator to attach points and lines that are not attached within the network.

Internet Map Server

Map Server Overview

The Manifold Internet Map Server (IMS) is an integral part of all Manifold editions except Personal Edition. When Manifold System Professional Edition or above is installed on a Windows web server, that machine will acquire the ability to host IMS web sites. Manifold IMS provides the following capabilities:

- **An Internet Map Server** for GIS-enabled websites using standardized templates that allow people visiting with ordinary browsers, such as Internet Explorer (IE), to view and query maps and other components within Manifold projects.

- **A programmatic interface** to the Manifold Internet Map Server allowing creation of GIS-enabled websites that provide access to Manifold projects, such as viewing, querying and a wide variety of operations with data in Manifold projects.

- **An administration page** for administrative access to IMS through the web.

- **Creation of a Manifold Image Server** interface page, allowing remote applications and Manifold System clients to fetch image tiles on demand for served images, much as how TerraServer or other image servers provide access to images.

- **OGC WFS server** functionality to enable OGC WFS clients to interact with vector data in the Manifold project, including altering data within served components.

- **OGC WMS server** functionality providing image serving to OGC WMS clients, including to Manifold System clients fetching linked images through OGC WMS.

Note that Manifold System is both a client and a server for OGC WMS and the Manifold Image Server interface; however, although Manifold IMS can be a server for OGC WFS, Manifold does not yet provide OGC WFS client capabilities. Manifold provides OGC WFS server capabilities so that those users who are using OGC WFS clients can get data from a Manifold IMS website.

Web Requirements

This topic assumes the reader is familiar with Microsoft Internet Information Server (IIS) as well as web programming using HTML and Active Server Pages (ASP or ASP.NET). Creating web sites with IIS is a straightforward process supported by a vast array of books and other educational resources. If you are not familiar with the operation of IIS, please get a good book on the subject and learn elementary IIS operation and administration before attempting to work with Manifold IMS. The IMS topics in this documentation provide some tips on working with IIS and Windows, but they are not a replacement for reading and understanding Microsoft documentation on IIS and Windows.

It is not at all difficult to create and publish a simple web site with Microsoft IIS; however, if you are unable to do this you also will not be able to publish a web site that uses Manifold IMS: please resolve any difficulty with your IIS installation before beginning work with Manifold IMS.

Before attempting to use Manifold IMS, please take a moment to create an ordinary .HTML web site on your server and then browse it from a different machine. If you cannot do this, stop. Do not attempt to work with Manifold IMS until you can get a simple web site up and running. This step is recommended even for experts: it is amazing how often people are "sure" they can get a web site up when for some unexpected reason, perhaps a simple oversight, they cannot.

**Very Important:** By default, IIS 7 running in Windows Vista does not allow web applications to create files in the Temp folder. When using IIS 7 in Windows Vista you must allow web applications to create files in the Temp folder. See the IIS 7 and Vista Notes section below.

Manifold IMS

All editions of Manifold System except for Personal Edition include the ability to publish a map for viewing on Internet through ordinary browsers. The Manifold Internet Map Server (IMS) is an integral part of Manifold System. Manifold IMS can publish maps, drawings, images or surfaces from .map files to Internet in conjunction with Microsoft’s Internet Information Server (IIS).

In addition to providing web sites that can be viewed with a browser, Manifold can also provide three specialized types of servers:
• **Manifold Image Server** - A Manifold Image Server is a generic type of image server for which drivers can be created and installed via the Manifold Image Server Interface (ISI) to enable usage within Manifold System clients. ISI drivers have been written for TerraServer, Google Earth, Yahoo Maps and Microsoft Virtual Earth, to name a few image servers. Manifold includes a built-in ISI driver to enable Manifold clients to acquire images on demand from a Manifold IMS installation, which can function for those Manifold clients as an image server. See the **Linked Images from Manifold IMS Web Sites** topic. Manifold is both a client and a server for the Manifold Image Server interface.

• **OpenGIS Consortium (OGC) WMS Server** - An OGC WMS server synthesizes images to deliver upon request to OGC WMS clients. Manifold is both a WMS server and a WMS client. See the **Linked Images from OGC WMS Servers** topic for information on using Manifold as a WMS client.

• **OpenGIS Consortium (OGC) WFS Server** - An OGC WFS server serves vector data to clients and can accept modifications to that data from clients. Manifold can function as an OGC WFS server for vector components such as drawings, themes and maps that contain drawing or theme layers. Manifold is a WFS server but is not a WFS client.

With Manifold IMS anyone with a Windows server and a DSL connection, cable modem with static IP or other full-time Internet connection with a static IP address can publish dynamic map projects to the web for the entire world to see. Organizational users can publish Manifold projects on their Intranets to provide convenient viewing of data through browsers.

There are four steps to using Manifold IMS to publish to the Internet:

- Use Manifold to create a project containing the map or other component to be published. The entire rest of this documentation describes the many capabilities of Manifold at your disposal for creating cool maps.
- Create the files required for a map server web page using File - Export - Web Page. This topic describes this step in detail.
- Use the created files within a web site. If the files are created directly within a folder in your IIS directory tree (such as C:\inetpub\wwwroot) the result of the File - Export - Web Page dialog will be an immediately "live" web site. This step is covered in the next topic, Creating a Web Site.
- Check to make sure the **IUSR_** account for the IIS machine (or, the **NETWORK SERVICE** account or **ASPNET** account if applicable) has access permissions to the web site you have created. Use Windows Explorer to view the security settings on all files involved in your web site. [This is an elementary part of setting up a web site within IIS and is really part of the third step above; however, it is so often overlooked by novice webmasters that Technical Support asks we include this as an explicit fourth step.]

Web programmers who understand ASP or ASP.NET technology can, of course, edit the files created by Manifold in the Export Web Page dialog to make their own customizations. Experienced web programmers can write their own ASP or ASP.NET files from the ground up, instantiating and working with Manifold objects as desired to create whatever Manifold-enabled web sites are desired.

Manifold exposes a very wide range of objects enabling the creation of rich web-based applications by programmers. There are many more capabilities made possible through customized programming, for example, display of terrains, than can be captured within the default templates within the automated Export Web Page dialog. Aspiring webmasters should study carefully the examples published by Manifold in the **Free Stuff** page on the manifold.net web page for ideas.

### Installation and Activation

Manifold IMS is an integral part of Manifold System. Manifold System must be installed on the machine that runs a Manifold IMS web site.

- During installation, the installation dialogs offer a choice to install Manifold System for anyone who uses the computer or just for the login in use. Manifold System must be installed for use by everyone who uses the computer in order for Manifold IMS to function.
- When Manifold is running as a map server it will not raise the Activation dialog. Before attempting to use the map server within Manifold you must launch Manifold interactively at least once to provide a serial number for preliminary installation, or a serial number and Activation key for permanent installation. See the Activation Keys and Serial Numbers topic.
- Note: after installing Manifold on a new IIS machine for the first time, do an **iisreset** command or reboot the system.
You cannot run Manifold interactively at the same time IMS is running, and you cannot run IMS at the same time that someone is using Manifold interactively on the same machine. If you are trying to use the same machine to run Manifold interactively and also to host an IIS / IMS web site, you must organize your activities so that an interactive session and IMS are not working together at the same time (or, one or both will not work). In such cases you must do an iisreset command after working with Manifold interactively before launching IMS, and you must stop the website and then do an iisreset command before launching Manifold interactively.

You can use a Manifold Runtime license to operate an IMS website. However, using a Runtime license requires more computer literacy because the Activation and administration of a Runtime license requires more advanced skills. Almost always, any serious application will deploy Manifold IMS using a Universal Runtime license because the price differential between a Professional Runtime license and a Universal Runtime license is slight and deploying with a Universal Runtime license assures that all extensions will be available in the future. Using a Universal Runtime license also eliminates the logotype that will otherwise be embedded within Manifold IMS displays.

Using the File - Export - Web Page Dialog

To publish a map page for use with Manifold IMS, open the component to be published and choose File - Export - Web Page to launch the Export Web Page dialog. This dialog creates a set of Active Server Page (.asp) pages or ASP.NET pages that can be used in a Microsoft IIS web site.

The Manifold project must have been saved at least once to enable the File - Export - Web Page command. A new project that has never been saved cannot be exported as a web page, since a physical .map project file must exist somewhere on disk for use by the web site.

The following instructions assume we have already created the Manifold project that will be published. Most users will have a working copy of the project in some development directory. They will then save a copy of the project to a directory on the server from which it will be published. The map server can then use the copy of the project for publishing.

To create a Manifold IMS web page:

1. Launch Manifold and open the .map project that contains the component to be published.
2. Open the component that is to be published.
3. Use File - Save to save the project .map file to the location on the server where you want the working copy of the .map file to be stored.
5. In the Export Web Page dialog choose a folder in which the web page files should be created. This could a temporary folder or it could be the default folder at C:\inetPub\wwwroot that will be used for the web page. The dialog will automatically expand a dot character “.” to the name of the current folder.
6. Specify other options as desired and choose OK.
7. Close the .map file and exit Manifold.
8. Use the created files within your web site as described in Creating a Web Site.

**Dialog Options**

- **Folder**: Name of the folder in which to create the new default.asp page. Use the […] button to the right of the Folder box to call a standard Windows browse dialog.
- **Template**: Choose a template to use to create the web page. Different templates will yield different site structures as well as different appearance styles.
  - **Standard**: Allows all options. Displays each new table in a new browser window.
  - **Standard (framed)**: Allows all options. Displays tables in a frame within the same browser window.
  - **Compatible with 4.x browsers**: Allows all options except the Info tool. Generates HTML compatible with older browsers. Displays tables in the same browser window, thus requiring a back command to see the map.
again.

Template selections also include ASP .NET versions of the templates. These should only be used when operating Manifold IMS in an ASP .NET environment. See the section at the end of this topic on using Manifold IMS in ASP .NET.

**Size**

Size of image to serve. The actual visualization of maps or layers within maps must be served to the browser as an image. Choosing this parameter chooses the size of image served. Any size may be specified, although usually settings are similar to aspect ratios seen in computer display monitors to provide pleasing proportions. Typical settings might be 320x240, 400x300, 640x480 to 800x600. Larger images will result in slower map server operation and slower downloads for viewers. Larger images will also require more of your Internet connection bandwidth.

**Embed description info**

If checked, write text properties into the .png image that is served in the web page using the component name as the Title property, the component's description text property as the Description property and the Software property set to the "Manifold System..." identification string displayed in the Help - About dialog. This option is a useful way of embedding copyright slogans: enter the copyright text or whatever other text you want embedded into the image into the component's Description property and it will be embedded into the .png image served. Virtually no one who saves your web site's image to their local machine will realize that you have, in effect, "watermarked" it with embedded .png text properties.

**Title**

Optional title string to use for the generated page. By default the title is set to the name of the component.

**Subtitle**

Optional subtitle string to use in the page. This string is often used to provide directions, such as "Click on a tool to choose it and then click in the map." When using the "Compatible" template, the directions might be "Click near the edges of the map to scroll in that direction."

**Copyright**

Optional copyright string to include in fine print at the bottom of the display. Set to a default copyright string by default.

**Queries**

If any queries exist in the project, they will be listed in this pane with a checkbox in alphabetical order. Check a query's checkbox to include it in a Queries pane on the web page. See the IMS Queries topic.

**Find tool**

Generates a control pane that allows searching for a particular value in a specified field. This control is for drawings and maps that contain drawings only. Note that the Find tool will list all fields in all drawings in a map that is published, excluding the ID field and intrinsic fields. To avoid confusing users, delete all undesired fields from drawings that are published. Objects found by Find will be shown in selection color.

**Hyperlinks**

Enable hyperlinks. If a drawing contains a field named URL (which may be any text type or URL type field) double clicking on an object will launch the contents of the URL field in a browser.

**Info tool**

Generates a toolbar button providing an information tool that displays fields of a clicked object or relevant information for a clicked label or pixel. The clicked object will be shown in selection color and a table will be displayed containing its fields. The Info tool will list all fields in all drawings in a map that is published, excluding the ID field and intrinsic fields.
<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Layers</strong></td>
<td>Generates a control menu that allows turning layers on and off. This control is available for maps only.</td>
</tr>
<tr>
<td><strong>Legend</strong></td>
<td>Include a legend in the web page.</td>
</tr>
<tr>
<td><strong>Location</strong></td>
<td>Generates a status note at the bottom of the display showing the latitude and longitude of the center of the current display.</td>
</tr>
<tr>
<td><strong>Logo</strong></td>
<td>Enabled in Enterprise Edition only. Uncheck to eliminate the &quot;Powered by manifold.net&quot; notice and hyperlink at the bottom of generated images.</td>
</tr>
<tr>
<td><strong>Scale</strong></td>
<td>Generates a status note at the bottom of the display specifying current scale in 1:xxx form. This control is for projected components only.</td>
</tr>
<tr>
<td><strong>Views</strong></td>
<td>Generates a pane containing a hyperlink for each named view. Named views (saved in the Views pane for that component) will appear under the names used for them in the Views pane. Available only if the component has views saved.</td>
</tr>
<tr>
<td><strong>Launch hyperlinks in new browser window</strong></td>
<td>If checked, when a user clicks a hyperlink a new browser window will be launched to display the link. Otherwise, the link will be displayed in the same window. The value of the option is saved into the <code>hyperlinksNew</code> entry within the <code>config.txt</code> file.</td>
</tr>
<tr>
<td><strong>Refresh linked components every ... minutes</strong></td>
<td>Automatically refresh every given number of minutes any linked component, such as a linked drawing or other linked component, which is used in the published component. Refreshing a linked drawing will update it from the controlling database table and refreshing a linked table will guarantee that it uses the latest values from the external table. Choosing a value of 0 will cause the project to be refreshed on every browser request. Do <strong>not</strong> choose 0 unless a very small number of users will be visiting the website.</td>
</tr>
<tr>
<td><strong>Include admin page</strong></td>
<td>If checked, create an administrative page for the web site in the form of a <code>default_admin.asp</code> page. The administration page shows the number of current sessions, the dates of the first hit, last hit and last reload, the total hits and a <strong>Reload</strong> button that can be used to force a reload of all <code>.map</code> files used by all sites hosted by this IMS server. If you create a <code>default_admin.asp</code> page for your IMS site, <strong>make sure</strong> to change access permissions on it so that ordinary Internet browsers cannot use it.</td>
</tr>
<tr>
<td><strong>Include Manifold Image Server interface page</strong></td>
<td>Creates an <code>imageServer.asp</code> page that allows Manifold clients to fetch images from this website using the Manifold Image Server interface via linked images. See the Linked Images from Manifold IMS Web Sites topic.</td>
</tr>
<tr>
<td><strong>Include OGC WFS interface page</strong></td>
<td>Create an <code>wfs.asp</code> file that allows OGC WFS clients to use this Manifold IMS web site as an OGC WFS server. Works with all web site templates. Turning on this option turns on OGC WFS server functionality via the resultant <code>wfs.asp</code> page.</td>
</tr>
<tr>
<td><strong>Include OGC WMS interface page</strong></td>
<td>Create a <code>wms.asp</code> file that allows OGC WMS clients to use this Manifold IMS web site as an OGC WMS server, supporting a variety of WMS protocol versions. Works with all web site templates. Turning on this option turns on OGC WMS server functionality via the resultant <code>wms.asp</code> page.</td>
</tr>
<tr>
<td><strong>Use custom server capabilities document</strong></td>
<td>Enabled only if the <strong>Include OGC WMS interface page</strong> option is checked. Allows specifying a custom XML capabilities document for the <code>wms.asp</code> file to use. If we enable this option we must provide a server capabilities document.</td>
</tr>
</tbody>
</table>
document written in XML using the schema published by OGC for such documents. Note that this document is not something that is created automatically by Manifold. If desired, we must provide a capabilities document. Such documents normally include information of interest to WMS consumers, such as, perhaps, the pricing and availability of a WMS service or other information.

Save proxy connection and file locations in the config file

By default, this option is turned off, to minimize the risk of leaking sensitive data such as passwords or physical paths used on the system. In some cases, such as when the exported web page uses components linked from remote servers, it might be necessary to turn the option on to supply these components with data required for correct function. See the topic on config.txt options for details on config.txt lines written.

Note: Attempting to export a web page that contains an image linked from a remote server or a map that includes such an image as a layer will display a warning message if this option has not been checked. This is a reminder to reconsider if proxy connection info and file locations will be required in the config.txt file.

Default Controls

The following buttons are created if their control is selected in the web page dialog. Examine the image file names used in the created web page to see the names of the files. These may be opened and edited to alter the appearance of the buttons, if desired, or other graphics files may be substituted by editing the created web page.

- Zoom in - Zoom to a closer view.
- Zoom out - Zoom to a view farther away.
- Zoom Box - Zoom into the box drawn with the tool. Created only with Standard and Standard framed templates.
- Zoom to Fit - Zoom to fit entire data set in current view.
- Center - Center view at clicked location.
- Info Tool - Show data fields for object. Shows all fields in all drawings in a map that is published, excluding the ID field and intrinsic fields
- Expand Heading - Open a tool such as Find.
- Contract Heading - Close a tool such as Find.

Controls used in sites generated with the Compatible template are simpler. The map is panned by clicking at different locations in the map with the mouse cursor. Other controls are simple links. Webmasters should experiment with the map server by creating the same web site using different templates to see the different pages created.

Files Created

The Export Web Page dialog creates several main files and one directory containing additional files that are used in the web site to create the web page seen by browsers. Files are created by default in the folder specified by the Tools - Options - File Locations - Web Pages option, by default, C:\Inetpub\Wwwroot.

Files created by the Export Web Page dialog include:
default.asp  Main .asp page. Calls other pages with or without frames depending on the template used.

default.css  Cascading style sheet file specifying fonts and other styles.

default_admin.asp  Administration page that shows the number of current sessions, the dates of the first hit, last hit and last reload, the total hits and a Reload button that can be used to force a reload of all .map files used by all sites hosted by this IMS server. This administration page is created if the Admin page box is checked in the Export Web Page dialog.

If you create a default_admin.asp page for your IMS site, make sure to change access permissions on it so that ordinary Internet browsers cannot use it.

config.txt  Configuration information. Provides path to the .map file to be used, the name of the component within the .map file to be published, x size in pixels of image, y size in pixels of image, an optional title and an optional subtitle. The path to the .map file to use is taken based on whatever .map file was being used when the Export Web Page dialog was used. The config.txt allows setting some other options, such as click radius, manually.

images  A directory containing image files in .png format that are used to create toolbar buttons and controls.

imageServer.asp  An interface page that allows Manifold clients to fetch images from this website using the Manifold Image Server interface via linked images. See the Linked Images from Manifold IMS Web Sites topic.

map.asp, mapview.asp, tableview.asp  Accessory .asp files that may be created by some templates that are used to create tables and manage the map view displayed.

wfs.asp  An OGC WFS interface file to be used by WFS clients, if the OGC WFS interface page option has been enabled.

wms.asp  An OGC WMS interface file to be used by WMS clients, if the OGC WMS interface page option has been enabled.

The .asp files work in concert to generate the HTML stream that is sent to a browser by IIS to display the map image, toolbar, status bar, menu panes and tables that result from queries. Scripting code within the .asp files calls the map server to generate the correct view. Toolbar buttons and other controls are drawn using images stored in an images subdirectory.

Default Configuration

Optional templates used within the Export Web Page dialog will create different pages. The configuration seen in the browser window depends on choices made in the dialog. The illustrations shown below use the Standard template, which is designed for use with newer browsers. The Compatible with 4.x browsers template uses a simpler style. TheCompatible template provides all functions of the Standard templates except the Info button.
The default layout positions a toolbar above the main view. Buttons allowing zooming and positioning are in the toolbar.

Optional tools such as the Find tool or Legend are positioned in menu bars to the right.

Clicking on the down arrows in the menu headings expands the tools.

Permissions

Manifold documentation assumes the user is working with a modern Windows release such as Vista, Windows Server 2003 or XP using the NTFS file system.

Manifold must be installed for everyone to use on the machine.

The .map file used with the web site must have security permissions such that the IUSR_account used for Internet browsers has read access (or, the NETWORK SERVICE account or ASPNET account if applicable). This account begins with "IUSR_" and ends with the machine name. For example, if our machine is called MAPSERVER the account will be called IUSR_MAPSERVER.

Very important: In 32-bit and 64-bit versions Windows Server 2003 and in 64-bit Windows XP the account used for Internet visitors is not the IUSR_account as with earlier Windows versions. Instead, the NETWORK SERVICE account is used. When ASP.NET is employed the ASPNET account is used.

Windows Server 2003 and 64-bit Windows XP operators should understand the NETWORK SERVICE account is meant in all cases where this documentation discusses the IUSR_account.

Web pages operating in an ASP.NET environment may require different permission settings than those operating in an ASP environment. For example, the default login used by ASP.NET is ASPNET, while the default login used
by ASP is either the IUSR_ account or the NETWORK SERVICE account. When running in ASP.NET, the .map file and all other data being accessed from the ASP.NET environment must be readable by the ASPNET user account.

ASP.NET operators should understand the ASPNET account is meant in all cases where this documentation discusses the IUSR_ account.

**Very important:** Failure to pay attention to permissions and to grant the IUSR_ account (or, the NETWORK SERVICE account or ASPNET account if applicable) read permissions to the .map file being used is the number one technical support call for IMS. If you experience difficulty browsing an IMS web site, save yourself a SERVICE Very important:discusses the account names that have access to that file. If it does not, make sure you have important:discusses the permissions.

**Important:** Make sure to use Windows Explorer to check permissions (and not the IIS management applet) and make sure you have Administrator privileges so you can view and change security settings for other accounts.

**Important:** If you use Manifold in interactive mode on the server machine to alter the .map file or even to open it, make sure to use Windows Explorer to check permissions on the IUSR_ account (or, the NETWORK SERVICE account or ASPNET account if applicable). Opening the .map in Manifold may reset its permissions to something other than having the read permissions for the Internet access account. Saving a .map file with Manifold will preserve file permissions on Windows 2000 and later systems, but this is always something worth checking.

If any linked drawings or table relations referring to external databases are used in the project that is published, the IUSR_ account must have read access to the tables that control those linked drawings or relations. In some cases, such as when .mdb files are used, the IUSR_ account must have write permissions to the folder in which those files are located, since the map server process must create a lock file as is required when working with .mdb.

Take time to think through all permissions issues. The Internet access account must have permissions to get to all the data that is used in the web site. For example, suppose our IMS project uses a linked image. Because linked images use data from the Data Cache folder (the default), we must also be sure to give the IUSR_ account (or, the NETWORK SERVICE account or ASPNET account if applicable) read permissions to access all files in that folder.

Windows administration errors that result in the IUSR_ login (or, the NETWORK SERVICE account or ASPNET account if applicable) not having read access to the .map file are one of the most frequent reasons why an IMS web site will not launch. If the IMS web site does not launch, use Windows Explorer to check the permissions on the .map file and on the folder in which it is located as well as on all other files and folders if they are involved, such as by use of a linked drawing or table relation. See the discussion in the Creating a Web Site topic for more information.

Please read the above Permissions paragraphs before contacting Tech Support with questions about IMS pages not working. Don't waste developer support incidents on easy stuff like this!

Geocoding SQL extensions will not work with Manifold IMS unless the US streets geocoding database is installed within the Manifold application installation folder (normally, C:\Program Files\Manifold System). Therefore, the US streets geocoding database should be installed in the Manifold application installation folder on machines on which Manifold IMS operates. The default installation path for the Manifold Geocoding Data product is C:\Program Files\Manifold System\GCDB, which satisfies the above criteria if Manifold has also been installed to the default path.

**Note:** Security permissions are part of modern Windows editions such as Windows 2003, Windows 2000 and Windows XP. However, security options are available within Windows 2000 only if the disk drive is formatted using NTFS. If a disk drive has been formatted using FAT32 (as is possible, for example, if someone has arranged a dual boot system that can be booted either as Windows 98 or Windows 2000) then security permissions will not be available.

Since FAT32 does not provide any security options all files and folders located on FAT32 volumes can be read by and written to by anyone (including IUSR_). This, of course, makes it entirely possible to host IIS and IMS on a FAT32 drive, albeit without any security options.

**IIS 7 and Vista Notes**
By default, IIS 7 running in Windows Vista does not allow web applications to create files in the Temp folder. When using IIS 7 in Windows Vista you must allow web applications to create files in the Temp folder. The easiest way to do this is to run the following commands from the Command Prompt with Administrator privileges as follows:

To allow web applications in IIS 7 and Vista to create files in the Temp folder:

1. Click on the Windows Start button and then use the Start Search box.
2. Enter "command" to begin searching for the Command Prompt program. A list of matches will appear.
3. Right click onto the Command Prompt program and choose Run as Administrator. Enter the Administrator password.
4. This launches the Command Prompt window with Administrator privileges. Enter the following two command lines, pressing Enter after each line (enter each line as a single line):

   icacls %windir%\serviceprofiles\networkservice\AppData\Local\Temp /grant Users:(CI)(S,WD,AD,X)
   icacls %windir%\serviceprofiles\networkservice\AppData\Local\Temp /grant "CREATOR OWNER":(OI)(CI)(IO)(F)

5. Restart IIS using IISRESET and then close the Command Prompt window.

MapPoint and IMS

MapPoint geocoding will normally not work from IMS unless we map anonymous Internet connections to a user account that has more enhanced permissions than the default Internet access IUSR_xxx account (or, the NETWORK SERVICE account in Windows Server 2003).

To enhance permissions for the Internet access account:

1. Create a regular user account with default permissions that is a member of the Users group.
2. Open Control Panel - Administrative Tools - Internet Information Services (or the equivalent dialog in your version of Windows).
3. Right click the folder that contains the published website, select Properties, switch to Directory Security and click Edit under Anonymous access and authentication control.
4. Set the user account used for anonymous access to the account created in step 1 above.

See the Geocoding with MapPoint topic for use of MapPoint as an auxiliary geocoder.

How the Map Server Operates

The files created by File - Export - Web Page are placed in a directory within the IIS web site hierarchy, and an IIS application is created using that directory (see Creating a Web Site for details). On the first call to the map server, the map server reads the config.txt file to see what .map file is to be used, the component within the .map file to be published, the size of the map to generate and text to use for tile, subtitle and copyright lines.

When a user browses into the default.asp page, IIS executes the code in the default.asp page (which invokes the other .asp files) to create a web page that is served to the user's browser. Part of the code in the .asp files involves relatively simple HTML that is easily modified. For example, the table structures used to provide the title string or the copyright string are implemented using elementary HTML that may be modified to customize the appearance of the page as desired. Other parts of the code are more sophisticated, client-side or server-side scripting commands that manage the programmatic task of detecting and reacting to user commands and updating the display.

The actual image displaying the map is created by Manifold IMS in a call to the map server. Manifold IMS opens the .map file and works with the component specified to generate a view of the component fitting the zoom and pan commands issued by the user. The map server reads the config.txt file in the same folder as the default.asp file to know how to configure the display. The final view is rendered as a .png image (or other image format as settable in the IMS config.txt file options) and served by the map server to the browser within the stream of HTML commands created by IIS's processing of the .asp pages.
From the above description it should be clear that when we use File - Export - Web Page to create a default.asp file and attendant files we are not really exporting the component into a different form. Instead, we are creating a set of instructions that are executed by IIS to call Manifold through the map server to use the published component to create web views of our data. Note that when the map server is operating the .map file is in use and cannot be opened by Manifold.

To allow simultaneous editing of the .map file, make a copy of the map file and save the copy as the .map file that is published. See Creating a Web Site for additional operational tips.

When IMS operates updating the .map file (say, by copying a different version into the same location) will not update what is served to the web. To change the .map file dynamically the .map file must be reloaded into the MapServer object either using the Reload method programmatically or by using the administrative page to force a reload manually by pressing the Reload button. Reloading will cause a reload of all .map files used on the server hosting IMS.

For expert usage, IMS opens .map files for both reading and writing. This allows doing sophisticated analysis that involves creating temporary components, such as running queries the text of which is supplied by the user.

**Operation as a WFS Server**

The Manifold OGC WFS interface can be used with vector components, such as drawings, themes and maps that contain drawing or theme layers. The Manifold OGC WFS server supports HTTP POST as well as altering data within served component or other components.

**Operation as a WMS Server**

When an OGC WMS client connects to the wms.asp page created when the Include OGC WMS interface page option is selected, Manifold serves the image tiles requested by the client. Just as Manifold in regular IMS operation provides an image that is a view of whatever map layers are being displayed, the WMS server provides an image to the specifications requested by the client of whatever layers are the map and requested by the client. The Manifold OGC WMS server respects any transparent pixels in images used, rendering the resultant images with transparent pixels as well.

Suppose, for example, we create a map that shows member countries of the European Union. We export it to a folder called C:InetPub\wwwroot\euro and we also check the Include OGC WMS interface page option. Suppose our Windows server is set up to serve the domain name mydomain.com. A visitor browsing to http://www.mydomain.com/euro or http://www.mydomain.com/euro/default.asp with their web browser would get the IMS version of the site for their browser. A visitor connecting with an OGC WMS client (such as Manifold) would use a URL of http://www.mydomain.com/euro/wms.asp to connect to Manifold running as a WMS server.

See the Linked Images from OGC WMS Servers topic for a discussion of WMS clients operation.

**Enterprise Edition and OGC WMS Server Applications**

Enterprise Edition is strongly recommended for OGC WMS server applications because Enterprise Edition allows suppression of the "Powered by manifold.net" logo that is added to all IMS images by Professional and Professional Runtime editions. Each tile transmitted to a WMS client will include the logo at the bottom of the tile. When using Enterprise Edition we can turn off the logo. Note that deploying a Manifold IMS application using a Universal Runtime license in effect installs Enterprise Edition on the server.

**Projections and OGC WMS**

There is no standard way for an OGC WMS server to describe the coordinate systems (projections) it supports that covers all coordinate systems supported by Manifold. There are several semi-standard ways using schemas to describe the coordinate system used by a WMS server that cover various subsets of coordinate systems.

When used as an OGC WMS client, Manifold supports all schemas for describing coordinate systems that have been uncovered by manifold.net, no matter how many or how few OGC WMS servers that currently exist actually use them. Given the tendency of OGC to come up with new "standards" that are never used to any significant degree, it is always possible yet another schema may be introduced in the future that is not recognized by Manifold.
as an OGC WMS client; however, we feel confident that the current edition of Manifold when used as an OGC WMS client covers all such schemas either proposed or in actual use.

In contrast, when used as an OGC WMS server, Manifold only supports EPSG codes. EPSG is arguably both the richest and the most widely used schema within the OGC community. Manifold running as a WMS server only supports EPSG mostly to avoid confusing various non-Manifold WMS clients, some of which, unlike Manifold, cannot auto-adapt to a variety of coordinate system encoding schemas.

As rich as it is, the EPSG schema only supports a fraction of the coordinate systems that can be used in Manifold. If the coordinate system used by the component served by Manifold can not be expressed using the EPSG schema, that is, if it does not have an equivalent EPSG code, then the Manifold OGC WMS server reports the coordinate system as latitude / longitude and will re-project the data for that component on the fly into Latitude / Longitude. For large components that will have a terrible impact on performance.

Obviously, it is essential that any webmaster setting up a Manifold application as an OGC WMS server should check the projections used by the components being served and should make sure that they are coordinate systems that can be expressed using the EPSG schema.

The current list of coordinate systems which have EPSG codes may be obtained free of charge from the following link, clicking the link to the epsg-v69.zip or subsequently published file:

http://www.epsg.org/CurrentDB.html

If all we are doing is using Manifold as an OGC WMS client we don’t need to worry about the above because any schema used by the OGC WMS server we access as an image server will be recognized by Manifold.

Operation as an Image Server

Manifold System can connect to image servers of various kinds (such as TerraServer or Google) to automatically fetch images that cover a desired region to create a linked image. Manifold can also function as a Manifold Image Server so that Manifold users can fetch linked images from that server using the Manifold Image Server interface built into Manifold.

When a Manifold System client connects to the imageServer.asp page created when the Include Manifold Image Server interface page option is selected, Manifold serves the image tiles requested by the client. Just as Manifold in regular IMS operation provides an image that is a view of whatever map layers are being displayed, the Image Server page provides an image to the specifications requested by the client for the region of interest.

See the Linked Images from Manifold IMS Web Sites topic.

The Administration Page

If desired, the Export Web Page dialog can create an administrative page if the Admin page box is checked.

The administrative page is a default_admin.asp page that is created in the same folder as the rest of the IMS web page. The administration page shows the number of current sessions, the dates of the first hit, last hit and last reload, the total hits and also provides a Reload button that can be used to force a reload of all .map files used by all sites hosted by this IMS server.

The administrative page makes it easy to update a .map file with a newer version without having to restart IIS. To do this, edit a copy of the .map file and save it under a similar name, making sure that after it has been saved permissions are as required. For example, if we are using myfile.map with the map server we could edit a copy and save it under the name myfile2.map. Next, change the config.txt file to use myfile2.map instead of myfile.map and then navigate to the administrative page and press the Reload button.

Because the administrative page's .asp file will be created in the same folder as the default.asp page that powers the site, it will also by default be created with the same access permissions as the default.asp page. That is, anyone going to http://(sitename)/default_admin.asp will be able to operate the administrative page. They will be able to see your web page's statistics and, more importantly, they will be able to force IMS to reload all .map files used by all IMS pages on that server by simply pressing the Reload button. Since a reload takes time, it is not a good idea to allow any visitor to force a reload however often they want to push the Reload button.
**Very Important:** If you create a `default_admin.asp` page for your IMS site, make sure to change access permissions on it so that ordinary Internet browsers cannot use it. To do this, in Windows Explorer right click on the `default_admin.asp` file, choose Properties and choose the Security tab. Remove all entries for allowed user names except Administrator or whatever other login name you wish to allow access to the administration page. Apply the settings and press OK.

Neglecting this important step will not create a security breach in that hackers will be able to steal your data, but it will allow a malevolent user to effectively shut down your map server by repeatedly causing it to `Reload.map` files.

### Layers

When a map component is published via the map server, the Layers control menu option is enabled. Choosing the Layers option in the Export Web Page dialog will add a Layers menu to the web page.

![Layers](image)

Users can check or uncheck the layers they wish to appear in the map window and then press Apply.

Layers will appear using the same names they have in the map. Therefore, one should choose wisely the names of such layers. Rename any drawings or other components so their names will be useful to people browsing the web site. For example, if creating a map of Mexico one may import a drawing of Mexican railroads from a file called `me_railroads.mfd`. This will be imported into Manifold using the name `Me_railroads Drawing`. It would wise to rename such a drawing to "Railroads" so that when it appears as a layer in the map and thus in the Layers control in the web page it is also named "Railroads".

When a map is published using Export Web Page the map server shows all layers that are in the map in the Layers pane.

### Layer Restrictions

Layer restrictions in maps are respected in that both hyperlinks and the Info tool in default web page templates will work only on layers that are clickable. To disable hyperlinks or the Info tool in a layer, open the map, right click onto that layer's tab and choose Restrictions and uncheck the clickable box. Interactive selection and editing layer restrictions are not factors in IMS web pages so these layer restrictions are ignored. See the layers pane topic for more information on layer restrictions.

Use of the clickable layer restriction is very important when creating a web page in which hyperlinks or the Info tool will be used. With such web pages there is usually a layer that contains the objects of interest while other layers serve as background layers only. The classic example is a web page that shows dealers that are near some location. The user would like to double click on a dealer point icon to launch a web page with information about that dealer, and the designer of the product wants to make sure that an accidental click on a background map layer, such as a state or nearby road, is ignored.

Accomplish this by having the layer containing the dealer points be clickable with the other layers not being clickable.

### Click Accuracy

The default click accuracy in Manifold web pages is 4 pixels. Clicking within four pixels of the center of a point will be the same as clicking directly onto the center of the point. This is normally a good balance between not requiring too much manual dexterity of the user while allowing points to be reasonably close together but separately clickable in dense displays.
To decrease click tolerance, add a line such as the one below to the config.txt file:

```
clickAccuracy = 8
```

The above line increases the clicking tolerance to 8 pixels, so that a mouse click within eight pixels of the center of a point will be the same as clicking directly onto that point.

**Control Layers with Zoom Ranges**

Many Manifold IMS pages will not use the Layers control but will publish all layers in a map as a single image into which users can zoom. In such cases we will often want layers to appear and disappear automatically as users zoom in to or out of the map. For example, as users zoom into a map we might want major roads to appear and as they zoom further into the map we would like detailed streets to appear. Control the appearance of layers using Zoom Ranges.

**Automatic Panning and Zooming**

When objects are selected with the Find tool or by a query (if the query includes the ID field), Manifold IMS will automatically pan the display to the centroid of the selected set of objects. Zoom will be adjusted to zoom to fit to the selection.

If only one object is selected and it is a point, or if several points are selected that are coincident, Manifold IMS will center the point on screen and will adjust zoom so that the display shows approximately 1/100th of the total data set. The result is usually a good level of zoom for displaying a single point within an entire data set.

**Customization**

See Creating a Web Site for notes on customizing the configuration created by File - Export - Web Page. See the Manifold web site for examples of customized IMS applications programmed in ASP or ASP .NET.

**Manifold IMS and ASP .NET**

This is an advanced subject for those webmasters who will be operating Manifold IMS in a Microsoft ASP .NET environment. To run Manifold IMS in ASP .NET we must choose an ASP .NET version of the templates in the Export Web Page dialog. You must have ASP .NET enabled in your IIS installation (easily done using IIS Manager) if you want to use ASP .NET.

The Export Web Page dialog includes ASP.NET versions of the Standard, Standard framed and Compatible templates. These must be used when operating in an ASP .NET environment.

**Automatic Refresh**

If a published component is a linked component (such as a linked drawing or other linked component) or if a map is published that includes any linked components as layers, we can turn on the Refresh linked components every ... minutes option and specify a reasonable number of minutes between refreshes. This will assure that the linked components displayed on the web site will be updated on a reasonably recent basis from the data sources from which they are linked.

Refreshes using this option apply only to that component published on the web site. For example, if the web site shows a linked drawing, this option will only refresh that drawing. If the web site shows a map incorporating as layers three linked drawings and one linked image but the project file in use also includes seven more linked drawings which are not used in the map, this option will refresh only the three drawings and the one linked image that participate in the map.

Automatic refreshes apply only to components in use in order to maximize performance, as there is normally no point to wasting machine time to refresh components that are not displayed. If for some reason we would like to refresh a particular linked component within the project other than those used in the web site, we can do this programmatically using Component.Refresh. If we want to refresh all linked components in the project file, we can easily do this using Document.RefreshAllLinked. These tasks are accomplished programmatically since it is presumed that anyone with the technical expertise to desire such customization also will have the technical wherewithal to be able to edit or write ASP or ASP .NET code.
The performance cost of refreshes varies widely depending upon the nature of the linked components and the nature of the data source providing data to the linked component. Manifold has immense flexibility and many options for creating linked components, which can get their data from many different sources.

A linked drawing, to name just a few examples from many possible, could be linked from a local table in the project, from a query or from an external data source. The external data source could be something as simple as a .csv text file or it could be something as sophisticated and powerful as an Oracle Spatial server. The communications path between the linked component could also vary. It might be as simple as a component within the same project file in the same server, or it could be a relatively slow connection via Internet to some server sitting half-way around the planet.

The data involved might be a small amount of data or a very large amount of data. Some technologies that might be used for linked components do better at providing changes (if any) when large amounts of data are involved while other technologies can be very inefficient, requiring a complete transmission of all data just to be sure any changes are incorporated.

None of these factors will surprise the experienced web developer, who is used to the notion that linking content into web pages from a variety of disparate sources and technologies exposes one to the vagaries of performance attendant to such varied sources. But the newbie web developer should think carefully about the architecture in play and not promiscuously jump to refresh frequently in a "just in case" manner to cover up any lack of understanding of how the project is put together.

It is also important not to be lured into false promises of accuracy or timeliness by refreshing a web site more frequently than makes sense given the nature of the data and the architecture of the application. For example, consider a web site that shows the positions of ocean buoys reporting weather data. The key component is a drawing linked from a geocoded table resident on some NOAA server. The geocoded table on the NOAA server is updated using some unknown software that acquires the locations of the buoys as reported by GPS devices and puts them into the table.

It doesn't make sense to refresh such a linked drawing every minute. Buoys drift very slowly to begin with, the GPS devices are not particularly accurate and ultimately it really doesn't matter for large scale weather observations over thousands of miles of ocean to know the location of a particular buoy give or take a kilometer or so. For that matter, we probably don't know how often the NOAA table is updated. Given these factors it could well be that some webmasters would choose to refresh their linked drawing every 60 minutes or so, while some more "gung ho" operators might choose a shorter interval, such as every 10 or 20 minutes.

It's true that if we don't have very many buoys (quite likely, only a few dozen and not tens of thousands) the cost of a refresh will likely be so low that it will be unnoticed even if done every minute. However, we should keep in mind that the data connection to the NOAA server might be slow even if only a small amount of data is exchanged. Therefore, it is better to think through the situation and choose a sensible refresh interval than to simply give up on thought and choose one minute "just in case."

Suppose our application works with more rapidly moving objects, such as a web site that reports the locations of vehicles, where waiting ten or twenty minutes between refreshes would give significantly inaccurate results? There are two strategies to follow in this case.

First, some vehicle tracking applications are intrinsically low resolution. Not all vehicle tracking applications provide reasonably real-time data into a database table that can also be accessed in real time. Other applications, such as the location of trucks in long-haul trucking services spanning an entire state or an entire continent, really don't care about the location of a truck give or take one or two kilometers. In such cases, we simply set the refresh interval to one minute and let it go at that. This is a good solution in such cases because such applications tend to have many more units being tracked. We usually don't need to track thousands of trucks in a small region, where it might matter how far the truck moves in one minute. Instead, we usually have to track thousands of vehicles only on a very large scale, such as over an entire state, where the precise position give or take a mile doesn't matter.

Second, for those higher resolution applications requiring faster response we can always use Component.Refresh programatically to refresh as fast as we would like. However, here too it pays to use common sense: if there is a latency lag in the entire communications chain of plus or minus ten or twenty seconds between the movement of a vehicle and the ultimate availability of that changed position to the server running Manifold, then it doesn't make sense to refresh every second. In any case we will be looking at the approximate position of a vehicle and not some exact position accurate to one meter.

Manifold deliberately uses minutes as the unit of measure in the automated refresh setting to force web developers to explicitly think about their web site's implementation and to avoid the tendency of newbies to
inappropriately pick the shortest refresh interval possible. A time scale measured in minutes is fine for lower resolution or large scale applications. Applications that need a refresh in seconds require greater professional attention which tends to come automatically with the enhanced technical skill required to use Component.Refresh programmatically.

Other HTTP Servers

Although Manifold IMS is aimed at use in a Microsoft IIS environment, one can write web pages to use IMS under any HTTP server provided the execution environment can instantiate and work with COM objects. The default templates for IMS create .asp files that are intended to be used within a Microsoft IIS environment; however, nothing prevents a user from adapting these files or writing their own script files or web pages for use with an HTTP server other than Microsoft’s IIS. This assumes, of course, that the non-IIS HTTP server being used is running on a Windows system since Manifold System runs only under Windows operating systems.

Map Server FAQ

What is the licensing for the map server? Each machine running IIS and serving from the map server must have a Manifold System license installed. Only one Manifold license is required per machine even if multiple sites are served from that machine. Any Manifold license except Personal Edition (which does not include Manifold IMS) is OK. Most users will develop Manifold IMS applications using a full license and then deploy using a runtime license, usually a Universal Runtime license.

How about generated images? That depends upon the licensing structure of the data you are using. Manifold's license permits you to serve unlimited images of any kind created from the Manifold data sets you use for no additional charge. With public domain data there are no licensing issues either. Some vendors may or may not require more restrictive licenses as a condition of selling you proprietary data.

I don't have a full time Internet connection… how do I use the map server to publish images? If you do not have a full time Internet connection you must install such a connection or find someone who has such a connection. Or, you could hire time from an ISP using a managed server that provides you with a virtual machine, like having your own machine connected full time to the web, but managed for you by the ISP.

How do I publish my maps to a web site I have at my ISP? Your ISP must install Manifold System on the machine that hosts your web site and both your .map file and generated web pages must be uploaded to that machine. Most people will do so via a managed server or co-location plan with the ISP. Because the map server runs extremely well on modern PCs that anyone can afford, another possibility is to install a full-time Internet connection (like a cable modem or DSL line) and run the server on your own machine. Even a relatively low-speed direct connection like a 384K uplink can handle thousands of users per day. Another option is to use an Application Service Provider (ASP) or consultant who can set up and operate your Manifold web page for you.

How do I customize the appearance of the generated web page? Change the HTML in the default.asp file and the style settings in the default.css style sheet. Advanced users can tinker with the scripts as well. Changing table structure, background colors and other design elements within these files can create radically different appearances. Add your HTML to customize the page with user instructions, titles and other texts.

Can I program the map server? Yes. By writing customized ASP or ASP.NET files one can create very sophisticated interactions with the project through the map server. This is an advanced topic that is described via the programming documentation in Help as well as with examples in the Free Stuff page on the manifold.net website.

How do I remove the small "Powered by manifold.net" text and hyperlink to the manifold.net IMS page? In Manifold System Professional Edition the logo cannot be removed since it is part of the view generated by the map server itself and is required to be present by the End User License Agreement for Professional Edition. In Manifold System Enterprise Edition the "Powered by manifold.net" text and hyperlink may be removed by unchecking the Logo box in the Export Web Page dialog. This is also possible, of course, when using a Universal Runtime license to deploy a Manifold IMS application to a web server.

Can I use Manifold IMS to publish more than one map from the same server? Yes. The Manifold map server can use more than one project at a time using different .map files and can even publish more than one component at a time from the same .map file. See Publishing Multiple Pages.

How do I run the map server in my cluster / web farm? The map server bundled with Manifold System does not automatically cluster across systems. A simple approach to distributing load between multiple servers is to use a round-robin proxy to distribute clients among your servers.
What are the browser requirements? Any modern browser can view pages generated by the map server. The browser must be able to execute scripts and to display .png images (or other image format specified in the IMS config.txt options). All "4.x" and later IE browsers may be used.

Can the map server run with HTML servers other than IIS? Yes. One can write web pages that use IMS under any HTTP server provided the execution environment can instantiate and work with COM objects. However, such usage is not supported by manifold.net since the main development environment and all default templates are targeted at IIS.

What is the IUSR_xxx account? Because it does not make sense to allow everyone on Internet to have free access to do whatever they want with our web server, Microsoft has thoughtfully provided an IUSR_xxx (xxx is the machine name) login that is automatically assigned to visitors interacting with the web server via Internet. Microsoft also has had the foresight to restrict the IUSR_xxx account so it cannot rampage around in our machine.

Very important: In 32-bit and 64-bit versions Windows Server 2003 and in 64-bit Windows XP the account used for Internet visitors is not the IUSR_xxx account as with earlier Windows versions. Instead, the NETWORK SERVICE account is used. When ASP .NET is employed the ASPNET account is used.

Windows Server 2003 and 64-bit Windows XP operators should understand the NETWORK SERVICE account is meant in all cases where this documentation discusses the IUSR_xxx account.

Web pages operating in an ASP.NET environment may require different permission settings than those operating in an ASP environment. For example, the default login used by ASP.NET is ASPNET, while the default login used by ASP is either the IUSR_xxx account or the NETWORK SERVICE account. When running in ASP .NET, the .map file and all other data being accessed from the ASP.NET environment must be readable by the ASPNET user account.

ASP .NET operators should understand the ASPNET account is meant in all cases where this documentation discusses the IUSR_xxx account.

When we set up an Internet application by putting files in the InetPub/wwroot folder hierarchy, by default visitors get reasonable IUSR_xxx account access to those files because Microsoft has set up those folders with inheritable permissions that grant the IUSR_xxx account access within those folders. However, if we want to use files that are not located in that folder hierarchy, we must explicitly grant permission to the IUSR_xxx account to read or execute such files. For example, if our website contains .asp files that instantiate an object that uses a .map file located somewhere else on our machine, we must make sure that the IUSR_xxx account can read the .map file.

Can Manifold IMS run on a Linux system? No. Manifold System runs only on Microsoft Windows operating systems.

How do I meet other developers working with IMS? Post on the Georeference forum. Visit the Forum page on the manifold.net web site or simply go directly to forum.manifold.net - if you are doing serious work with IMS, make sure to visit and participate in the forum where IMS programmers from all over the world meet to discuss IMS and exchange tips and advice.

Promote Your GIS Work

In just about any enterprise one must justify the resources invested into organizations and activities. Showing the tangible results of GIS work by publishing a cool IMS web site can be a spectacularly effective way of showing off your GIS work within your organization. It's easy to show off your GIS work on a web site that anyone with a browser can access from the convenience of his or her desktop. It is much easier to demo your work on a web site than it is to drag people one by one in front of a machine to show them a GIS demonstration.

Even if your mission does not require publishing a map-enabled website to Internet, it is usually a great idea to put up one or more IMS web sites on your organization's internal network just to make sure you get plenty of support within your organization for your GIS work.

If you are running a GIS business that could benefit from additional clients, running one or more IMS web sites that demonstrate your work is a great way to advertise your capabilities. Creating an IMS web site that provides some practical benefit for the industry you serve is a great way to generate links to your site. One good site that draws links from industry ezines and other sites can be worth tens of thousands of dollars in advertising per year.

Host Other Sites
Companies are now launching business plans to be Application Service Providers ("ASPs"), that is, to get into the business of providing hosting services over the Internet including the provision of GIS maps published over the web. At the present writing prices for such services are very high with startup fees of $1500 and recurring charges of $1500 per year for Internet map services that serve only 100 sessions ("hits") per day. Almost any computer that runs Manifold can host dozens of map server web sites at such low hit rates.

If you have a reasonably fast Internet link, IIS and Manifold System, you could provide hosting services for a fee to other Manifold users who do not want to host their own Internet server. Hosting Internet map server sites for government groups and other organizations is a great way to build a GIS consulting business as well, since such organizations often will want assistance in the preparation of the .map file used with the map server.

### About .PNG Format

The images served to the browser within the map window are created by Manifold IMS by default in .png format (other image formats may be specified in the IMS config.txt options). "PNG" stands for "Portable Network Graphics" and is also known recursively as "PNG is Not GIF".

.png (pronounced "ping" by .png experts) is a format originally developed to replace .gif. The .png format is lossless like .gif but is more efficient than .gif. In addition, .png can save alpha channel transparency. Although .jpg and .gif are more frequently used on the web as a matter of inertia, in simple form (without transparency) .png is universally supported by all modern browsers. .png images therefore can be used anywhere in a web page just like a .jpg or .gif.

Manifold uses .png because it is more efficient than .gif and suffers no loss of information in compression as does .jpg. By using .png Manifold is able to save at least 10% bandwidth as compared to using .gif. Since bandwidth in most sites is precious the simple use of a more efficient format allows at least 10% more simultaneous users at a given hit rate that could otherwise be accomplished with the same hardware and ISP service levels.

.png is also better than .gif because it is not subject to moronic patent threats from Unisys. See Just Say No to GIFs for a quick history on the threat to .gif usage from Unisys.

### Security and Access Permissions

See the Creating a Web Site topic for a discussion of security issues and access permissions.

### Troubleshooting

Manifold cannot run interactively with the usual user interface at the same time Manifold is functioning as a map server. All interactive sessions must be shut down before IIS can call upon the map server to serve map pages to the web. Conversely, if the map server has been run Manifold can not run interactively until the map server has been unloaded either via an iisreset command (the usual method) or by rebooting the system.

See the troubleshooting topic Problems with the Internet Map Server for detailed checklists of what might be wrong. Check to make sure that you are not running Manifold System Personal Edition, which does not include the map server. You must be running Professional Edition or greater to have the map server.

The number one problem with IMS reported to tech support is that users neglect to add the IUSR_ account (or, the NETWORK SERVICE account or ASPNET account if applicable) with access permissions to the .map file in use. Using Windows Explorer (do not just depend on the IIS management console or other server management console), right click on the .map file, choose Properties and verify in the Security that the IUSR_ account (or, the NETWORK SERVICE account or ASPNET account if applicable) for the system has necessary read and execute permissions.

### Note

You must be running Manifold System Professional Edition or greater to have the capabilities discussed in this topic. All Manifold editions except Personal Edition include the map server. If you are running Manifold System Personal Edition you will not have the capabilities discussed in this topic.
You must also have your Manifold license activated. At times inexperienced users attempt to use a Runtime license for an IMS server and then don't bother activating that Runtime license. That, of course, won't work.

Optimizing Performance
Creating a Web Site

This topic assumes the reader is familiar with Microsoft Internet Information Server (IIS) as well as web programming using HTML and Active Server Pages (ASP). Creating web sites with IIS is a straightforward process supported by a vast array of books and other educational resources. If you are not familiar with the operation of IIS, please get a good book on the subject and learn elementary IIS operation and administration before attempting work with Manifold IMS.

You must be sufficiently familiar with your Windows system to perform elementary tasks such as logging in as Administrator and setting Read security privileges on files and folders for local accounts such as the IUSR_account (or, the NETWORK SERVICE account or ASPNET account if applicable). If you do not know how to do this, please take advantage of the many educational resources available for your Windows version to learn how to do so before commencing work with Manifold IMS.

There are three steps to using Manifold IMS to publish to the Internet:

- Use Manifold to create a project containing the map or other component to be published. The entire rest of this documentation describes the many capabilities of Manifold at your disposal for creating cool maps.
- Create the files required for a map server web page using File - Export - Web Page. This step is described in the Map Server Overview topic.
- Create a web site using the map server web page files. The simplest way is to give users a URL that jumps directly to the created site.

**Very Important:** Before attempting to publish anything using Manifold IMS, please verify correct functionality of your IIS web server. An easy way to do this is to launch Internet Explorer and to load http://localhost/ into the URL address box. This will bring up the default page for your IIS installation or the Windows IIS help if no default page has been created. If you can’t browse a page served by IIS on your machine, stop and get IIS operational before proceeding.

A further check to make sure IIS is serving pages from the directories you think it is using. Perform this check by creating a simple index.htm page and make sure your index.htm page as well as other pages in your web site can be correctly browsed from the machine you intend to use as a server. Please resolve any problems with your IIS installation before attempting to use the Manifold map server.

The Export Web Page dialog creates several files: config.txt, default.asp, default.css and one or more accessory .asp files such as default_admin.asp. It also creates an images directory that contains image files in .png format for toolbar buttons and other controls. We use these files created by the dialog in our web site.

To create a web page using the map server:

1. Verify IIS is running on your machine.
2. In Windows Explorer, Create a directory within C:\InetPub\wwwroot in which the created files are placed. This example assumes we create a directory called "mexico" to publish an exported web page showing a map of Mexico. The location of the new directory is thus C:\InetPub\wwwroot\mexico. This directory must be created at least with Read permissions (which it has by default when a new folder is created in Windows) for the IUSR_account (or, the NETWORK SERVICE account or ASPNET account if applicable).
3. We assume you have already created a Manifold project and have saved it as a .map file. Copy the .map file to the folder in which it will be stored for use by the web site. Using Windows Explorer (not the IIS administration applet) verify the .map file has at least Read permission for the IUSR_account (or, the NETWORK SERVICE account or ASPNET account if applicable).
4. Launch Manifold and open the .map that will be used to create the web page.
5. Open the component that is to be published. Choose File - Export - Web Page.
6. In the Export Web Page dialog's Folder box, browse over to C:\InetPub\wwwroot\mexico. Specify the other boxes and checkboxes as desired and press OK. This creates the web site files within that directory.
7. You can now browse the created map page by entering this URL into the Internet Explorer Address box: http://localhost/mexico/
8. For performance and security reasons it is strongly recommended you create an IIS application for this web page as described below.

9. If for any reason the web page does not work correctly, please verify that the IUSR_ account (or, the NETWORK SERVICE account or ASPNET account if applicable), as at least Read permissions on the .map file involved and in all website folders.

**Note:** once a .map has been used to export a web page, it cannot be moved without altering the .config file used by the web site that specifies the location of the .map that is to be used.

**To create an IIS application:**

1. Open the Internet Information Services manager dialog in Windows [normally accessed from the Start button via Start - Programs - Administrative Tools - Internet Services Manager] and expand the Default Web Site.
2. Within the Default Web Site will be the mexico folder. Right click on the folder and choose Properties.
3. Push Create to create an application. Set execute permissions for Scripts only and High (Isolated) application protection. Press Apply.
4. Press OK to exit the Properties dialog.

When a .map file is in use for one application (map server or Manifold) it cannot be used in another application. This is similar to how most Windows applications work. For information on publishing multiple pages using multiple .map files or using one .map file but publishing different components from the .map file, please see the Publishing Multiple Pages topic.

**About IIS Applications**

An IIS application is any file that is executed within a defined set of directories in a web site. Creating an application designates a particular directory in the web site as the starting point directory (also referred to as the application root). All files and directories under that starting point directory are considered part of that application until another starting point directory is encountered. See the About Applications topic in the IIS documentation.

By placing our Manifold map server files in a particular directory and then designating that directory as an IIS application, we set up IIS so that any processes launched as a result of executing the default.asp file or other files in that directory will be launched as a separate application.

Strictly speaking it is not absolutely necessary to create an IIS application using the directory in which the default.asp file executes. However, this is highly recommended for better performance, reliability and control.

**Running the Web Site**

Web sites created within Microsoft’s Internet Information Server (IIS) can use .asp pages to dynamically create web pages served to browsers. .asp pages provide a sequence of instructions in an ActiveX scripting language that are used to dynamically create web pages on the fly. Based on the contents of the .asp page, IIS will create a stream of HTML content to feed to the requesting browser. Scripting commands embedded in the .asp file can be intermingled with ordinary HTML tags to create exactly the page desired. The default.asp and other .asp pages created by the Export Web Page dialog use javascript for scripting.

The examples above publish the generated web site immediately to the C:\InetPub\wwwroot folder that is the default publication directory for IIS. Browsers will be able to immediately view the web page if given the correct URL. Do not advertise the URL until an application has been created in Internet Information Services manager as noted above and the web site has been tested.

The URL to the new web page follows the usual IIS rules. Suppose we export the web page to C:\InetPub\wwwroot\mexico. Suppose further our web site is associated via DNS with a domain name called manifold.net. Our web site will be viewable at:

http://www.manifold.net/mexico/default.asp
Suppose we have an IIS server running on a Windows machine that is hooked up to the Internet via a cable modem or a DSL link so that it has a fixed IP address. Suppose also we don't have a domain name or DNS but we do have an IP address for the machine such as 192.201.44.168 (even if we have DNS we may not want to hassle with DNS and might prefer to simply used hardwired IP addresses for faster response). In that case we could tell users to browse our web site by referring to:

http://192.201.44.168/mexico/default.asp

Because Microsoft IIS is set up by default to launch a web page called default.asp or index.htm when browsing to a directory, we can also browse our web site using a URL such as

http://www.manifold.net/mexico or

http://192.201.44.168/mexico

The shorter form of the URL (with the default.asp implied) may be more convenient to provide to users.

Windows Server 2003

Very Important: For enhanced security, Microsoft's Windows Server 2003 product comes with Internet Information Server configured so that .asp pages are not enabled. .asp pages must be turned on within IIS for Manifold IMS to function correctly.

Very important: In 32-bit and 64-bit versions Windows Server 2003 and in 64-bit Windows XP the account used for Internet visitors is not the IUSR_ account as with earlier Windows versions. Instead, the NETWORK SERVICE account is used. When ASP .NET is employed the ASPNET account is used.

Windows Server 2003 and 64-bit Windows XP operators should understand the NETWORK SERVICE account is meant in all cases where this documentation discusses the IUSR_ account.

Web pages operating in an ASP.NET environment may require different permission settings than those operating in an ASP environment. For example, the default login used by ASP.NET is ASPNET, while the default login used by ASP is either the IUSR_ account or the NETWORK SERVICE account. When running in ASP .NET, the .map file and all other data being accessed from the ASP.NET environment must be readable by the ASPNET user account.

ASP .NET operators should understand the ASPNET account is meant in all cases where this documentation discusses the IUSR_ account.

IIS 7 and Vista Notes

By default, IIS 7 running in Windows Vista does not allow web applications to create files in the Temp folder. When using IIS 7 in Windows Vista you must allow web applications to create files in the Temp folder. The easiest way to do this is to run the following commands from the Command Prompt with Administrator privileges as follows:

To allow web applications in IIS 7 and Vista to create files in the Temp folder:

1. Click on the Windows Start button and then use the Start Search box.
2. Enter "command" to begin searching for the Command Prompt program. A list of matches will appear.
3. Right click onto the Command Prompt program and choose Run as Administrator. Enter the Administrator password.
4. This launches the Command Prompt window with Administrator privileges. Enter the following two command lines, pressing Enter after each line (enter each line as a single line):

icacls %windir%\serviceprofiles\networkservice\AppData\Local\Temp /grant Users: (CI) (S,WD,AD,X)
We can alter the appearance of a Manifold IMS web page by editing the files that create it:

- Styles used in the default.asp and other .asp pages are kept in the default.css cascading style sheet file. Fonts and colors used may be easily changed by editing the default.css style sheet file.
- Buttons and other images are stored in the images directory. These may be changed or replaced using other images. If the file names are changed (for example, to use .gif images instead of .png images) then the .asp files that use the buttons must be edited to change the names of the images as they are used in those files as well.
- The config.txt file specifies the size of the main map image and the location of the .map file used as well as the standard text used for title, subtitle and copyright lines. We can change the location or name of the .map file to be used by editing the config.txt file.
- We can alter the appearance of the page by editing the .asp pages. The .asp files created by Manifold consists of two types of code: javascript and ordinary HTML commands. The HTML code also may easily be changed to alter the layout, to add additional text to the page and so forth. For example, changes in the table that hosts the copyright text can be made to provide additional lines or legal notices that may be required. Scripting code should not be changed except by experts.
- We can utilize the created code within a frame set page that launches default.asp within one of the frames while using other frames for navigation, explanations, custom title bars or other graphics that provide our web page with a distinctive look and so on. It may be easier for novice webmasters to use frames to provide a custom look while leaving the Manifold .asp files unmodified.
- We can write our own .asp pages that use the WebServer object for a fully custom Manifold IMS application.

**Note:** Changes to config.txt or the .asp files will not take effect until the web application is unloaded. To unload the web application, launch a command prompt window and type iisreset to reset IIS. Changes in the .map file will not be acknowledged until the map server is forced to Reload the .map file, either using the Reload method of the MapServer object programmatically or using the Reo[ld button in the administrative default_admin.asp page.

See the IMS Config.txt Options topic for a list of options that may be used when configuring the config.txt file. Some of these options are not created through the Export Web Page dialog but must be manually entered into the config.txt file.

### Maintenance

The .map file used by the map server cannot be changed while it is in use for publishing the web page except through expert usage of the programmatic interface. The simplest way of changing it is to stop IIS, execute an iisreset command in a Windows Command Prompt window, launch Manifold, change the .map file, close Manifold and then restart IIS. The iisreset command unloads the map server as part of resetting IIS so that Manifold can execute in interactive mode.

It is also possible to change the .map file without restarting IIS. To do this, edit a copy of the .map file and save it under a similar name. For example, if we are using myfile.map with the map server we could edit a copy and save it under the name myfile2.map. Next, change the config.txt file to use myfile2.map instead of myfile.map and then in the Microsoft Internet Information Services manager dialog unload the web page application. Do this by right clicking on the application, choosing Properties and then clicking the Unload button (or, by using iisreset from the command prompt, or, if we have created an Admin page for the web site we could simply navigate to the Admin page and press the Reload button).

**Note:** After unloading a map server application that uses a large .map file the webmaster should browse the site and choose Zoom to Fit with all layers turned on. The first time a large .map file is loaded entirely into RAM the response of the server will be much slower as the entire .map file is loaded. Thereafter, server response will be faster.

For expert usage, IMS opens .map files for both reading and writing. This allows doing sophisticated analysis that involves creating temporary components, such as running queries the text of which is supplied by the user.
Tech Support Tip: The most frequent error users report is accidentally (during maintenance, updates, etc.) changing the security permissions on the .map file in use so that the IUSR_ account (or, the NETWORK SERVICE account or ASPNET account if applicable) no longer has read access permission to the .map file or to the folder in which the .map file resides.

For example, opening the .map file with Manifold can change the permissions on the .map file. If your web site worked fine and then stops working, check this and all other permissions to make sure the IUSR_ account (or, the NETWORK SERVICE account or ASPNET account if applicable) has the necessary access permissions. Saving a .map file with Manifold will preserve file permissions on Windows 2000 and later systems, but this is always something worth checking.

Refreshing Linked Drawings and Tables

Standard templates will refresh linked components as specified in the Refresh linked components option when creating the web page. However, for customized web sites .asp programmers may wish to utilize the properties and methods of the Drawing and Table objects.

The IsLinked method returns True if the component is linked and False otherwise. The LastRefreshed property returns the date and time of the last refresh for linked components and current date and time for non-linked components. The Refresh method refreshes linked components and does nothing for non-linked components. In the case of linked components the method returns True if it has succeeded and False otherwise. Refreshing a table bound to a linked drawing refreshes the drawing and vice-versa. Refreshing a linked table will update formatting based on the table’s columns. The RefreshAfter method does a Refresh if the component has not been refreshed for more than the given number of seconds.

These properties and methods allow programming a website that can force a refresh of a linked drawing or table when it is required by the logic of other parts of the website.

Using Images Linked from Image Servers

At times we may create a Manifold project that includes images linked from image servers. When using such projects within an IMS page, keep in mind that linked images may take a long time to render as image tiles are fetched from the remote image server. For example, an IMS project that contains an image linked from TerraServer won’t render that image on the website until the system fully downloads the entire required portion of the image from TerraServer.

The IMS page including the linked image can be no faster than the image server providing the image. If speed is of the essence, consider downloading the linked image into local storage, perhaps as a compressed image in ECW form.

See the Linked Images topic for links to image server topics.

Server Argument is Optional

When writing custom .asp pages, programmers should note that the Server argument within the WebServer.Create method is optional. Creating a WebServer object without a reference to an ASP Server (or a reference to an ASP-like wrapper for ASP.NET) puts IMS into a reduced functionality mode where it can render pictures, respond to zoom in, zoom out, center and other commands but cannot generate HTML reports. This allows the restricted use of Manifold IMS in ColdFusion and other non-ASP environments that are able to instantiate COM objects but are unable to simulate native ASP objects and are unable to utilize .NET.

Disk Requirements

Manifold IMS creates an image to serve to browsers. Each different view by any browser generates a different image. The image files used are created in the web page’s directory as temporary files in .png format (or other image format specified in the IMS config.txt options). Manifold will cache these images and will delete them after a twenty-minute time out period.

Although the image files served by the map server are small (depending on the size and content usually below 100KB in size), the size of temp files accumulated for a popular site can grow to tens of megabytes. Webmasters should make sure to have adequate free space for temporary files on the disk drives hosting the
web pages in use. In an era of large and inexpensive disk drives it is not normally a problem to be sure to have a few tens of megabytes free space available.

**Other Windows Versions**

The map server has been observed to work using the personal Internet server in Windows 98 and Me; however, these operating systems are not supported for use with the Manifold map server. Performance with 98 or Me (if it works at all) will be greatly reduced as compared to Windows Server 2003, 2000 or XP.

**Security Tips**

Microsoft IIS is a secure and highly reliable web server when correctly configured by the system administrator. Nonetheless, the many options made available within IIS to support the needs of experts can result in security problems if administered improperly. Because an IIS web server connected to Internet can be attacked by any Internet user from anywhere in the world, a few general IIS security measures should be applied to any web server connected to the Internet. These measures are not specific to Manifold IMS; they should be applied to every web server.

We recommend the following elementary steps:

- Use Windows 2003, 2000 or XP. Windows XP configures IIS by default with more security than does Windows 2000. Windows Server 2003 has the most default security.
- Use NTFS file systems.
- Do not allow anyone to work interactively, to read mail or to browse web sites on the machine that hosts your web site. If you must use the same machine interactively, make sure that user logins you employ do not have Administrator privileges. If a user with Administrator privileges just once opens a malevolent email attachment the web server itself could be infected with a wide variety of "backdoor" viruses or Trojan Horse attacks. Never read email or browse the web when logged in as Administrator.
- Install the latest Service Pack for Windows. Service packs include many security patches.
- Configure Windows Update to automatically download and install the latest Windows updates.
- Very Important: If you create a default_admin.asp page for your IMS site, make sure to change access permissions on it so that ordinary Internet browsers cannot use it. To do this, in Windows Explorer right click on the default_admin.asp file, choose Properties and choose the Security tab. Remove all entries for allowed user names except Administrator or whatever other login name you wish to allow access to the administration page. Apply the settings and press OK.
- Use an Administrator password that is called something other than "Administrator". Brute-force password cracking attacks have half the problem solved if they can assume there is a login called "Administrator" to attack.
- Use a seriously long (over 16 digits), randomly constructed password to make it difficult for brute-force password cracking assaults to guess your password.
- Install any supplemental security patches published by Microsoft after the last Windows Service Pack. Microsoft now has tools that can scan your system to determine if there are security patches published that have not yet been installed. Visit Microsoft TechNet at [http://www.microsoft.com/technet/default.asp](http://www.microsoft.com/technet/default.asp) and drill down to their Security pages for information on the latest security tools and patches.
- Install anti-virus software. Keep your anti-virus software updated with regular downloads from your vendor.
- Install Microsoft URLScan (a free download from Microsoft TechNet) or similar tool. URLScan is an ISAPI filtering tool for IIS that rejects a wide variety of malformed URL requests before they can hit IIS. It is very easy to use. It was published by Microsoft in 2001 and is an absolutely essential tool to prevent many different types of Denial of Service attacks. No doubt the functions provided by URLScan will continue to be offered by Microsoft either as independent tools or built into IIS. Manifold IMS works perfectly with URLScan.
- Apply Microsoft's IIS Lockdown Tool (a free download from Microsoft TechNet), or its successors, using Advanced Lockdown. Uncheck the box that disables support for Active Server Pages (.asp) and otherwise accept all of the defaults suggested by Advanced Lockdown. Manifold IMS works perfectly with Advanced Lockdown settings so long as Active Server Pages are still enabled. This tool is also very easy to use. Some recent editions of IIS may be shipped by Microsoft in lockdown mode by default.
- Do not run unnecessary services. If your server runs a web site only, do not install or enable additional services such as FTP, NNTP or others. If such services are already installed, use Internet Services Manager to stop them. Do not install any accessory software or Windows components that are not required.
Do not install unnecessary applications on your web server. Every application you install increases the attack surface that an adversary can exploit. For example, don't install things like Microsoft Office on a machine that will only be a web server.

Do not use your web server, ever, for Internet browsing or other applications. Some people press into use as a web server an otherwise underutilized machine that is occasionally used (out of boredom while waiting for some administrative task to complete, etc.) to browse the web or for other purposes. Dedicate a machine to web serving and don't use it for other purposes.

Do not connect your web server on a local area network to other machines unless you really know what you are doing with security. It is safest to keep it isolated and to use a USB drive to exchange files with other machines.

If you use Remote Desktop to work with your server, change the port it uses to some port other than the default. (Don't forget to leave this port open in your firewall.)

Learn to use Advanced TCP/IP settings for the Internet Protocol in Network properties for the network card in use. If your web site is intended only for specific machines (such as those on an Intranet), use IP security to deny access to any unauthorized machines (IP addresses). If you are connected to Internet, use TCP/IP filtering to permit only those TCP ports absolutely required to service your web site (typically, port 80 for HTTP and port 443 for HTTPS). Strict IP filtering will not allow services such as DNS (used if you are browsing from the web server) so a truly secure regime will limit utilization of the system to a web serving only.

Install a firewall such as Windows Firewall and learn to use it. Use a hardware firewall and/or software solution such as Microsoft's Internet Security and Acceleration Server. Hardware firewalls now cost well under $100. Configure your hardware firewall so that only those ports required for serving web pages are enabled, with all other ports disabled.

Install the latest updates for Manifold System from manifold.net.

Get a good book on Windows and IIS security. Read it carefully and apply the recommendations. Surf the web and read the many free resources on Windows and IIS security.

Participate in Manifold-L (email discussion list format) and the Georeference Forum at http://forum.manifold.net for Manifold System users. Ask questions of your more experienced colleagues and as you gain expertise yourself give back to the community by assisting newbies with security questions.

Very important: Although Manifold IMS can work with Microsoft security tools for IIS such as URLScan and the IIS Lockdown Tool, it is possible that other IIS applications installed on your system cannot work with these tools or require modifications to the default settings of these tools. It is critically important to read the documentation for these security tools.

When establishing security policies it is critically important to keep in mind the need for the IUSR_(or, the NETWORK SERVICE account or ASPNET account if applicable) Internet browser account to have read permissions for all files involved in the web site, including the .map file used as well as any database files used for linked drawings or linked tables. If a .mdb file is used, the IUSR_ account must also have read and write permissions for the folder in which the .mdb file is located, so that the map server process can create a lock file as is required when working with .mdb.

The idea of giving the IUSR_ account such permissions may worry novice webmasters. However, giving the IUSR_ account read permission and knowledge of the path to the .map file (which may be discovered by examining the config.txt file if a visitor knows enough about Manifold System) does not necessarily give the IUSR_ the ability to download the .map file. For example, the .map file could be located in a folder outside the InetPub hierarchy and so not be accessible for download. Likewise, if the folder containing any database files used is located outside the InetPub hierarchy these files cannot be downloaded either.

For novices, a workable approach until more can be learned about Windows security and IIS security is to create a folder, such as C:\lmsMaps, to place the .map file and any database files used in that folder and to grant IUSR_ read/write/execute permission on the folder and read permission for all files within the folder. Adjust the config.txt file in the actual web site (located somewhere in the InetPub hierarchy) so that the path to the .map file in use correctly notes the location in C:\lmsMaps.

Very important: In 32-bit and 64-bit versions Windows Server 2003 and in 64-bit Windows XP the account used for Internet visitors is not the IUSR_ account as with earlier Windows versions. Instead, the NETWORK SERVICE account is used. When ASP .NET is employed the ASPNET account is used.

Windows Server 2003 and 64-bit Windows XP operators should understand the NETWORK SERVICE account is meant in all cases where this documentation discusses the IUSR_ account.

Web pages operating in an ASP.NET environment may require different permission settings than those operating in an ASP environment. For example, the default login used by ASP.NET is ASPNET, while the default login used by ASP is either the IUSR_ account or the NETWORK SERVICE account. When running in ASP .NET, the .map
file and all other data being accessed from the ASP.NET environment **must** be readable by the **ASPNET** user account.

ASP.NET operators should understand the **ASPNET** account is meant in all cases where this documentation discusses the **IUSR**. account.

Note that permissions as discussed above are set using Windows Explorer. Right click onto the folder or file, choose **Properties** and then click on the **Security** tab.

**Troubleshooting**

See the troubleshooting topic Problems with the Internet Map Server for detailed checklists of what might be wrong.

The number one problem with IMS reported to tech support is that users neglect to add the **IUSR**. account (or, the **NETWORK SERVICE** account or **ASPNET** account if applicable) with access permissions to the .map file in use.

Using **Windows Explorer** (do not just depend on the IIS management console or other server management console), right click on the .map file, choose **Properties** and verify in the **Security** that the **IUSR**. account for the system has necessary read and execute permissions.

Take time to think through all permissions issues. The Internet access account **must** have permissions to get to all the data that is used in the web site. For example, suppose our IMS project uses a linked image. Because linked images use data from the Data Cache folder (the default), we must also be sure to give the **IUSR**. account (or, the **NETWORK SERVICE** account or **ASPNET** account if applicable) **read** permissions to access all files in that folder.

Do **not** take permissions for granted if an IMS site has problems. Check each folder and every file with Windows Explorer. For example, if you have opened a .map file with Manifold System it could be that the permissions on that .map file no longer include the **IUSR**. account (or, the **NETWORK SERVICE** account or **ASPNET** account if applicable). Saving a .map file with Manifold will preserve file permissions on Windows 2000 and later systems, but this is always something worth checking.

**About ASP.NET**

**ASP.NET** is a new technology introduced by Microsoft in Windows .NET servers. Microsoft ASP.NET is more than just the next generation of Active Server Pages (ASP). It provides a new programming model for creating network applications.

A key aspect of ASP.NET is that while just about any given task can be implemented in either ASP or ASP.NET, ASP.NET is overall easier to use, much faster, much more robust and much more flexible. Another key thing is that although in earlier editions of Manifold System we could use IMS with ASP.NET by creating a mixed ASP / ASP.NET application with the IMS portion handled by ASP, because IMS is now designed to function directly within ASP.NET environments we now can avoid using ASP at all and have our entire web application written in ASP.NET.

Of course, to use ASP.NET we must be running the Microsoft products that support it. Recent IIS versions are installed by default in "lockdown" mode so that not all facilities are available. In particular, ASP.NET is not enabled. Make sure to enable ASP.NET in your IIS installation using IIS Manager if you will create any IMS web sites utilizing ASP.NET.

**Dependent DLLs in ASP.NET**

ASP.NET allows use of dependent DLLs, which if the system is misconfigured will lead to error messages such as "A dynamic link library(DLL) initialization routine failed."

The most likely reason one or more DLLs are not getting initialized when loaded in an ASP.NET environment is that the system can not locate the dependent DLL modules to which it is linked. To work around this, include the path to the Manifold installation folder into the system PATH variable. That is, go to Control Panel - System - Advanced - Environment Variables and append the path for the Manifold installation folder (typically,
C:\Program Files\Manifold System) to the system (not user!) PATH variable. Then restart IIS, or, better yet, reboot the machine. This should get rid of the problem.

**ASPNET Permissions in ASP .NET**

Web pages operating in an ASP.NET environment may require different permission settings than those operating in an ASP environment. For example, the default login used by ASP.NET is ASP.NET, while the default login used by ASP is IUSR_xxx, where xxx is the machine name. The .map file and all other data being accessed from the ASP.NET environment must be readable by the ASP.NET user account. Use Windows Explorer to check the security settings for all files involved in your web site to make sure that ASP.NET can read them or execute them (in the case of executables such as manifold.exe). See the analogous discussion for the IUSR_xxx account.

**Tech Tip:** A .NET script invoked in the context of a web site can access the Document property of the Context object.

**Manifold System Edition Requirements**

You must be running Manifold System Professional Edition or greater to have the capabilities discussed in this topic. All Manifold System editions except Personal Edition include the map server. If you are running Manifold System Personal Edition you will not have the capabilities discussed in this topic.

If an IMS application attempts to use any features or functions that are part of the Business Tools or Surface Tools packages, it will fail if these extensions have not been installed on the IMS server.

The safest way to avoid configuration errors arising from inadequate licensing is to simply install a Universal Edition Runtime license on the web server machine when deploying an IMS application. Universal Edition includes all the extensions and the Universal runtime license is absurdly inexpensive.

**Required Geocoding Tools**

Manifold's street address geocoding capability becomes operational only when the optional Manifold Geocoding Tools package is installed. If you do not have the optional Geocoding Tools package, you will not be able to use street address geocoding functions within Manifold IMS or take advantage of the street address geocoding data provided on the Manifold downloads site for the United States.

Note that Manifold Universal Edition automatically installs the Geocoding Tools package. If you are using Universal Edition, you do not need to perform an extra Geocoding Tools installation as it has already been installed.

**Required Geocoding Data Sources**

In addition to installation of Geocoding Tools, for any street address geocoding capabilities the Manifold installation must have access to a geocoding data source. Once enabled by installation of the Geocoding Tools package, Manifold can use a variety of geocoding data sources, including the Manifold Geocoding Database for US streets provided on the Manifold downloads site, MapPoint North American or European editions, user-provided geocoding data extensions or Manifold Geocoding Servers accessed through the web.

See the Geocoding Data Sources topic for information on these sources as well as information on installing the Manifold Geocoding Database from the Manifold downloads site.

Optimizing Performance
IMS Config.txt Options

The config.txt file contains configuration information for the Manifold Internet Map Server (IMS) web pages that it accompanies. It is an ordinary text file that may be edited with Notepad. The config.txt file is automatically generated by the Export Web Page dialog. A typical config.txt file might look like:

```
component = Mexico Drawing 1
copyright = Copyright (C) 2002. All rights reserved.
cx = 500
cy = 400
file = C:\maps\mexico.map
queries =
subtitle = Click near an edge to pan map. Zoom in to see more layers.
title = Mexico
```

Once a website is generated, the config.txt file may be edited to make simple changes. For example, if the .map file used is moved to a different location the file = string can be changed.

Parameters (with typical examples of usage in the left column) may be:

- **antialiasLines** = true
  - Set to true or false to turn on or off antialiasing of lines.

- **antialiasTexts** = true
  - Set to true or false to turn on or off antialiasing of text.

- **clickAccuracy** = 10
  - Specifies the clicking tolerance in pixels when hyperlinks are clicked or the info tool is clicked on an object. The default accuracy is 4 pixels. Adding a line like that to the left will decrease accuracy to 10 pixels, so that a mouse click within ten pixels of the object will be as if the mouse were clicked directly onto the object.

- **Component = MyMap**
  - Name of component within the project to use. For example, if you have a map component named "MyMap" and you want that to be the component displayed by IMS.

- **configurationFolder = \%Manifold\%\Config**
  - The location of the Configuration folder, as given in Tools - Options, File Locations.

- **Copyright = Copyright (c) Acme Corp, 2005**
  - String to use in copyright position in standard templates.

- **country = United States**
  - Default country name for use by the geocoding engine.

- **cx = 800**
  - Width of the generated image in pixels.

- **cy = 600**
  - Height of the generated image in pixels.

- **dataCacheFolder = \%My Documents\%**
  - The location of the Data Cache folder, as given in Tools - Options, File Locations.

- **datumGridsFolder = \%Manifold\%\Grids**
  - The location of the Datum Grids folder, as given in Tools - Options, File Locations.

- **File = C:\data.map**
  - Absolute path to file to use.

- **geocodingDatabaseFolder = \%Manifold\%\GCDB**
  - The location of the Geocoding Database folder, as given in Tools - Options, File Locations.

- **geocodingExtensionsFolder = \%Manifold\%\GCDBX**
  - The location of the Geocoding Extensions folder, as given in Tools - Options, File Locations.

- **geocodingServers = Geocoder.us, mygcdbserver.org**
  - A list of Manifold Geocoding Servers to use by the geocoding engine, separated by commas.

- **hyperlinks = true**
  - Enable hyperlinks.
hyperlinksNew = false

If true, launch hyperlinks in new browser.

imageDesc = true

Embeds text information into the generated .png image.

logfile = c:\\mapserver.log

Specifies the path to the logfile, if used. By default, a logfile is not used. If used, a logfile will log useful parameters, for example, the time required to render the legend, if a legend is used.

logo = true

Available for Enterprise Edition users. If false, suppresses "Powered by manifold.net" logo.

mrSidDecodeUtilityPath = MrSidDecode.exe

The path to the MrSID Decode utility, as given in Tools - Options, File Locations.

mrSidInfoUtilityPath = MrSidInfo.exe

The path to the MrSID Info utility, as given in Tools - Options, File Locations.

ogcWmsCaps = C:\Inetpub\Wwwroot\filename

Specifies the path to the custom server capabilities document, if used, for OGC WMS.

preferMapPointToGeocodingDatabase = false

Set to true or false. If true, gives MapPoint priority over Manifold Geocoding Database as a geocoding data source for the geocoding engine.

Proxy = true

Proxy server address.

proxyAddress = http://netproxy:8080

Password used to login onto the proxy server.

proxyPassword = 123passwd

User name used to login onto the proxy server.

proxyUser = rootuser

Set rendering format. Supported rendering formats are gif, jpeg and png.

renderFormat = png

renderOptions = dither

Set rendering options. Supported rendering options are dither (supported for gif rendering format) and interface (supported for png rendering format).

renderQuality = 100

Set rendering quality in the range of 1 to 100, with 100 being the maximum quality.

queries = "Query 1", "Query 2", 52

Specifies queries used by IMS, using their names (such as "Query 1") or IDs (such as 52).

queryLimit = 100

Specifies the maximum number of records returned to the user by a query. The default value is 200.

refreshLinks = 60

Time interval over which linked components used in the website will be refreshed, in minutes. A value of 0 will refresh links on each browser access (can help debug server-side logic, not recommended for servers running in production mode due to heavy performance requirements).

refreshLinksOnOpen = true

Set to true or false. When true (the default), automatically refreshes linked components in opened MAP files. When false, does not automatically refresh linked components to save time.

scaleNumeric = true

Set to true or false. When true, causes scale (if used) to be reported as the horizontal extent of the visible region shown in the map server image. When false, scale is reported in absolute scale form.

scaleEnglish = true

Set to true or false. When true, turns on the use of English measurement units when reporting scale in horizontal extent form, otherwise scale will be reported in metric units.

selectionColor = 255:0:0

Specify color in either hexadecimal or decimal form to use
for selection color within IMS.

Hexadecimal colors are in "#rrggbb" form where rr, gg and bb are pairs of hexadecimal digits giving a hexadecimal number corresponding to the decimal number range from 0 to 255 for Red (rr), Green (gg) or Blue (bb). Leading zeros are significant, so that RGB values of 3, 5 and 6 are coded as 030506 in hexadecimal numbers. For example, selectionColor = #54BBB3 will set selection color to a light green-blue color instead of the default red selection color.

Decimal colors may be in two forms: either r:g:b form where r, g and b are decimal integer numbers in the range from 0 to 255 or as a single decimal number that is the decimal equivalent of a #rrggbb hexadecimal number.

selectionStyle = dashes

Controls the selection style used to display selections. Possible option values are: border, denseDots, mediumDots, sparseDots, and dashes. Case does not matter. For example, selectionStyle = border will change the selection style used to a border outline for areas.

smoothLargeVectorObjects = true

Set to true or false to turn smoothing of large vector objects on and off. Turning smoothing on increases performance at a slight cost in rendering quality.

Subtitle = Use the toolbar buttons to switch between zoom and pan modes.

String to use in subtitle position in standard templates.

Title = My Map

String to use in title position in standard templates.

useGeocodingDatabase = true

Set to true or false. Toggles the use of the Manifold Geocoding Database as a geocoding data source by the geocoding engine.

useGeocodingExtensions = true

Set to true or false. Toggles the use of geocoding data extensions as a geocoding data source by the geocoding engine.

useMapPointEurope = true

Set to true or false. Toggles the use of MapPoint Europe as a geocoding data source by the geocoding engine.

useMapPointNorthAmerica = true

Set to true or false. Toggles the use of MapPoint North America as a geocoding data source by the geocoding engine.

For example, we can edit the above config.txt file as follows:

```
component = Mexico Drawing 1
copyright = Copyright (C) 2005. All rights reserved.
cx = 500
cy = 400
file = C:\maps\mexico.map
queries = subtitle = Click near an edge to pan map. Zoom in to see more layers.
title = Mexico
scaleNumeric = true
scaleEnglish = false
```

This will cause the scale to be reported as the number of kilometers spanning the horizontal extent of the displayed map server image.
A useful way of seeing what a config.txt file looks like is to create a web site, checking the Save proxy connection and file locations in the config file option checkbox, and then open the config.txt file to see what Manifold has created.

**Manifold System Edition Requirements**

You must be running Manifold System Professional Edition or greater to have the capabilities discussed in this topic. All Manifold System editions except Personal Edition include the map server. If you are running Manifold System Personal Edition you will not have the capabilities discussed in this topic.

**Required Geocoding Tools**

Manifold's street address geocoding capability becomes operational only when the optional Manifold Geocoding Tools package is installed. If you do not have the optional Geocoding Tools package, you will not be able to use street address geocoding functions within Manifold IMS or take advantage of the street address geocoding data provided on the Manifold downloads site for the United States.

Note that Manifold Universal Edition automatically installs the Geocoding Tools package. If you are using Universal Edition, you do not need to perform an extra Geocoding Tools installation as it has already been installed.

**Required Geocoding Data Sources**

In addition to installation of Geocoding Tools, for any street address geocoding capabilities the Manifold installation must have access to a geocoding data source. Once enabled by installation of the Geocoding Tools package, Manifold can use a variety of geocoding data sources, including the Manifold Geocoding Database for US streets provided on the Manifold downloads site, MapPoint North American or European editions, user-provided geocoding data extensions or Manifold Geocoding Servers accessed through the web.

See the Geocoding Data Sources topic for information on these sources as well as information on installing the Manifold Geocoding Database from the Manifold downloads site.

- Optimizing Performance
IMS Queries

Web pages created with the Manifold map server can utilize queries that operate on the component being published. If any queries exist in the project they will be made available in the Queries pane of the Export Web Page dialog.

For example, if our project contains three queries as seen above, launching File - Export - Web Page will show them in the Queries pane as seen below:

Checking a query's checkbox will cause it to appear in the Queries pane of the generated web page. If we check all boxes in the Export Web Page dialog all three queries will appear in the web page:

Two of the queries are parameter queries - they allow user entry of a parameter and so are equipped with an edit box allowing user entry. The third query takes no parameter and so has no edit box.

Entering a value into a query edit box and pressing Query will launch the query.
The result is a table that lists the output of the query. Tables will appear either in a new browser window or in a frame in the same browser window depending on which template was used to create the web page. Any URL columns will have hyperlinks created for their entries in the table.

Optional templates used within the Export Web Page dialog will create different pages. The configuration seen in the browser window depends on choices made in the dialog. The illustrations shown in this topic use the Standard template, which is designed for use with newer browsers. The Compatible with 4.x browsers template uses a simpler style.

Tables in sites created with the Compatible template will be displayed in the same browser window, thus requiring a back command in the browser to go back to the map page.

Captions

The names of the queries are used for the text strings that appear in the Queries pane in the web page. The captions for the edit boxes are simply the name of the parameter variable used in the parameter query.

For example, the States with population query shown above contains the following SQL:

```sql
PARAMETERS exceeding LONG;
SELECT NAME, POP1990 FROM [States Drawing] WHERE POP1990 > exceeding;
```

The parameter variable exceeding is accepts user entry and is used within the query to process the SQL statements.

Manifold will use the name of the query, States with population, together with the name of the parameter variable, exceeding, to construct the captions for the query. When creating a Manifold project for publication to the web it therefore is important to think ahead when naming queries and parameter variables so that the resulting captions are reasonably well self-documenting.

Rules

When using queries in web pages the following rules must be observed:

- All queries in the project will be listed in the Queries pane in the Export Web Page dialog, even those that cannot legally be used within a map server site. It is the Manifold operator's responsibility to know the contents of the queries and to choose acceptable queries.
- Only SELECT queries may be chosen for use in the generated site.
- The Manifold operator is responsible for selecting queries that operate within the component being published. For example, if a project contains a query that reference a drawing that is not part of a map that was published, the query should not be chosen for use in the site.
- Queries output a maximum of 200 records to a table on the web page.
Launching a new query will eliminate the results of the previous query.

To avoid errors, it is strongly recommended that projects used with the map server contain no unnecessary or unusable components.

**Examples**

The **States matching** query seen in the illustration at the beginning of this topic contains:

```sql
PARAMETERS pattern TEXT;
SELECT NAME FROM [States Drawing] WHERE NAME LIKEX pattern;
```

It uses the **LIKEX** operator to find the names of states matching the pattern provided by the user.

The **10 longest roads** query contains:

```sql
SELECT TOP 10 LENGTH, TYPE, ROUTE FROM [Roads Drawing]
ORDER BY LENGTH;
```

There is no parameter used in this query. It simply always selects the ten longest roads based on the contents of the **Length** field.

**Panning to Selected Objects / Suppression of ID Field**

Objects are not selected by queries in Manifold unless the **ID** system field is selected by the query. For example, if we have a drawing of provinces that each has a name, the SQL fragment ...  

```sql
SELECT Name from [Provinces Table] WHERE...
```

... will create a table, but it will not select the objects associated with the records that appear in that table. In contrast, the fragment...

```sql
SELECT ID, Name from [Provinces Table] WHERE...
```

... will select the objects as well as creating the table.

If the first SQL fragment is part of a query that is used in a Manifold IMS web site the output of the query will be a table, but the IMS map window will not be panned or zoomed. If the second IMS fragment is used, a table will be created, the objects will be selected, and the IMS map window will pan to the center of the selected set of objects and will zoom to fit the selection.

Since we normally do not want to show internal system fields such as the **ID** field to people browsing our web site, the **ID** field will not be displayed as part of a table created by an IMS query.

**Geocoding and Queries**

The Manifold geocoder is accessed in IMS applications by using queries utilizing the geocoding SQL extensions. Manifold SQL includes geocoding SQL extensions that operate with Manifold’s geocoding engine to perform spatial operations based upon an address string or zip code. Geocoding queries will not function unless either Manifold's US streets geocoding database is installed or Microsoft’s MapPoint program is installed. If MapPoint is used, performance will be lower but coverage will extend to all countries covered by the MapPoint editions (North America and/or Europe) installed. See the Geocoding with MapPoint topic if MapPoint is to be used. Note that Internet access permissions must be adjusted (see below) if MapPoint is called from IMS.

Geocoding extensions will not work with Manifold IMS using the Manifold US streets geocoding database unless the geocoding database is installed within the Manifold application installation folder (normally, C:\Program Files\Manifold System). Therefore, the US streets geocoding database should be installed in the Manifold application installation folder on machines on which Manifold IMS operates. Geocoding queries using MapPoint
will work so long as MapPoint is correctly installed on the server system regardless of the installation directory used.

Drawings must be projected for geocoding extensions to function correctly.

**Boolean CloseToAddress(Number ID, String Address, Number Distance, [String Unit])**

Given an object ID, an address string, a distance and an optional distance unit determine if the object lies within the specified distance of the address.

**Boolean CloseToZip(Number ID, String Zip, Number Distance, [String Unit])**

Given an object ID, a ZIP code string, a distance and an optional distance unit determine if the object lies within the specified distance of the zip code centroid.

**Number DistanceToAddress(Number ID, String Address, [String Unit])**

Given an object ID, an address string, and an optional distance unit computes the distance between the object and the address.

**Number DistanceToZip(Number ID, String Zip, [String Unit])**

Given an object ID, a ZIP code string, and an optional distance unit computes the distance between the object and the zip code centroid.

**Notes on usage:**

- If an object is a line or an area the object's centroid is used for distance calculations.
- If an address string produces more than one match, the system automatically selects the closest of the building-level matches (possibly with an "unknown street name, possible misspelling" error).
- If an address string produces no building-level matches, `CloseToAddress` returns `False` and `DistanceToAddress` returns `-1`.
- If a zip code string is invalid (no matches in the geocoding database) `CloseToZip` returns `False` and `DistanceToZip` returns `-1`.
- If the optional distance unit is omitted, the system will use the native measurement unit of the drawing or meters if the drawing is not projected.
- Distances are great circle distances computed over a WGS84 ellipsoid and are accurate to 1 meter.
- The geocoding functions cache returned geocoding data between subsequent calls.
- Functions can be used from IMS as long as the geocoding database is located within the Manifold application installation folder (usually `C:\Program Files\Manifold System`).

**Geocoding Function Examples**

```
SELECT * FROM Dealers
WHERE CloseToAddress(ID, "330 Lytton Ave, Palo Alto, CA, 94301", 10, "mi")
```

```
SELECT * FROM Dealers
WHERE DistanceToAddress(ID, "330 Lytton Ave, Palo Alto, CA, 94301", "mi") <= 10
```

```
SELECT * FROM Dealers
WHERE CloseToZip(ID, "94301", 10, "mi")
```

```
SELECT * FROM Dealers
WHERE DistanceToZip(ID, "94301", "mi") <= 10
```
All four examples have a similar function. The first query selects all objects in Dealers that are within 10 miles of the given address using the CloseToAddress function, while the second example performs the same task using the DistanceToAddress function. The third and fourth examples perform the same functions using the 94301 ZIP code.

To keep the user interface simple and to avoid the complication of dealing with possible user errors when entering address information into forms, many web applications with IMS will use the CloseToZip or DistanceToZip functions since these require the user to merely enter the ZIP code correctly. For many applications, such as locating a dealer, finding the closest objects to the ZIP centroid provides acceptable accuracy.

See the Units topic for a list of unit abbreviations that may be used to specify optional distance units.

MapPoint and IMS

MapPoint geocoding will normally not work from IMS unless we map anonymous Internet connections to a user account that has more enhanced permissions than the default Internet access IUSR_xxx account.

To enhance permissions for the Internet access account:

1. Create a regular user account with default permissions that is a member of the Users group.
2. Open Control Panel - Administrative Tools - Internet Information Services (or the equivalent dialog in your version of Windows).
3. Right click the folder that contains the published website, select Properties, switch to Directory Security and click Edit under Anonymous access and authentication control.
4. Set the user account used for anonymous access to the account created in step 1 above.

See the Geocoding with MapPoint topic for use of MapPoint as an auxiliary geocoder.

Tech Tip

When developing on one machine and publishing on a different machine, make sure the machine that is actually running the map server is a fully up-to-date Windows machine with all required updates in place just like the machine that was used to create and test the project.

For example, Manifold System requires that Microsoft Internet Explorer 5.5 or later (preferably the most recent IE version) has been installed to make sure that all Windows components, including scripting components, have been updated. Occasionally, server machines used as IIS hosts might not have IE installed or might not have the latest version of IE installed because the server is not used interactively to browse the web.

In such cases a Manifold project and web page might work fine on the development machine but then not work correctly (queries fail, etc.) when installed on the server. If this happens, check the server machine to make sure Windows is fully updated as required by your Manifold System installation notes.

Also make sure to verify that the web server machine has all required Manifold licensing and accessories installed. For example, if an IMS web site uses a project that depends upon Enterprise Edition features the web server machine must also have a license for Enterprise Edition and the project must be correctly configured in the web server so it can connect to the Enterprise server it uses. Likewise, if geocoding queries are used the web server machine must have the Manifold Geocoding Data product installed and be licensed for its use.

Troubleshooting

See the troubleshooting topic Problems with the Internet Map Server for detailed checklists of what might be wrong.

The number one problem with IMS reported to tech support is that users neglected to add the IUSR_account the IUSR_account (or, the NETWORK SERVICE account or ASPNET account if applicable) with access permissions to the .map file in use. Using Windows Explorer (do not just depend on the IIS management console or other server management console), right click on the .map file, choose Properties and verify in the Security that the IUSR_account for the system has necessary read and execute permissions.
Take time to think through all permissions issues. The Internet access account must have permissions to get to all the data that is used in the web site. For example, suppose our IMS project uses a linked image. Because linked images use data from the Data Cache folder (the default), we must also be sure to give the IUSR_ account (or, the NETWORK SERVICE account or ASPNET account if applicable) read permissions to access all files in that folder.

Windows security and access permissions can be confusing, but it should be remembered that these issues are Windows issues and not Manifold issues. For example, if an IMS project includes calls to DBMS tables resident in an external DBMS, such as SQL Server, the application will operate using the security context of the ASP or ASPX page comprising the IMS application. Resolving connection issues (such as a failed login to the SQL Server) must be resolved with an informed understanding of Windows integrated authentication.

When troubleshooting such problems, the first objective should be to make sure you thoroughly understand all Windows security mechanisms, especially those involved with IIS applications.

**Note**

You must be running Manifold System Professional Edition or greater to have the capabilities discussed in this topic. All Manifold editions except Personal Edition include the map server. If you are running Manifold System Personal Edition you will not have the capabilities discussed in this topic.

Geocoding with MapPoint
Publishing Multiple Pages

Manifold IMS can publish multiple pages at once. There are two main ways to publish multiple pages:

- Publish several different pages using several different .map files.
- Publish several different pages using several different components within the same .map file.

**Multiple Pages using Multiple .map Files**

To publish multiple map files, create a separate directory for each web page to be created. Place the config.txt, default.asp and default.css files created for that page by File - Export - Web Page into the directory along with an image subdirectory containing the standard toolbar button images.

For example, if we published a map of Mexico we might place that in C:\inetpub\wwwroot\mexico\ and if we also published a world map we might place that in C:\inetpub\wwwroot\world\.

Create a separate IIS application for each directory containing the files for that page.

For example, in the screenshot above we see an Internet Services Manager of a web site with several IIS applications. Three of them (manifold, mexico and texas) are Manifold IMS applications created using three different .map files. Each of the directories contains the config.txt, default.asp and default.css files created for that web page by the File - Export - Web Page dialog. Each of the application directories also contains a directory called images with the standard image files for toolbar buttons and controls that is also created by the Export Web Page dialog.

It may seem wasteful to duplicate the images directory for every application, but the images used are of negligible size. Duplicating the images directory for each page served by the map server simplifies the default.asp code and also allows easy customization of the appearance of toolbar buttons for each page if so desired.

**Multiple Pages using the Same .map File**
Different components from the same .map file can be used with different map server pages. However, all map server pages must be part of the same IIS application. To do this, create one directory with several subdirectories for each page. Create the IIS application on the parent directory.

Suppose, for example, we have created a usa.map file containing several drawings showing different data sets for the United States. One web page will show a map that contains several layers of interest to education. Another will show a map containing income layers and a third will show population layers.

We might create directories as follows:

- C:\InetPub\wwwroot\usa with subdirectories
- C:\InetPub\wwwroot\usa\education
- C:\InetPub\wwwroot\usa\income and
- C:\InetPub\wwwroot\usa\population

The education directory would contain the config.txt, default.asp and default.css files for the education map. The income directory would contain the config.txt, default.asp and default.css files for the income map, and the population directory would contain the files for the population map. The config.txt files for all three pages would use usa.map as the originating map file; however, the component used would be different.

We would create the IIS application on C:\InetPub\wwwroot\usa. All processes launched, including those for the default.asp files in education, income and population would thus be part of the same application and could use the same .map file.

The illustration above shows the application and directory structure within Internet Service Manager.

**Troubleshooting**
See the troubleshooting topic Problems with the Internet Map Server for detailed checklists of what might be wrong.

The number one problem with IMS reported to tech support is that users neglected to add the IUSR_ account to the map file in use. Using Windows Explorer (do not just depend on the IIS management console or other server management console), right-click on the .map file, choose Properties and verify in the Security tab that the IUSR_ account for the system has necessary read and execute permissions.

Take time to think through all permissions issues. The Internet access account must have permissions to get to all the data that is used in the web site. For example, suppose our IMS project uses a linked image. Because linked images use data from the Data Cache folder (the default), we must also be sure to give the IUSR_ account (or, the NETWORK SERVICE account or ASPNET account if applicable) read permissions to access all files in that folder.

Note

You must be running Manifold System Professional Edition or greater to have the capabilities discussed in this topic. All Manifold editions except Personal Edition include the map server. If you are running Manifold System Personal Edition you will not have the capabilities discussed in this topic.

Optimizing Performance
Optimizing Performance

For a given level of hardware speed and capacity, performance for a Manifold IMS map server page depends upon Windows system settings (including IIS settings) as well as the configuration of the map server and the .map file it uses.

The map server uses Manifold to generate images served via the web page. The basic performance of the map server will be similar to that of Manifold during interactive usage and is subject to the same optimization tips suggested for Manifold in the Performance Tips topic. Make sure you follow all the performance tips listed in that topic.

Additional performance tips of special interest to IMS:

**Manifold IMS Performance Tips**

- **Use 64-bit Windows and 64-bit Manifold** - 64-bit operation is significantly faster than 32-bit operation in IIS applications because larger amounts of memory can be more effectively used.

- **Export smaller sized web pages** - Generating a map server image of 400 x 300 requires less computation than an image of 800 x 600. Larger views will usually include more objects and so require greater display computation. In addition, serving larger images means moving larger amounts of pixels into the created image and then transmitting those larger numbers of pixels down the Internet pipes connecting the server to the user's browser.

- **Avoid use of very large .map files** - The larger and more complex the component the slower will be the response of the map server. Just as with interactive use of Manifold, performance of the map server will improve as the user zooms in so that fewer objects participate in the display.

- **Avoid unnecessary use of images and surfaces** - Images and surfaces can be slower than drawings for the information they provide. The Manifold map server will happily serve images and surfaces but these should not be used as casual substitutions for drawings when a drawing will do as well and will provide higher performance.

- **Use Compressed Images** - Using a linked image with an ECW or JPEG 2000 file is vastly faster than ordinary images, a difference of virtually instantaneous zooming and panning as opposed to possibly minutes for very large images.

- **Use Oracle Spatial or a spatial DBMS for Images** - Images linked from an Oracle Spatial server or from a spatial DBMS managed by Manifold will be extremely fast at virtually any size. Linking images from Oracle requires Enterprise Edition, but any Manifold edition can link images from spatial DBMS managed by Manifold.

- **Install Ample RAM** - As components in the .map file are used, they are read off disk and brought into RAM. Once a component is in RAM, it stays there unless the RAM must be freed for some other purpose. The map server can work faster if the components it needs are already in RAM. As the parts of the .map that are served are brought into RAM and stay there (as a result of normal Windows RAM caching) access speed will increase. This only works, of course, if there is enough RAM so that the cached .map data is not flushed from RAM because some other Windows application needs the RAM. RAM is cheap: install many gigabytes if you can do so. Choosing a server motherboard that can host 16 or 32 GB of RAM is much less expensive than having to use more than one server machine.

- **Run Multi-core Processors** - Almost anything that can be done to avoid having to scale out to multiple server machines is worth the cost and effort. Choose a motherboard with two or more processor sockets and then install quad-core processors to get eight or more processor cores in action. If you have multiple processor cores don't forget to configure multiple worker processes. For example, if you have a quad core processor and want to max out all four cores, configure your web application to have four worker processes.

- **Eliminate initial load lag** - The first time a very large map is served the map server will be slow to respond while the .map is opened and loaded for the first time. After creating a site the webmaster should browse the site and choose Zoom to Fit with all layers turned on. This will load the entire .map file into RAM. Thereafter, server response will be faster.

- **Match component projections to maps** - If a map is served, all layers in that map should have exactly the same native projection as used by the map. This will eliminate any need to re-project on the fly. This is especially important for images and surfaces.

- **Delete unused components from the .map file** - If the .map file contains many components other than those published in the web page the map server will respond slightly more slowly than if the .map file contained only those components being published. Delete any unused components from the .map file. This is normally a very minor impediment to maximum performance. However, if the .map file contains very large components that are not used the performance difference may be noticeable.

- **Delete unused data from components** - If the web site does not enable the Find tool or use queries there is no point in publishing a drawing that contains data attributes. Delete the columns in the drawing's table. When publishing maps that contain more than one drawing the Find tool will list all
fields in all drawings in the map. Delete all fields that you do not want users to be able to employ in Find. This will reduce the size of the .map file.

- **Avoid use of unnecessarily detailed data** - A web site that provides overall, national data should not use extremely detailed high-resolution drawings. Use Normalize Topology with appropriate Location Precision settings to simplify drawings. This is often a key step to increasing the speed of redisplay, pan, zoom, etc.

- **Use Zoom Ranges to present the level of detail required** - Suppose we would like to show a national map for user orientation when zoomed out but we would also like to show very detailed shorelines when users zoom in. Create a map using two drawings: a highly detailed drawing plus a second, low resolution drawing created from the first by generalizing with Normalize Topology to a lower Location Precision value. Assign zoom ranges to the drawings so that the low-resolution drawing is the only drawing displayed when zoomed out and the high-resolution drawing is the only drawing displayed when zoomed in. When users browse the map in a zoomed out view the display will be fast because a fewer number of coordinates need be used to display the low-resolution drawing. When users are zoomed in the high-resolution drawing will become visible; however, only a portion of the high-resolution drawing will be seen in a zoomed in view so the display will still be fast.

- **Store the .map file used on a fast, local hard disk** - When the Manifold map server operates it accesses the .map file that was used with File - Export - Web Page to create the web page. If the .map file is located on a slow hard disk or on a different machine that must be accessed via a local area network then performance will not be as fast as if the .map file was immediately available on a local, fast hard disk.

- **Avoid using intrinsic fields in queries**. For example, if the length of a road line must be used, do not compute the length on the fly via the Length (I) intrinsic field. Instead, create a new column called Length and copy the contents of the Length (I) intrinsic field into this new column using the transform toolbar Copy command. When an intrinsic field is used in a query a small computation must be performed for every record for every query. If the intrinsic field is copied to a regular column the computation is done only once. The query can then use the regular column for faster operation.

- **Avoid unnecessary refreshes**. Depending on the technology employed, the speed of the communications channel and the amount of data involved each refresh can impact performance. There is no need to refresh every minute if data can only change significantly once per hour.

- **Avoid slow linked components**. While linked components are the perfect solution in many applications, at times it does not make sense to use them. At other times it makes sense to use linked components but only if used correctly, such as by an informed, expert choice of which type of linked component to use. For example, it may be tempting if we need a background image for a web site to simply link in an image from an OGC WMS server to which we have access. However, thereafter whenever we refresh links our web site will be at the mercy of whatever performance is provided by the OGC WMS server. It would be faster and better (assuming the background image does not change, as they rarely do) to convert that image into a local image such as an ECW image. See the discussion of refresh issues in the Map Server Overview topic.

- **Use EPSG projections for OGC WMS**. If the coordinate system (projection) used by a served component is not supported by the EPSG schema used by the OGC WMS community, Manifold will have to re-project the component on the fly into a Projection (I) intrinsic field. Instead, create a new column called Projection (I) and copy the contents of the Projection (I) intrinsic field into this new column using the transform toolbar Copy command. When an intrinsic field is used in a query a small computation must be performed for every record for every query. If the intrinsic field is copied to a regular column the computation is done only once. The query can then use the regular column for faster operation.

- **Use fast database technology**. Manifold works with virtually all DBMS technologies, which is great for flexibility but also gives us the ability to choose either very slow or very fast technologies. For example, some ADO .NET connections can be 600 times faster than an ODBC connection to the very same data source. Since many Manifold IMS web sites will include the use of some database technology (for example, if linked tables are used or linked drawings) it is important that we choose such technology wisely. In the case of linked tables if the data originates in a slow technology such as an Excel .xls file it will usually make sense to upgrade to a very fast technology, such as a SQL Server table accessed via ADO .NET or an Oracle table that can be accessed via OCI. As a rule of thumb, the fastest connections for storing attributes are to use ADO .NET with SQL Server or to use Oracle (which automatically uses OCI). The fastest geometry storage for large applications is to use a spatial DBMS such as SQL Server 2008 spatial, the Manifold spatial extender with SQL Server 2005, IBM DB2 with Spatial Extender, PostgreSQL/PostGIS or Oracle (taking advantage of Oracle Spatial or Locator services in Oracle XE or in standard Oracle).

- **Very Important**: If you create a default_admin.asp page for your IMS site, make sure to change access permissions on it so that ordinary Internet browsers cannot use it. To do this, in Windows Explorer right click on the default_admin.asp file, choose Properties and choose the Security tab. Remove all entries for allowed user names except Administrator or whatever other login name you wish to allow access to the administration page. Apply the settings and press OK. Neglecting this important step will not create a security breach in that hackers will be able to steal your data, but it will allow a malevolent user to effectively shut down your map server by repeatedly causing it to Reload .map files.
- Create an application and consider using High (isolated). - Create an application on the directory in which the web page is located and run it with high isolation. This runs the map server process as an isolated process outside of the IIS process and separate from any other applications running on IIS. This helps performance slightly (albeit at the cost of creating temporary files for every user), and also isolates the application so any errors in the scripts or map server application won't bring down IIS or any other application. For performance reasons, don't run more than ten IIS applications as High (isolated). To run additional map server applications beyond ten, if the map server application is well debugged (that is, the scripts used in default.asp and other files are well debugged), use Medium (pooled) for the additional applications. Medium pooling might also be a good idea to reduce the creation of per-user temp files (see comments below).

- Don't enable session state - Within the IIS manager, in Properties - Configuration - App Options uncheck Enable session state. The Manifold map server does not use sessions so this can be unchecked if desired to eliminate the overhead of maintaining session state. In the same dialog it is a good idea to also uncheck Enable parent paths if desired. This has no impact on performance but it does improve security. Unchecking this box means the application can not refer to anything in higher directories. The map server application itself only refers to files within its own directory or subdirectories such as the images folder.

- Enable object pooling - If there are more than about 10 simultaneous users, enable object pooling. This is done in the Control Panel - Administrative Tools - Component Services manager. Drill down into COM+ Applications and find your map server application. Drill down into Components for that application and right click on the component there and choose Properties. Object pooling settings are on the Activation tab. Check the Enable object pooling box. The pooling parameters may be left on default settings.

**System Configuration Performance Tips**

- Store the .map file used on a fast, local hard disk - When the Manifold map server operates it accesses the .map file that was used with File - Export - Web Page to create the web page. If the .map file is located on a slow hard disk or on a different machine that must be accessed via a local area network then performance will not be as fast as if the .map file was immediately available on a local, fast hard disk.

- Configure temp folders on a separate, fast hard disk - Putting temp folders on a separate hard disk allows "overlapping head seeks" so that the disk drivers can command a head movement on the disk(s) holding the temp folders at the same time heads are moving on whatever disk(s) host the rest of what is going on in Windows. This is a fine point, but not one to be overlooked if you are trying to wring maximum speed out of your system. Head motions are the slowest thing in the system so we don't want to waiting around for one head motion to finish before we get going on the next.

- Use Large Disks and RAID - Large disks are faster than smaller disks. Use modern interfaces such as SATA and configure several hard disks in a striped RAID array for speed.

- Install lots and lots of RAM - Installing plenty of dynamic RAM is often the most efficient way to enable a server to serve more users faster. RAM is now so inexpensive (under $60 for a gigabyte) that it makes sense even for a hobbyist to install two or three gigabytes of RAM. If you are running an older motherboard that can hold only one and a half gigabytes, fill it up with the maximum amount of RAM right away it even if you don't feel you need it because eventually memory for older motherboards will be difficult to get.

- Use a fast processor - A faster processor will be able to serve more users. Upgrade to a gigahertz class processor.

- Use a Quad Core 64-Bit Processor - Quad-core processors do not cost significantly more than dual-core or single-core processors. Use 64-bit hardware with 64-bit Windows and 64-bit Manifold. Using 32-bit software and hardware in a web server application is a terrible waste.

- Use multiple processors or multi-core processors - Each new release of Manifold adds more functions that are multi-threaded. For example, Manifold will use more than one thread to render image libraries if more than one processor or processor core is available on the computer system. Therefore, image libraries will render faster on multiprocessor or multi-core processor systems such as those using two sockets to host a quad-core processor in each socket.

- Use Windows Server 2003 or XP - Windows Server 2003 provides the best performance. Windows XP provides slightly better performance than Windows 2000. Do not use older Windows releases. Vista is cool, but at the present writing it is not as fast as Windows Server 2003 or XP x64.

- Deploy a server farm - Like any web application, given enough users even a fast IMS application can be overwhelmed if only a single machine is used. Novice webmasters are sometimes surprised to learn that large sites serving many visitors like Google, airline reservation sites or mapping sites don't just run on a single computer but are hosted by hundreds or even thousands of computers configured in a server farm. If we want to compete with a huge site hosting millions of visitors per hour, no matter how fast Manifold may be we too may need to deploy a warehouse full of servers.

- Plan to use NVIDIA CUDA - Try to choose a server motherboard that can support at least one NVIDIA CUDA-capable GPU. Although this technology is just getting started, each new release of Manifold is expected to make more and more use of it. May as well be ready.
About IIS Applications

An IIS application is any file that is executed within a defined set of directories in a web site. Creating an application designates a particular directory in the web site as the starting point directory (also referred to as the application root). All files and directories under that starting point directory are considered part of that application until another starting point directory is encountered. See the About Applications topic in the IIS documentation.

Different components from the same .map file can be used with different map server pages. However, all map server pages must be part of the same Application.

About Object Pooling

Manifold components support object pooling, which avoids the overhead of creating new objects in highly loaded servers. Normally, when a process needs an object it is created on the fly using the component's class factory to create a new object. When object pooling is turned on objects that are created are retained in a pre-built pool of objects. When an object is needed an object from the pool is activated if one is available. Pooled objects are returned to the pool when no longer needed.

Suppose 20 users at once hit the web site. The first time the server experiences this peak load enough objects to service the 20 users will be created. As load drops, objects will be returned to the object pool. Thereafter as long as the load stays under 20 simultaneous users no objects need to be created: they will simply be activated from the pool. If load grows again and peaks at 25 users, a few more additional objects will be created since the objects in the pool will not be enough to service demand. Thereafter, enough objects will be in the pool to serve up to 25 simultaneous requests.

Logging

Manifold IMS supports logging. To enable logging, edit the config.txt file for a page and add the following line:

    logfile = c:\mapserver.log

where "c:\mapserver.log" is the fully qualified path name to the desired log file. The log file will be written in CSV format using field names that are self-describing. ticks is the number of 1/1000ths of a second spent serving the image. It's safe to use the same log file for different instances of the map server.

Be careful when enabling logging. It is always easy to turn on a logging function and then forget it has been enabled until the log file grows to a huge size.

Security Tips

Microsoft IIS is a secure and highly reliable web server when correctly configured by the system administrator. Nonetheless, the many options made available within IIS to support the needs of experts can result in security problems if administered improperly. Because an IIS web server connected to Internet can be attacked by any Internet user from anywhere in the world, a few general IIS security measures should be applied to any web server connected to the Internet. These measures are not specific to Manifold IMS: they should be applied to every web server.

We recommend the following elementary steps:

- Use Windows 2003, 2000 or XP. Windows XP configures IIS by default with more security than does Windows 2000. Windows Server 2003 has the most default security.
- Use NTFS file systems.
- Do not allow anyone to work interactively, to read mail or to browse web sites on the machine that hosts your web site. If you must use the same machine interactively, make sure that user logins you employ do not have Administrator privileges. If a user with Administrator privileges just once opens a malevolent email attachment the web server itself could be infected with a wide variety of "backdoor" viruses or Trojan Horse attacks. Never read email or browse the web when logged in as Administrator.
- Install the latest Service Pack for Windows. Service packs include many security patches.
- Configure Windows Update to automatically download and install the latest Windows updates.
• **Very Important:** If you create a default_admin.asp page for your IMS site, **make sure** to change access permissions on it so that ordinary Internet browsers cannot use it. To do this, in Windows Explorer right click on the default_admin.asp file, choose Properties and choose the Security tab. Remove all entries for allowed user names except Administrator or whatever other login name you wish to allow access to the administration page. Apply the settings and press OK.

• Use an **Administrator** password that is called something other than "Administrator". Brute-force password cracking attacks have half the problem solved if they can assume there is a login called "Administrator" to attack.

• Use a seriously long (over 16 digits), randomly constructed password to make it difficult for brute-force password cracking assaults to guess your password.

• Install any supplemental security patches published by Microsoft after the last Windows Service Pack. Microsoft now has tools that can scan your system to determine if there are security patches published that have not yet been installed. Visit Microsoft TechNet at [http://www.microsoft.com/technet/default.asp](http://www.microsoft.com/technet/default.asp) and drill down to their Security pages for information on the latest security tools and patches.

• Install anti-virus software. Keep your anti-virus software updated with regular downloads from your vendor.

• Install Microsoft URLScan (a free download from Microsoft TechNet) or similar tool. URLScan is an ISAPI filtering tool for IIS that rejects a wide variety of malformed URL requests before they can hit IIS. It was published by Microsoft in 2001 and is an absolutely essential tool to prevent many different types of Denial of Service attacks. No doubt the functions provided by URLScan will continue to be offered by Microsoft either as independent tools or built into IIS. Manifold IMS works perfectly with URLScan.

• Apply Microsoft's IIS Lockdown Tool (a free download from Microsoft TechNet), or its successors, using Advanced Lockdown. Uncheck the box that disables support for Active Server Pages (.asp) and otherwise accept all of the defaults suggested by Advanced Lockdown. Manifold IMS works perfectly with Advanced Lockdown settings so long as Active Server Pages are still enabled. This tool is also very easy to use. Some recent editions of IIS may be shipped by Microsoft in lockdown mode by default.

• Do not run unnecessary services. If your server runs a web site only, do not install or enable additional services such as FTP, NNTP or others. If such services are already installed, use Internet Services Manager to stop them. Do not install any accessory software or Windows components that are not required.

• Do not install unnecessary applications on your web server. Every application you install increases the **attack surface** that an adversary can exploit. For example, don't install things like Microsoft Office on a machine that will only be a web server.

• Do not use your web server, ever, for Internet browsing or other applications. Some people press into use as a web server an otherwise underutilized machine that is occasionally used (out of boredom while waiting for some administrative task to complete, etc.) to browse the web or for other purposes. Dedicate a machine to web serving and don't use it for other purposes.

• Do not connect your web server on a local area network to other machines unless you really know what you are doing with security. It is safest to keep it isolated and to use a USB drive to exchange files with other machines.

• If you use Remote Desktop to work with your server, change the port it uses to some port other than the default. (Don't forget to leave this port open in your firewall.)

• Learn to use Advanced TCP/IP settings for the Internet Protocol in Network properties for the network card in use. If your web site is intended only for specific machines (such as those on an Intranet), use IP security to deny access to any unauthorized machines (IP addresses). If you are connected to Internet, use TCP/IP filtering to permit only those TCP ports absolutely required to service your web site (typically, port 80 for HTTP and port 443 for HTTPS). Strict IP filtering will not allow services such as DNS (used if you are browsing from the web server) so a truly secure regime will limit utilization of the system to a web serving only.

• Install a firewall such as Windows Firewall and learn to use it. Use a hardware firewall and/or software solution such as Microsoft's Internet Security and Acceleration Server. Hardware firewalls now cost well under $100. Configure your hardware firewall so that only those ports required for serving web pages are enabled, with all other ports disabled.

• Install the latest updates for Manifold System from [manifold.net](http://www.manifold.net).

• Get a good book on Windows and IIS security. Read it carefully and apply the recommendations. Surf the web and read the many free resources on Windows and IIS security.

• Participate in Manifold-L (email discussion list format) and the Georeference [Forum at http://forum.manifold.net](http://forum.manifold.net) for Manifold System users. Ask questions of your more experienced colleagues and as you gain expertise yourself give back to the community by assisting newbies with security questions.

**Very important:** Although Manifold IMS can work with Microsoft security tools for IIS such as URLScan and the IIS Lockdown Tool, it is possible that other IIS applications installed on your system cannot work with these tools or require modifications to the default settings of these tools. It is critically important to read the documentation for these security tools.
Minimizing Per-User Temp Files

When using a High isolation level in IIS, a new process will be created for each user accessing IMS. When this is done the multiple instances of IMS can not share data with each other and will be forced to create a separate set of temporary files for each user. This provides high isolation but results in a large number of temporary files in the system TEMP folder.

One way of reducing the number of temporary files created is to lower the isolation level applied to the web application that uses IMS so that multiple instances of IMS can operate in the same process. This does create a risk in that a crash of one instance of IMS will likely crash all other instances, but given that it is relatively difficult to crash IMS in the first place, this might be a good tradeoff in the case of well-debugged .asp files.

Troubleshooting

See the troubleshooting topic Problems with the Internet Map Server for detailed checklists of what might be wrong.

Note

You must be running Manifold System Professional Edition or greater to have the capabilities discussed in this topic. All Manifold editions except Personal Edition include the map server. If you are running Manifold System Personal Edition you will not have the capabilities discussed in this topic.

Customization

Manifold may be customized to present user-specified choices in various dialogs, such as palettes and the projection dialog. Custom options are made available by adding .xml files to the Config folder within the main Manifold installation directory (located at C:\Program Files\Manifold System\Config by default).

In Windows 2000, Windows XP and later Windows operating systems, ordinary user accounts do not have permissions to modify files within the Program Files folder. If we are working in such systems we can still use the customization features of Manifold by altering the Config file location in Tools - Options - File Locations to a folder where we have write permissions.

Customization options allow customization of Manifold installations in many areas, to name a few of the most common examples:

- Custom point styles taken from True Type fonts installed on the system.
- Custom scalable styles for points, lines areas and labels.
- Custom palettes and themes are used to color drawings or surfaces.
- Custom units of measure
- Custom ellipsoids
- Custom datums

Custom datum grids for NTv2
- Custom coordinate system (projection) presets
- Custom layout templates for use with print layouts.
- Command filters are XML files that specify which commands in the Manifold menu structure are enabled or disabled. Add-Ins that add commands to Manifold through scripts and configure toolbars.
- Scripts may invoke and control user interface elements such as dialogs. See the User Interface Scripting topic.
- Customized Geocoding Data Extensions providing additional geocoding data sources.
- Customized Manifold Geocoding Servers using the Geocoding Server Interface to connect to web-based or other geocoding data servers.
- Customized Manifold Image Servers using the Image Server Interface to connect to web-based or other image sources.
- Manifold may be programmed in a variety of ways using scripting languages, SQL, web programming or custom applications written in popular programming languages: See the Programming Manifold topic.

Many customization features use XML to specify additions. See the topics above for detailed on XML syntax and rules. In general, the following rules apply:

- XML (extended markup language) is used to specify both original factory settings and any options.
- All .xml files located in the Config directory and all subdirectories thereof will be read by Manifold upon startup. Any valid specifications found in such files will be used.
- Manifold's own "factory" settings are stored within the system itself. The factory settings may be overridden by providing .xml files that use the same names as the factory entities, if the Override system data with custom config files option is turned on (it is off by default) in the Miscellaneous page in Tools - Options.
- DO NOT CHANGE the factory settings unless you are truly expert in Manifold and are ready to work without technical support from manifold.net.
- When creating custom .xml specifications, the name of each custom item must be unique. Manifold keeps track of each customizable item by its name.
- After adding any new XML specifications, restart Manifold so they are loaded and available in the system.
- It makes sense to organize any custom additions into separate .xml files, one for palettes that are added, another for units of measure and so on. However, Manifold will parse all the .xml files found in the Config directory for valid attributes of any type in each of the files. One could therefore create a single .xml file, perhaps called MyCustomizations.xml, in which all customizations such as additional palettes, units of measure, custom ellipsoids, custom datums and a few custom projection presets are all kept.
Manifold® System Release 8.00 User Manual

- If you have added any custom specifications in your .map files, you are responsible to make sure that the .xml files providing those custom specifications are installed on every machine on which those custom specifications will be used.
- If you have purchased a technical support product from Manifold, support for customization requires developer level support.
- A simple check against elementary mistakes is to double-click open an .xml file to view it in Internet Explorer. If it is reasonably correct, IE will be able to open it and to show the contents in text form.

When a custom specification (such as a palette) is used within a particular component, the information for that custom specification will be saved with the component so the component will display properly. However, if the required .xml is not present on the system on which the .map file is used, the specification will not be available for any further usage.

**Editing .xml Files**

.xml files may be edited with Notepad. They are simply ASCII text files containing XML tags (called attributes) similar to those found in ordinary HTML pages used on the web. For example, a file called MyAltitudes.xml might contain:

```xml
<xml>
<palette>
    <name>My Altitude Palette</name>
    <colors>
        <color>#ebeaba</color>
        <color>#e4e5a0</color>
        <color>#faebbe</color>
        <color>#fee2a8</color>
        <color>#ffc882</color>
    </colors>
</palette>
</xml>
```

The above specifies a simple palette of five colors. In addition to Notepad, some users may prefer to use an XML editor such as Microsoft's XML Notepad editor.

**Predefined Items**

Manifold includes "intrinsic" definitions for quantities that are used to define others. These root definitions are compiled into the product and do not appear in any .xml files. They are written below as they would appear if they were defined in XML:

```xml
<unit>
    <name>meter</name>
    <nick>m</nick>
    <nickArea>sq m</nickArea>
    <scale>1</scale>
</unit>

<unit>
    <name>degree</name>
    <nick>deg</nick>
    <nickArea>sq deg</nickArea>
    <scale>1</scale>
    <latLon>True</latLon>
</unit>

<ellipsoid>
    <name>WGS 84</name>
```
Customization

Also included are presets for "plain" coordinate systems such as for Latitude / Longitude, Orthographic and others with default parameters.

Hexadecimal Numbers

Numbers written in hexadecimal form are written in a base 16 number system. Some XML customization attributes in Manifold, such as those used for point styles taken from a True Type font, can use hexadecimal numbers as an alternative to decimal numbers. Some attributes, such as the <color> attribute in palettes require the use of hexadecimal numbers.

Hexadecimal numbering uses the digits 1 through F to represent the numbers 1 through 15. One counts from 0 to 255 in hexadecimal using the sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, A, B, C, D, E, F, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 1A, 1B, 1C, 1D, 1E, 1F, 20, 21, ..., E9, EA, EB, EC, ED, EE, EF, F1, F2, F3, F4, F5, F6, F7, F8, F9, FA, FB, FC, FD, FE, FF.

Hexadecimal numbers are convenient for use with numbers in computers because each digit can represent a full byte. Thus, two-byte quantities such as the integer numbers from 0 to 255 can be represented with two-digit hexadecimal numbers from 00 to FF. Thus when one sees a number such as 04A3FFCE one knows exactly the values of each byte that composes this eight-byte, 64-bit number. Hexadecimal numbers are widely used in the specification of RGB color values.

Since a hexadecimal number like "22" can appear to be a decimal numbers, hexadecimal numbers are normally prefixed with a "#" symbol when used in Manifold .xml specifications.

Tech Tip

Manifold cannot use any customizations if the .xml files do not contain XML that is exactly correct. A useful test before launching Manifold is to open any newly created or modified .xml file in Internet Explorer. Internet Explorer will show a correct .xml file in a simple text format. If Internet Explorer cannot parse the .xml file, Manifold won't be able to either.
Custom Point Styles

Manifold can use point styles from four different sources:

- Point styles that are built into Manifold.
- Point styles that are created from True Type fonts installed in Windows.
- Point styles created from image files.
- Point styles created from custom scalable styles.

This topic discusses the first three methods of customizing point styles. For use of custom scalable styles see the Custom Scalable Styles for Points, Lines, Areas and Labels topic.

Point styles that are created from True Type fonts or images are loaded into Manifold based upon directions specified within .xml files found in the Config folder. When Manifold launches it reads any .xml files that are placed in the Config folder and then opens True Type fonts or image files they mention to create new point styles. If an .xml file mentions a True Type font or image file that is not available in the Windows system, the point style thus specified will not be available and will be displayed as the default circle point style.

For example, an .xml file adding all characters in the particular font could be provided to customize the Manifold installation. This .xml file tells Manifold to create point styles based on the characters in the given font. If for some reason the specified font is not installed in Windows, the point styles created from this .xml file will not be available.

Point Styles Created from Fonts

Point styles created from True Type fonts may be used just like any point style, except that they are always created using the foreground color only. Users can add their own point styles from True Type fonts by installing a desired True Type font and then creating an .xml file in the following pattern:

<xml>
<style>
  <name>Name for this style</name>
  <font>Windows font name</font>
  <symbol>64</symbol>
  <type>point</type>
</style>
</xml>

Rules

- There can be any number of <style> ... </style> entries within a single XML file between the <xml> tag at the beginning of the file and the </xml> tag at the end of the file.
- The name string supplied in the <name> attribute is mandatory and must be unique. Many users will construct a unique name by appending the symbol number to the name of the font.
- The font name string supplied in the <font> attribute is mandatory and must be one of the font names installed in Windows.
- The number in the <symbol> attribute is mandatory and must be a number that corresponds to a valid character, either in decimal notation or in hexadecimal (hexadecimal numbers must be preceded by a # character).
- The value in the <type> attribute is mandatory and must be "point".

Place the new or modified .xml file containing the point styles into the Config folder for Manifold (normally C:\Program Files\Manifold System Professional\Config) and restart Manifold. When Manifold launches, the system will scan all .xml files in the Config folder. Any <style> ... </style> entries of <type> "point" found in any of those .xml files that correspond to characters in installed Windows fonts will be loaded into the system as an available point style.

Example
We’ve installed the Microsoft Webdings font in our Windows system. We then created a file in the Config folder called PointsWebdings.xml that contains:

```xml
<xml>
  <style>
    <name>Webdings #2A</name>
    <font>Webdings</font>
    <symbol>#2A</symbol>
    <type>point</type>
  </style>
  <style>
    <name>Webdings #2B</name>
    <font>Webdings</font>
    <symbol>#2B</symbol>
    <type>point</type>
  </style>
</xml>
```

This file uses hexadecimal notation for the character numbers, the same as used in the Windows Character Map utility program. It installs two point styles from the Webdings font.

When Manifold launches it will see the PointsWebdings.xml file in the Config folder and will read it to see what it contains. It will find two point styles in the file and will load them for use. The two styles used may be seen below:

The Webdings font is available for free download from Microsoft’s typography page at

This high quality font includes numerous symbols that will be useful as point styles in GIS applications.

**Decimal notation**

If desired we can write the above example using decimal numbers for the <symbol> values as:

```xml
<xml>
  <style>
    <name>Webdings 042</name>
    <font>Webdings</font>
    <symbol>42</symbol>
    <type>point</type>
  </style>
  <style>
    <name>Webdings 043</name>
    <font>Webdings</font>
    <symbol>43</symbol>
    <type>point</type>
  </style>
</xml>
```
This example is equivalent to the hexadecimal form since decimal 42 is the same as hexadecimal 2A and decimal 43 is the same as hexadecimal 2B. Note that the <name> specified for each style is the font followed by the character number in decimal or hexadecimal. We can name the style however we choose; however, most users soon tire of creating inventive names for different point styles and eventually will adopt a standard naming scheme like the one used above.

Using individual characters or entire fonts

Manifold’s .xml specification for point styles allows individual characters to be used from installed Windows fonts. It is often the case that only a few symbols in a font are useful to us in GIS, so the ability to specify only selected characters prevents the formatting menus from being overwhelmed by many styles that are not useful.

At times we might wish to simply use an entire font. It would be tedious to specify each of 255 styles by hand. A much faster method is to use the PointsWingdings.xml file provided as an example on the Manifold downloads site. Suppose we want to use all of the characters in a font called NatoSymbols that has been installed as a Windows font in our system.

We would proceed as follows:

To exploit PointsWingdings.xml as a template:

1. Copy PointsWingdings.xml and paste it as PointsNatoSymbols.xml
2. Open PointsNatoSymbols.xml with Notepad [Right click on the file and choose Open With… Notepad].
3. Replace "Wingdings" with "NatoSymbols" throughout the file.
4. Save the file

Since the original file listed all of the characters using a standard naming scheme, doing a search and replace using the new font name will create a new file for the NatoSymbols font.

Using a previously created .xml file as a template to create a new file for a different font is very fast. Even if we wish to only use a few characters out of a font it is usually faster to first use a template to create an .xml file that includes all of the characters as styles and to then delete those styles that are not wanted. Since few fonts with interesting symbols have all available slots full of characters it usually will be necessary to delete some of the point styles created by simply using a “full” font template like PointsWingdings.xml.

A reminder: point styles cannot be created from a font unless it is installed in the system. Use the Fonts selection in the Windows Control Panel to see fonts that are installed in your system.

Point Styles Created from Images

Point styles created from images may be used just like any point style, except that they are not resizable (and so may result in unexpected scaling effects when size on the monitor or on printed pages is compared) and do not use either foreground or background formatting colors. In addition, point styles created from images will not be shown in selection color when selected.

Users can add their own point styles from images by installing a desired image file (one image per file) and then creating an .xml file in the following pattern:

<xml>
<style>
  <name>Name for this style</name>
  <file>images\filename.png</file>
  <type>point</type>
</style>
</xml>
Customization

**Rules**

- There can be any number of `<style>` entries within a single XML file between the `<xml>` tag at the beginning of the file and the `</xml>` tag at the end of the file.
- The name string supplied in the `<name>` attribute is mandatory and must be unique.
- The path string in the `<file>` attribute is mandatory. It specifies the path to the image file from the configuration directory. In the pattern shown above a `filename.png` image file must be within an `images` directory that is in the `Config` directory.
- Image files may be in any of the following formats: BMP, GIF, JPG, PNG, TIFF, EXIF, WMF and EMF. Each image file contains one image, corresponding to one point style.
- The value in the `<type>` attribute is mandatory and must be "point".

Place the new or modified `.xml` file containing the image point style specifications into the `Config` folder for Manifold (normally `C:\Program Files\Manifold System Professional\Config`) and restart Manifold. When Manifold launches, the system will scan all `.xml` files in the `Config` folder. Any `<style>` entries of `<type>"point"` found in any of those `.xml` files that correspond to image files will be loaded as a new point style.

Images can contain pixels in transparent color. `.png` format is a good format to use to save images that contain invisible pixels (transparent color). `.png` is fast and efficient and a good choice overall for iconic images.

Point styles created from images will be centered in the center of the image. Point styles created from images are not resizable, since they use a fixed pattern of pixels.

**Example**

Suppose we create an `images` subdirectory in the `Config` folder. We place several image files in `.png` format in that folder. We create a `PointImages.xml` file in the `Config` folder that contains:

```xml
<xml>
  <style>
    <name>Manifold Icon</name>
    <file>images\mfd_icon.png</file>
    <type>point</type>
  </style>
  <style>
    <name>Blue Pin</name>
    <file>images\blue_pin.png</file>
    <type>point</type>
  </style>
  <style>
    <name>Purple Pin</name>
    <file>images\purple_pin.png</file>
    <type>point</type>
  </style>
  <style>
    <name>Red Pin</name>
    <file>images\Red_pin.png</file>
    <type>point</type>
  </style>
  <style>
    <name>Orange Pin</name>
    <file>images\orange_pin.png</file>
    <type>point</type>
  </style>
</xml>
```
The above XML adds point styles consisting of a Manifold logo style and a collection of pushpin images in various colors. The *mfd_icon.png* image looks like:

![mfd_icon.png](images\mfd_icon.png)

The *orange_pin.png* image looks like:

![orange_pin.png](images\orange_pin.png)

The illustrations above were created by importing each *.png* file as an image and then opening the image in an image window with the background layer turned off in the layers pane and the border layer turned on. The border shows the extent of the image, which would otherwise be difficult to see since both images use invisible pixels. Note that the *orange_pin.png* image consists mostly of invisible pixels. The other color pin images were created from the orange image by using hue / saturation to change the hue and then exporting the altered image to a *.png* file.

The two point styles above can be used to show how point styles using images are centered at the point location. To illustrate center positioning we've created a map of Europe that has a drawing layer with major cities as points. We have two copies of the cities layer in our map. One layer is formatted to use a small circle for each point. The other layer uses either the Manifold logo point style or the orange pin style.
When we use the Manifold logo point style we can see from the positions of the small white circle (from the other
cities layer) that the logo is centered on each city point. We can also see that it is a challenge to design iconic
images that work equally well when superimposed on any color background. The Manifold logo, for example,
uses a splash of yellow color that disappears in lightly colored backgrounds.

When we use the orange pin point style we see that the image is also centered on each point; however, because
the image consists mostly of invisible pixels the center of the image falls visually at the point of the "pin". This
provides a nice effect as if the pin is pushed into the map at the point we wish to mark.

Tech Tips

Manifold cannot use any customizations if the .xml files do not contain XML that is exactly correct. A useful test
before launching Manifold is to open any newly created or modified .xml file in Internet Explorer. Internet
Explorer will show a correct .xml file in a simple text format. If Internet Explorer cannot parse the .xml file,
Manifold won't be able to either.

To review fonts use the Character Map utility that is available in most Windows systems. From the Start button
choose Programs - Accessories - System Tools - Character Map. (Also available from a Windows Command
Prompt (DOS) window as charmap.exe). The Character Map utility will show the name of each font installed in
your system. Clicking on any character will display it and will show the character code (number) in hexadecimal in
status bar in the lower left corner of the Character Map window. A Character Map code of 0x6C is the same as
#6C, the "0x" prefix being another way, like the "#" prefix, of indicating the number is given in hexadecimal.

XML files read by Manifold from the Config directory can contain specifications for any mixture of customizable
entities. For example, a single file can contain point styles, palettes, a new unit of measure and so on. It is
usually easier to keep track of things if customizations are organized into separate files by what is being
customized.

Choose image-based point styles with care if maps will be printed, since the literal printing of most point style
images at the pixel resolutions typical of many printers will result in very small, almost invisible point symbols. To
print more visible point styles, import the image into Manifold and use resize to increase the size of the image,
export the image and then use that image in the point style. This may result in very large point styles on screen
but will allow printing as desired.

The examples above place images in a subdirectory called images within the Config directory. The images can
be wherever desired within the Config directory; however, keeping them neatly organized within subdirectories is
a good idea if many images will be used.
The "embossed" look of the countries in Europe was created by first making boundary lines for each area and then copying the boundary lines into a second layer. The boundary lines in the lower layer were formatted with a size of 2 and given a foreground color lighter than the areas. The boundary lines in the upper layer were formatted with a size of 1 and given a foreground color darker than the areas. This layer was then repositioned slightly with CTRL-grabber to the Northwest.

A "raised border" effect can be created by reversing the sizes and colors of the boundary lines in the two layers. If the upper (shifted) layer is the lighter, thicker layer and the lower line layer is the thinner, darker layer the perceptual effect is one of raised borders as seen above.

New releases of Manifold may introduce new formatting styles. The /slist command line option provides a handy way for programmers to get a comprehensive list of all area, label, line and point styles available and their names.
Custom Scalable Styles for Points, Lines, Areas and Labels

Manifold allows definition of scalable custom styles for points, lines, areas and labels. Scalable styles are defined using XML files that contain one or more style definitions. Style definitions are built up from a repertoire of vector painting commands.

A custom style is defined using a `<style>` tag. A scalable custom style must also have a `<code>` tag with an optional `autosize` attribute and one or more painting commands.

Scalable styles are defined by .xml files in the following pattern:

```xml
<xml>
  <style>
    <name>MyName</name>
    <type>point</type>
    <preview>8</preview>
    <code>
      (painting commands go here)
    </code>
  </style>
</xml>
```

A custom line style is created by defining the metric of a line segment with an X extent of -1000 to 1000, which is then repeated along the line.

Rules

There can be any number of `<style>` ... `<style>` entries within a single XML file between the `<xml>` tag at the beginning of the file and the </xml> tag at the end of the file. Within `<style>` entries the following attributes are used:

- `<name>` is mandatory and must be unique.
- `<type>` is mandatory and must be `area`, `label`, `line` or `point`, specifying what type of style this is.
- `<preview>` is optional and specifies the preview size of the style, in points.
- `<code>` is mandatory. It contains one or more painting commands that describe how the style is drawn ("painted"). It may contain an optional `autosize` attribute and one or more painting commands.
- There can one or more painting commands entries within a `<code>` entry.

Painting Commands

Painting commands that may be used within the `<code>` tag are:

- `<arc xmin=... ymin=... xmax=... ymax=... beg=... end=... fore=... />` - The `<arc>` tag paints an arc between the given "beg" and "end" angles. The angles are measured in degrees and can be fractional.
- `<dash size=... backP=... foreD=... backD=... fore=... back=.../>` - The `<dash>` tag paints a dashed line of given size. The size attribute defines the relative size of the object painted by the tag with respect to the size of the line object (1000 is the same size, 500 is half the size of the line object, etc). The backP attribute defines the length of the first dash, painted with background color, in 1/1000th of the size of the line object. The foreD attribute defines the length of the second dash, painted with foreground color. The backD attribute defines the length of the third dash, painted with background color. The summary length of the dashes painted with each color must be positive. The length of each dash must be non-negative.
- `<ellipse xmin=... ymin=... xmax=... ymax=... fore=... back=... />` - The `<ellipse>` tag paints an ellipse.
- `<polygon fore=... back=...> <point x=... y=... /> ... </polygon>` - The `<polygon>` tag paints a polygon. Each `<polygon>` tag should contain three or more `<point>` tags.
- The `<polyline>` tag paints a polyline. Each `<polyline>` tag should contain two or more `<point>` tags.

- The `<rectangle>` tag paints a rectangle.

- The `<refLine>` tag paints a line object of given size and style. The size attribute defines the relative size of the object painted by the tag with respect to the size of the line object (1000 is the same size, 500 is half the size of the line object, etc). The style attribute must contain the name of an already defined line style.

- The `<refPoint>` tag paints a point object of given size and style. The style attribute of the `<refPoint>` tag must contain the name of an already defined point style. The `angle` attribute gives the rotation angle of the point symbol in degrees (clockwise rotation).

- The `<text>` tag paints the text of the context label object with given style. The `style` attribute of the `<text>` tag can be any of the following values, which correspond to Manifold label styles: `box`, `boxB`, `boxCorners`, `boxFrame`, `boxGradHorzDD`, `boxGradHorzDL`, `boxGradHorzLL`, `boxGradVertDD`, `boxGradVertDL`, `boxGradVertLL`, `boxInner`, `boxL`, `boxR`, `boxT`, `boxThick`, `boxThickB`, `boxThickL`, `boxThickR`, `boxThickT`, `halo`, `haloLB`, `haloLT`, `haloRB`, `haloRT`, `haloWide`, `plain`.

All attributes are required except the `back` and `fore` attributes for all tags and the `border` and `style` attributes in the `<text>` tag. The possible values of the `back`, `border` and `fore` attributes are `b` (background color), `f` (foreground color), `m` (a mix between the background color and the foreground color), `n` (transparent color), or an absolute color value (such as `#00ff00` or `0:255:0`).

See the Custom Palettes and Themes topic for notations that may be used to specify absolute color value in either hexadecimal or decimal form.

By default, a style is defined for an object with a size of 1 (1 printer's point). If the `autosize` attribute in the `<code>` tag is set to `true` (the default), the system scales the output of painting commands so that a box of (X: -1000...1000, Y: -1000...1000) corresponds to the box used by the built-in symbol of the same size. If the `autosize` attribute is set to `false`, the system scales the output of the painting commands so that 1000 X or Y units equal X physical points, where X is the size of the object being painted.

**Examples**

**A custom point style:**

```xml
<xml>
  <style>
    <name>customFlag</name>
    <type>point</type>
    <code>
      <polygon>
        <point x="0" y="500" />
        <point x="1000" y="750" />
        <point x="0" y="1000" />
      </polygon>
    </code>
  </style>

  <style>
    <name>customFlagWithDot</name>
    <type>point</type>
    <code>
      <ellipse xmin="-200" ymin="-200" xmax="200" ymax="200" back="m" />
      <refPoint x="0" y="0" size="1000" style="customFlag" />
    </code>
  </style>
</xml>
```
A custom line style:

```xml
<xml>
<style>
  <name>Custom1</name>
  <type>line</type>
  <preview>8</preview>
  <code>
    <polyline>
      <point x="0" y="0"/>
      <point x="0" y="400"/>
    </polyline>
    <polyline>
      <point x="0" y="0"/>
      <point x="200" y="0"/>
      <point x="200" y="200"/>
    </polyline>
    <polyline>
      <point x="200" y="0"/>
      <point x="400" y="0"/>
      <point x="400" y="200"/>
    </polyline>
    <polyline>
      <point x="400" y="0"/>
      <point x="600" y="0"/>
      <point x="600" y="200"/>
    </polyline>
    <polyline>
      <point x="600" y="0"/>
      <point x="800" y="0"/>
      <point x="800" y="200"/>
    </polyline>
    <polyline>
      <point x="800" y="0"/>
      <point x="1000" y="0"/>
      <point x="1000" y="200"/>
    </polyline>
  </code>
</style>
<style>
  <name>Custom2</name>
  <type>line</type>
  <preview>8</preview>
  <code>
    <refLine style="Custom1" size="1000"/>
    <ellipse xmin="-100" ymin="-300" xmax="100" ymax="-100"/>
  </code>
</style>
</xml>
```
A custom area style:

```xml
<xml>
  <style>
    <name>Weird Hatch</name>
    <type>area</type>
    <code>
      <polyline>
        <point x="-1000" y="0" />
        <point x="800" y="600" />
        <point x="-500" y="900" />
        <point x="1000" y="0" />
      </polyline>
    </code>
  </style>
</xml>
```

**Tech Tip**

Each built-in style for areas, labels, lines and points has been assigned a name, for use in custom styles. For a complete list of names, see the manifold.net web site within the Support pages hierarchy.

Customization

Custom Point Styles
Custom Palettes and Themes

Manifold has two systems to allow specification of custom formatting characteristics such as color in thematic formatting. One system, using custom palettes, is a legacy system that can be used to specify only colors. The more general method is to use custom themes, which can specify many different formatting characteristics such as rotation angles, color, and the size and style of labels, areas, lines or points.

Because custom palettes may not be supported at some time in the future, users should take care to employ only custom themes. The information in this topic on custom palettes is provided for backward compatibility with earlier versions of Manifold.

Note: in this topic, the word “theme” is used to mean a collection of formatting characteristics used with values for thematic formatting. It is a different use of the same word that is also used to mean a theme component.

In both cases, either custom palettes or themes used for thematic formatting of drawings and surfaces or terrains are loaded from .xml files found in the Config folder. Specifications for custom palettes or themes are enclosed within <palette> … </palette> tags for a custom palette or <theme> … </theme> tags to specify a custom theme.

If an .xml file specifying a custom theme occurs in the Config folder Manifold will automatically load it upon startup. If the .xml file specifying the custom theme neglects to provide a name for the theme, Manifold will name the theme Custom X, where X is a number that makes the name unique, for example, Custom 1, Custom 2 and so on.

Custom Palettes

Manifold palettes come in two forms: relative palettes in which colors only are specified, and fixed palettes that also specify values for the intervals to which colors apply. In relative palettes, only a list of colors need be specified. In fixed palettes, a list of colors as well as a corresponding list of values must be specified.

Users can add their own palettes (including those with fixed values) by creating .xml files in the following patterns:

For relative palettes:

```xml
<xml>
<palette>
  <name>My Relative Palette</name>
  <colors>
    <color>#000000</color>
    <color>#ff0000</color>
    <color>#00ff00</color>
    <color>#0000ff</color>
    <color>#ffffff</color>
  </colors>
</palette>
</xml>
```

For fixed palettes:

```xml
<xml>
<palette>
  <name>My Fixed Palette</name>
  <colors>
    <color>#000000</color>
    <color>#ff0000</color>
    <color>#00ff00</color>
    <color>#0000ff</color>
    <color>#ffffff</color>
  </colors>
</palette>
</xml>
```
Either fixed or relative palettes may also use decimal numbers to specify RGB color values as well as hex numbers:

```xml
<xml>
<palette>
  <name>Sample palette</name>
  <colors>
    <color>0</color>
    <color>255:0:0</color>
    <color>0:255:0</color>
    <color>0:0:255</color>
    <color>65280</color>
    <color>#000000</color>
  </colors>
</palette>
</xml>
```

The example above decimal numbers with the last color specified using hexadecimal. Decimal and hexadecimal color specifications may be used within the same palette.

### Rules for Palettes

- There can be any number of `<palette>` ... `<palette>` entries within a single XML file between the `<xml>` tag at the beginning of the file and the `</xml>` tag at the end of the file.
- The name string in the `<name>` attribute is mandatory and must be unique.
- Values of colors are specified in the `<color>` attribute in either hexadecimal form or decimal form.
- Hexadecimal colors are in "#rrggbb" form where rr, gg and bb are pairs of hexadecimal digits giving a hexadecimal number corresponding to the decimal number range from 0 to 255 for Red (rr), Green (gg) or Blue (bb). Leading zeros are significant, so that RGB values of 3, 5 and 6 are coded as 00003 in hexadecimal numbers. The examples above show a list of colors that are black, pure red, pure green, pure blue and white.
- Decimal colors may be in two forms: either r:g:b form where r, g and b are decimal integer numbers in the range from 0 to 255 or as a single decimal number that is the decimal equivalent of a #rrggbb hexadecimal number.
- There must be at least two colors listed in a palette.
- Fixed palettes must also include a list of values in the `<values>` attributes.
- Values in the `<value>` attributes are floating-point numbers. Negative numbers are prefixed with a - minus sign.
- Values must be listed in ascending order from lowest to highest value. Each value must be unique within the list for that palette. The number of values must be exactly the same as the number of colors in that palette.

### Custom Themes
Users can add their own themes by creating .xml files in the following pattern:

```xml
<xml>
  <theme>
    <type>color</type>
    <interval>true</interval>
    <colors>
      <color>#333333</color>
      <color>#666666</color>
      <color>#999999</color>
      <color>#cccccc</color>
      <color>#ffffff</color>
    </colors>
    <colorMin>#000000</colorMin>
    <colorMax>#ffffff</colorMax>
    <colorDef>#000000</colorDef>
    <values>
      <value>-69.00</value>
      <value>-21.00</value>
      <value>27.00</value>
      <value>75.00</value>
      <value>123.00</value>
    </values>
  </theme>
</xml>
```

Themes use a more modern nomenclature than do palettes. Instead of referring to a "relative" or "fixed" palette, themes are called interval based (equivalent to relative palettes) or value based (equivalent to fixed palettes).

**Rules**

- The `<theme>` tag surrounds the definition of the theme. There can be any number of `<theme>` entries within a single XML file between the `<xml>` tag at the beginning of the file and the `</xml>` tag at the end of the file. However, only the first such tag is used. The others will be ignored.
- The `<type>` tag contains the type of the theme and can be equal to any of the following values: angle, color, areaSize, areaStyle, labelSize, labelStyle, lineSize, lineStyle, pointSize, or pointStyle.
- The `<interval>` tag determines whether the theme is interval-based (true) or value-based (false). Interval-based themes assign formatting to data falling within the specific intervals, and value-based themes assign formatting to data equal to specific values.
- The `<values>` and `<value>` tags contain interval breaks or unique values depending on whether the theme is interval-based or value-based. The theme must contain at least one value.
- The `<column>` tag contains the name of the column to use. This tag is optional.
- Tags specifying specific characteristics consist of a tag using the plural name of the given type followed by singular name tags for each specific case. The `<colors>` and `<color>` tags contain formatting data for colors as seen in the prototype XML above. A theme for line styles would use `<lineStyles>` and `<lineStyle>` tags, a theme for point styles would use `<pointStyles>` and `<pointStyle>` tags and so on. The number of `<color>` tags (or other singular tags) and `<value>` tags must be the same.
- The `<colorMin>` and `<colorMax>` tags are used with interval-based themes to format color and contain formatting data for values that are less than the lowest break, or greater than the highest break. An interval-based theme used to format line styles would use `<lineStyleMin>` and `<lineStyleMax>` tags and so on.
- The `<colorDef>` tag is used with value-based themes and contains formatting data to use for values that are different from any of defined unique values. A theme for line styles would use the `<lineStyleDef>` tag and so on.
- Values of colors are specified in the `<color>` attribute in either hexadecimal form or decimal form.
- Hexadecimal colors are in "#rrggbb" form where rr, gg and bb are pairs of hexadecimal digits giving a hexadecimal number corresponding to the decimal number range from 0 to 255 for Red (rr), Green (gg) or Blue (bb). Leading zeros are significant, so that RGB values of 3, 5 and 6 are coded as 030506 in...
hexadecimal numbers. The examples above show a list of colors that are black, pure red, pure green, pure blue and white.

- Decimal colors may be in two forms: either \texttt{r:g:b} form where \(r\), \(g\) and \(b\) are decimal integer numbers in the range from 0 to 255 or as a single decimal number that is the decimal equivalent of a \#rrggbb hexadecimal number.
- There must be at least two colors listed in a theme.
- Fixed themes must also include a list of values in the \texttt{<values>} attributes.
- Values in the \texttt{<value>} attributes are floating-point numbers. Negative numbers are prefixed with a - minus sign.
- Values must be listed in ascending order from lowest to highest value. Each value must be unique within the list for that theme. The number of values must be exactly the same as the number of colors in that theme.

**Theme Examples**

To create an example of a theme, use the Thematic Formatting dialog to create a format and then press the Save to File button to save it as an .xml file. Open the .xml file with Notepad to see how the .xml implements the above rules.

**Using Palettes or Themes**

To utilize newly created or modified palettes or themes place the new or modified .xml file containing the palettes into the Config folder for Manifold (normally C:\Program Files\Manifold System\Config) and restart Manifold.

To quickly check what palettes are currently available, see the Tools - Options, Color Palettes dialog.

When Manifold launches, the system will scan all .xml files in the Config folder. Any \texttt{<palette>} or \texttt{<theme>} entries found in any of those .xml files will be loaded into the system as available palettes.

**Color Specification in Hex or Decimal**

Most classic graphics programming is done specifying colors using hex numbers in the \#rrggbb pattern. However, most Windows programs used in graphics editing report RGB colors using triplets of decimal numbers. Manifold can accept both numeric representation styles.

The hex specifications:

\begin{verbatim}
<color>#000000</color>
<color>#ff0000</color>
<color>#00ff00</color>
<color>#0000ff</color>
\end{verbatim}

...define exactly the same colors as the decimal specifications:

\begin{verbatim}
<color>0:0:0</color>
<color>255:0:0</color>
<color>0:255:0</color>
<color>0:0:255</color>
\end{verbatim}

The third style, of reporting concatenated hex values (\#rrggbb) as their equivalent decimal number value is rarely used except as a shorthand way of specifying black color. The following pairs of values are equivalent:

\begin{verbatim}
<color>#000000</color>
<color>0</color>
<color>#ff0000</color>
<color>6711680</color>
\end{verbatim}
Example

We've created a file in the Config folder called mypalettes.xml that contains:

```xml
<xml>
<palette>
  <name>Atlas Colors in Meters</name>
  <colors>
    <color>#7897bb</color>
    <color>#84afcf</color>
    <color>#95c4dc</color>
    <color>#bfdbe3</color>
    <color>#e7eff1</color>
    <color>#b6d294</color>
    <color>#d5e3b9</color>
    <color>#f2dbb4</color>
    <color>#e7bf83</color>
    <color>#deac6b</color>
    <color>#ab8e59</color>
    <color>#e2ddd6</color>
    <color>#ebe7e2</color>
    <color>#f2f0ee</color>
    <color>#ffffff</color>
  </colors>
  <values>
    <value>-8000</value>
    <value>-6000</value>
    <value>-4000</value>
    <value>-2000</value>
    <value>-200</value>
    <value>0</value>
    <value>100</value>
    <value>200</value>
    <value>500</value>
    <value>1000</value>
    <value>2000</value>
    <value>3000</value>
    <value>4000</value>
    <value>5000</value>
    <value>6000</value>
  </values>
</palette>
<palette>
  <name>Atlas Colors in Feet</name>
</xml>
```
<colors>
  <color>#7897bb</color>
  <color>#84afcf</color>
  <color>#95c4dc</color>
  <color>#b6d294</color>
  <color>#d5e3b9</color>
  <color>#f2dbb4</color>
  <color>#e7bf83</color>
  <color>#deac6b</color>
  <color>#ab8e59</color>
  <color>#e2ddd6</color>
  <color>#ebe7e2</color>
  <color>#ff00ee</color>
  <color>#ffffff</color>
</colors>

/values>
  <value>-26248</value>
  <value>-19686</value>
  <value>-13124</value>
  <value>-6562</value>
  <value>-656</value>
  <value>0</value>
  <value>328</value>
  <value>656</value>
  <value>1640</value>
  <value>3281</value>
  <value>6562</value>
  <value>9843</value>
  <value>13124</value>
  <value>16409</value>
  <value>19686</value>
</values>
</palette>

<palette>
  <name>Atlas Colors</name>
  <colors>
    <color>#7897bb</color>
    <color>#84afcf</color>
    <color>#95c4dc</color>
    <color>#b6d294</color>
    <color>#d5e3b9</color>
    <color>#f2dbb4</color>
    <color>#e7bf83</color>
    <color>#deac6b</color>
    <color>#ab8e59</color>
    <color>#e2ddd6</color>
    <color>#ebe7e2</color>
    <color>#ff00ee</color>
    <color>#ffffff</color>
  </colors>
</palette>
When Manifold launches it will see the `mypalettes.xml` file in the `Config` folder and will read it to see what it contains. It will find three palettes in the file and will load them for use. Two of the palettes are fixed palettes while the third file is a relative palette. Note that negative numbers may be used as values for fixed palettes.

All three palettes use the same colors. The two fixed palettes have different values, which we can see upon examination are the same numbers that would be used for elevations either in feet or in meters. This is a fairly typical arrangement when creating a new palette intended for use with surfaces. Surfaces usually originate in either meter-based data sets, where the elevation values are given in meters, or in foot-based elevation values such as US SDTS DEMs where the elevations are in feet. It is convenient to have the same fixed palette available with both meter-based as well as foot-based palettes so that the color scheme can be used for the same elevation above or below sea level regardless of whether the numbers in the surface represent meters or feet.

It is also convenient to have a version of a fixed palette available as a relative palette. This is allows a quick look at how the full range of palette colors appears in use. We can use whatever data set we want and even if it only ranges between -100 and 1000 we will still see the full set of colors.

**Tech Tip**

Manifold cannot use any customizations if the `.xml` files do not contain XML that is exactly correct. A useful test before launching Manifold is to open any newly created or modified `.xml` file in Internet Explorer. Internet Explorer will show a correct `.xml` file in a simple text format. If Internet Explorer cannot parse the `.xml` file, Manifold won’t be able to either.
Custom Units of Measure

Manifold uses units of measure in a variety of places such as in the units box used with most projections. The definitions of units available to Manifold are compiled into the product. User-supplied definitions may be loaded from .xml files found in the Config folder. If desired, users can add their own units of measure to incorporate specialized, historical or local units of measure into Manifold.

Units are defined by .xml files in the following pattern:

```xml
<xml>
  <unit>
    <name>My Own Centimeter</name>
    <nick>my cm</nick>
    <nickArea>my sqcm</nickArea>
    <scale>0.01</scale>
  </unit>
  <unit>
    <name>Five-degree</name>
    <nick>fd</nick>
    <nickArea>my sqfd</nickArea>
    <scale>5.0</scale>
    <latLon>True</latLon>
  </unit>
</xml>
```

**Rules**

- There can be any number of `<unit>` entries within a single XML file between the `<xml>` tag at the beginning of the file and the `</xml>` tag at the end of the file.
- The name string supplied in the `<name>` attribute is mandatory and must be unique.
- The flag in the `<latLon>` attribute must be set to "True" for angular measurement units such as degrees or radians and set to "False" or omitted for ordinary measurement units.
- The value in the `<scale>` attribute is the size of the unit relative to a degree (if the latLon flag is True) or a meter (if the latLon flag is False).
- `<nick>` and `<nickArea>` names are nicknames (abbreviations) of the units of measure that will be used by Manifold in various readouts. The `<nickArea>` name is used for the areal unit of measure, such as square meters.

To utilize newly created or modified units place the new or modified .xml file containing the units into the Config folder for Manifold (normally C:\Program Files\Manifold System Professional\Config) and restart Manifold.

When Manifold launches, the system will scan all .xml files in the Config folder. Any `<unit>` entries found in any of those .xml files will be loaded into the system as available units.

**Example**

We've created a file in the Config folder called myunits.xml that contains units we would like to use with Manifold. We find it annoying that English units like feet are derived from the physical dimensions of an English king's body parts, so we will create new units based on our own body parts. We also find working in units of five degrees more convenient than just one degree at a time so we will create a new angular unit that is equivalent to five degrees:

```xml
<xml>
  <unit>
    <name>Thumb</name>
    <nick>thb</nick>
    <nickArea>sq thb</nickArea>
  </unit>
</xml>
```
When Manifold launches it will see the myunits.xml file in the Config folder and will read it to see what it contains. It will find definitions for three new units of measure the file and will load them for use. Two of the units are linear measures defined from meters while the third is an angular measurement based on degrees.

One Thumb is equivalent to 0.05 meters, or five centimeters. One Arm is equivalent to 50 centimeters. Note that both of these units of measures are linear measures since the latLon attribute is not present in them.

The definition for ArcHand says it is equivalent to five degrees. We have decided to call our unit an "ArcHand" because a hand has five fingers just like this unit represents five degrees. When reported on the status bar in drawings projected using ArcHands the abbreviation will be ah or sq ah.

**Tech Tip**

Manifold cannot use any customizations if the .xml files do not contain XML that is exactly correct. A useful test before launching Manifold is to open any newly created or modified .xml file in Internet Explorer. Internet Explorer will show a correct .xml file in a simple text format. If Internet Explorer cannot parse the .xml file, Manifold won't be able to either.
Custom Ellipsoids

Manifold uses ellipsoids in projection calculations. See the The Earth as an Ellipsoid for more information. The definitions of ellipsoids available to Manifold are compiled into the product. User-supplied definitions may be loaded from .xml files found in the Config folder. If desired, users can add their own ellipsoids to incorporate specialized, historical or local ellipsoids into Manifold.

Ellipsoids are defined by .xml files in the following pattern:

<xml>
    <ellipsoid>
        <name>My Ellipsoid</name>
        <majorAxis>6377563</majorAxis>
        <invFlattening>299</invFlattening>
    </ellipsoid>
</xml>

Rules

- There can be any number of <ellipsoid> ... </ellipsoid> entries within a single XML file between the <xml> tag at the beginning of the file and the </xml> tag at the end of the file.
- The name string supplied in the <name> attribute is mandatory and must be unique.
- <majorAxis> is mandatory and is the length of the major axis in meters.
- <invFlattening> is the value of the inverse flattening. The <invFlattening> attribute may be replaced with by the <eccentricity> attribute specifying the eccentricity of the ellipsoid, or by the <minorAxis> attribute giving the length of the minor axis in meters. A value for the minor axis that is greater than the major axis will be rejected.

To utilize newly created or modified ellipsoids place the new or modified .xml file containing the ellipsoids into the Config folder for Manifold (normally \C:\Program Files\Manifold System Professional\Config) and restart Manifold.

When Manifold launches, the system will scan all .xml files in the Config folder. Any <ellipsoid> ... </ellipsoid> entries found in any of those .xml files will be loaded into the system as available ellipsoids.

Example

We've created a file in the Config folder called myellipsoids.xml that contains ellipsoids we would like to use with Manifold. These ellipsoids will help us create maps of the Moon and Mars:

<xml>
    <ellipsoid>
        <name>Moon</name>
        <majorAxis>1738000</majorAxis>
        <eccentricity>0.058730</eccentricity>
    </ellipsoid>
    <ellipsoid>
        <name>Mars</name>
        <majorAxis>3388000</majorAxis>
        <minorAxis>3388000</minorAxis>
    </ellipsoid>
</xml>

When Manifold launches it will see the myellipsoids.xml file in the Config folder and will read it to see what it contains. It will find definitions for ellipsoids named Moon and Mars. The Moon is treated as a true ellipsoid and is defined using a major axis and eccentricity. Mars is a sphere and defined by using the same values for the major axis and the minor axis. The ability to specify an ellipsoid using eccentricity or inverse flattening or minor
axis is very handy since the definitions of ellipsoids that are available to us will likely have one of these three parameters in addition to the major axis.

See any standard text on computational cartography for detailed discussions of eccentricity and inverse flattening. Inverse flattening is defined as \( \frac{\text{majorAxis}}{\text{major- minorAxis}} \). Eccentricity is defined as the square root of \( 1 - \left( \frac{\text{minorAxis}}{\text{majorAxis}} \right)^2 \).

**Tech Tip**

Manifold cannot use any customizations if the .xml files do not contain XML that is exactly correct. A useful test before launching Manifold is to open any newly created or modified .xml file in Internet Explorer. Internet Explorer will show a correct .xml file in a simple text format. If Internet Explorer cannot parse the .xml file, Manifold won't be able to either.
Custom Datums

Manifold uses datums in projection calculations. A datum is an ellipsoid that is combined with an offset of the ellipsoid relative to the Earth's center (defined as the center of the WGS84 datum). The definitions of datums available to Manifold are compiled into the product. User-supplied definitions may be loaded from .xml files found in the Config folder. If desired, users can add their own datums to incorporate other datums into Manifold.

Datums are defined by .xml files in the following pattern:

```xml
<xml>
  <datum>
    <name>My Datum</name>
    <ellipsoid>My Ellipsoid</ellipsoid>
    <centerX>0</centerX>
    <centerY>12</centerY>
    <centerZ>28</centerZ>
    <rotationX>0</rotationX>
    <rotationY>0</rotationY>
    <rotationZ>5</rotationZ>
    <scaleAdjustment>0</scaleAdjustment>
  </datum>
</xml>
```

Rules

- There can be any number of `<datum>` entries within a single XML file between the `<xml>` tag at the beginning of the file and the `</xml>` tag at the end of the file.
- The name string supplied in the `<name>` attribute is mandatory and must be unique. If the `<ellipsoid>` tag is used it must contain the name of an existing ellipsoid (user-defined ellipsoids are OK). The `<ellipsoid>` tag is not mandatory and can be replaced by an alternative specification of the ellipsoid using equivalent sets of tags, such as `<majorAxis>` and `<minorAxis>`, `<majorAxis>` and `<eccentricity>` or `<majorAxis>` and `<invFlattening>` tags.
- When using alternate specifications for ellipsoids, the `<majorAxis>` tag is mandatory and is the length of the major axis in meters. `<invFlattening>` is the value of the inverse flattening. The `<invFlattening>` attribute may be replaced with by the `<eccentricity>` attribute specifying the eccentricity of the ellipsoid, or by the `<minorAxis>` attribute giving the length of the minor axis in meters. A value for the minor axis that is greater than the major axis will be rejected.
- `<centerX>`, `<centerY>` and `<centerZ>` tags specify the offsets of the datum center along the X, Y and Z axis with respect to the center of WGS84, and are optional. The offset distances are in meters.
- `<rotationX>`, `<rotationY>` and `<rotationZ>` tags specify the rotation of the datum near the X, Y and Z axis with respect to WGS84, and are optional. The rotation angles are in whatever units are specified by the `unit` attribute. If no unit is specified, the rotation angles are in degrees.
- `<scaleAdjustment>` specifies the adjustment of the datum scale relative to WGS84, in units per million. That is, a scale adjustment of 1 means that the scale of the datum is 1.000001 that of WGS84.

To utilize newly created or modified datums place the new or modified .xml file containing the datums into the Config folder for Manifold (normally C:\Program Files\Manifold System Professional\Config) and restart Manifold.

When Manifold launches, the system will scan all .xml files in the Config folder. Any `<datum>` entries found in any of those .xml files will be loaded into the system as available datums.

Example

We've created a file in the Config folder called mydatums.xml that contains a new datum we would like to use with Manifold. The file contains:

```xml
<xml>
  <datum>
    <name>My Datum</name>
    <ellipsoid>My Ellipsoid</ellipsoid>
    <centerX>0</centerX>
    <centerY>12</centerY>
    <centerZ>28</centerZ>
    <rotationX>0</rotationX>
    <rotationY>0</rotationY>
    <rotationZ>5</rotationZ>
    <scaleAdjustment>0</scaleAdjustment>
  </datum>
</xml>
```
<name>My Datum</name>
<ellipsoid>Manifold 2001</ellipsoid>
<centerX>121</centerX>
<centerY>328</centerY>
<centerZ>15</centerZ>
</datum>
</xml>

When Manifold launches it will see the mydatums.xml file in the Config folder and will read it to see what it contains. It will find a definition for a datum called My Datum that uses an ellipsoid called Manifold 2001. If this ellipsoid is not part of the standard set of ellipsoids in Manifold, it must be defined elsewhere in an <ellipsoid> specification in one of our customizing .xml files.

Tech Tip

Manifold cannot use any customizations if the .xml files do not contain XML that is exactly correct. A useful test before launching Manifold is to open any newly created or modified .xml file in Internet Explorer. Internet Explorer will show a correct .xml file in a simple text format. If Internet Explorer cannot parse the .xml file, Manifold won't be able to either.

See the The Earth as an Ellipsoid for more information.
Custom Datum Grids for NTv2

Manifold allows definition of custom datum grids for the NTv2 transform. Datum grids are stored in GSB "grid shift" files and are described using XML files with the same name that contain one or more datum pairs to use with the grid.

The GSB files and XML files must be placed in the folder specified in the Tools - Options file location Datum Grids value. By default, this file location specifies a Grids folder within the main Manifold System installation folder.

XML File Format for Datum Transformation Pairs

A datum pair is defined using a <transform> tag. There can be more than one <transform> tag in an XML file for the GSB file.

The definition of a datum pair is done in the following pattern:

```xml
<xml>
  <transform>
    <source>Datum Name 2</source>
    <target>Datum Name 1</target>
  </transform>
</xml>
```

Both <source> and <target> tags specify the names of datums, and are mandatory.

The point of providing an XML file like the above is to tell Manifold the names of the datums that are to be converted with NTv2 using this grid shift file. Since NTv2 transformations are done only for a specific region, this assures that only those datums the names of which exactly match the datum names specified will be transformed using NTv2. Other datums will be transformed using the high accuracy, general purpose routines within Manifold.

Given a pair of source and target datums, Manifold will use the custom grid file to convert coordinates both from the source datum to the target datum and from the target datum to the source datum. Switching the order of the source and target datums will cause loss of precision.

Example

Suppose we want to use the NB7783V2.GSB grid shift file for converting from ATS77 to NAD83(CSRS) used in New Brunswick, Canada. We would provide an XML file named NB7783V2.xml that contained:

```xml
<xml>
  <transform>
    <source>ATS77</source>
    <target>NAD83(CSRS)</target>
  </transform>
</xml>
```

We would place both the NB7783V2.GSB file and the accompanying NB7783V2.xml file into a folder called Grids within the Manifold installation folder, or such other folder as we care to specify in the Tools - Options file location Datum Grids value.

When Manifold starts up, it will locate the .gsb file and accompanying .xml file and will load the ability to convert from ATS77 to NAD83(CSRS) using the grid file provided with NTv2.

Customization

Projections
Custom Coordinate System (Projection) Presets

Manifold includes a huge number of projections in the Projections pane. Each projection is really the definition of a coordinate system. Many coordinate systems are defined by standard formulas in which given parameters may be varied to create a specific coordinate system. Many projections such as various national grids are simply specific parameterized variants of a general projection that has been given a local name. A specific parameterized variant of a coordinate system in Manifold is called a preset.

Although fundamentally new types of coordinate systems cannot be added since these involve the creation of new program logic, users can add new variations of coordinate systems by providing named presets for customized versions of the standard projections within Manifold that do accept parameters.

The definitions of coordinate systems available to Manifold are loaded from .xml files found in the Config folder. If desired, users can add their own variations to incorporate “new projections” into Manifold. An example of a new projection preset is:

```
<xml>
  <preset>
    <name>My System</name>
    <category>National Grids*My Country</category>
    <system>Cassini</system>
    <centerLat>31.73</centerLat>
    <centerLon>35.21</centerLon>
    <falseEasting>170000</falseEasting>
    <falseNorthing>126800</falseNorthing>
  </preset>
</xml>
```

The <system> attribute specifies the base coordinate system that is being customized. Different coordinate systems allow different attributes. The above example shows attributes that can be used with the Cassini coordinate system.

**Rules**

- There can be any number of `<preset>` ... `</preset>` entries within a single XML file between the `<xml>` tag at the beginning of the file and the `</xml>` tag at the end of the file.
- The name string supplied in the `<name>` attribute is mandatory and must be unique.
- `<category>` is mandatory and represents the hierarchical path to the preset within the Projections dialog projections pane. Different levels of the hierarchical path are separated by an asterisk. For example, the preset above will appear within the National Grids folder in a My Country folder.
- `<system>` is mandatory and is the name of an existing Manifold coordinate system.
- Other attributes are parameters specific to the coordinate system, as listed below.

To utilize newly created or modified presets place the new or modified .xml file containing the presets into the Config folder for Manifold (normally C:\Program Files\Manifold System Professional\Config) and restart Manifold.

When Manifold launches, the system will scan all .xml files in the Config folder. Any `<preset>` ... `</preset>` entries found in any of those .xml files will be loaded into the system as available presets.

**Note:** in the tables listing tags below, such as those that may be used for parameters, it is understood that a `<tag>` is matched with a `</tag>`. Instead of writing `<tag>` ... `</tag>` in the tables to indicate a `<tag>` followed by some intermediate material and then closed with a `</tag>`, we simply write “<tag>”

Coordinate System Parameters Available in all Systems

All coordinate systems may include the following optional parameters. These may be used to specify an ellipsoid and other parameters within the coordinate system. See the Custom Ellipsoids and Custom Datums topics for information on ellipsoid and datum specification attributes.
Note: Although it is possible to define a coordinate system using `<majorAxis>`, `<eccentricity>`, `<centerX>`, `<centerY>` and `<centerZ>` tags, users are strongly advised to define a custom datum and then use the `<datum>` tag.

- `<majorAxis>`: Major axis of the ellipsoid.
- `<datum>`: Datum to be used for this coordinate system.
- `<eccentricity>`: Ellipsoid eccentricity.
- `<centerX>`: X offset to datum center in meters.
- `<centerY>`: Y offset to datum center in meters.
- `<centerZ>`: Z offset to datum center in meters.
- `<scaleX>`: X scale correction.
- `<scaleY>`: Y scale correction.
- `<falseEasting>`: False easting in meters or degrees.
- `<falseNorthing>`: False northing in meters or degrees.
- `<localOffsetX>`: X offset in meters or degrees.
- `<localOffsetY>`: Y offset in meters or degrees.
- `<localScaleX>`: X scale in meters or degrees.
- `<localScaleY>`: Y scale in meters or degrees.
- `<rotationX>`: Datum rotation about the X axis, in units specified by the `unit` attribute. By default, the rotation is in degrees.
- `<rotationY>`: Datum rotation about the Y axis, in units specified by the `unit` attribute. By default, the rotation is in degrees.
- `<rotationZ>`: Datum rotation about the Z axis, in units specified by the `unit` attribute. By default, the rotation is in degrees.

The above parameters will be applied in order they occur in the file except that the `<datum>` tag will always be applied before any other tags related to datum information.

Very Important: Note that the false Easting and Northing values are always given in meters or degrees, even in the case of those projections that traditionally use feet. When specifying projection presets one must always convert the desired false Easting and Northing values into meters for use in the XML specification. When the values are viewed in a Manifold coordinate system dialog they are converted to whatever units are active. So, what we see in an XML file is not the same to what we might see in a dialog.

Example

Some parts of South Carolina use a State Plane coordinate system that uses international feet as a measurement unit instead of survey feet. We could add this as a preset using the following XML:

```xml
<xml>
  <preset>
    <name>State Plane - South Carolina, NAD 83, Intl Feet</name>
    <category>Custom Presets</category>
    <system>Lambert Conformal Conic</system>
    <datum>North American 1983 (mean for CONUS)</datum>
    <unit>Foot</unit>
    <centerLat>31.833333333333333333</centerLat>
    <centerLon>-81.0</centerLon>
  </preset>
</xml>
```
Coordinate System Parameters

The following list of valid specifications for coordinate systems allowed in `<system>` attributes includes all parameters that may be specified for each. An attribute is a pair of tags with the value in between, as in `<centerLat>15</centerLat>`. Some coordinate systems, such as Latitude / Longitude have no optional parameters that are specific to that coordinate system. In addition to the parameters specified, all coordinate systems allow specification of common parameters.

Each coordinate system is listed by its `<system>` ... `<system>` name.

<firstLat> Latitude of the first reference location.
<firstLon> Longitude of the first reference location.
<secondLat> Latitude of the second reference location.
<secondLon> Longitude of the second reference location.
Oblique Mercator (B)

- `<centerLat>` Center latitude.
- `<centerLon>` Center longitude.
- `<centerLineAzimuth>` Azimuth of the center line.
- `<rectifiedGridAngle>` Rectified grid angle.

Oblique Mercator (B, centered)

- `<centerLat>` Center latitude.
- `<centerLon>` Center longitude.
- `<centerLineAzimuth>` Azimuth of the center line.
- `<rectifiedGridAngle>` Rectified grid angle.

Orthographic

- `<centerLat>` Center latitude.
- `<centerLon>` Center longitude.

Peirce

- `<centerLat>` Center latitude.
- `<centerLon>` Center longitude.

Polyconic

- `<centerLat>` Center latitude.
- `<centerLon>` Center longitude.

Robinson

- `<centerLon>` Center longitude.

Sinusoidal

- `<centerLon>` Center longitude.

Space Oblique Mercator

- `<ascendingNodeLon>` Longitude of the ascending node.
- `<completedOrbits>` Number of fully completed orbits.
- `<orbitInclinationAngle>` Orbit inclination angle.
- `<rotationToAscendingNode>` Earth rotation to the ascending node.
Customization

Space Oblique Mercator for Landsat

- `<orbitNumber>`: LANDSAT ID for the orbit.
- `<orbitPathNumber>`: LANDSAT ID for the orbit path.

Stereographic

- `<centerLat>`: Center latitude.
- `<centerLon>`: Center longitude.

Double Stereographic

- `<centerLat>`: Center latitude.
- `<centerLon>`: Center longitude.

Polar Stereographic

- `<centerLon>`: Center longitude.
- `<trueScaleLat>`: True scale latitude.

Tilted Perspective

- `<centerLat>`: Center latitude.
- `<centerLon>`: Center longitude.
- `<centerHeight>`: Center height in meters.
- `<tiltAngle>`: Tilt angle.
- `<tiltAzimuth>`: Tilt azimuth.

Transverse Mercator

- `<centerLat>`: Center latitude.
- `<centerLon>`: Center longitude.

Van der Grinten

- `<centerLon>`: Center longitude.

Van der Grinten IV

- `<centerLon>`: Center longitude.

Vertical Perspective
<centerLat> Center latitude.
<centerLon> Center longitude.
<centerHeight> Center height in meters.

Wagner IV
<centerLon> Center longitude.

Wagner VII
<centerLon> Center longitude.

Winkel Tripel
<stdLat> Standard latitude

**Tech Tip**

Manifold cannot use any customizations if the .xml files do not contain XML that is exactly correct. A useful test before launching Manifold is to open any newly created or modified .xml file in Internet Explorer. Internet Explorer will show a correct .xml file in a simple text format. If Internet Explorer cannot parse the .xml file, Manifold won't be able to either.

**Caution**

Defining custom presets for coordinate systems is an expert-level task that requires expertise in details of coordinate systems and projections. Correct choice of and use of parameters requires extensive knowledge of projections. Providing an incorrect specification or inappropriate parameters can provide erroneous system function. This capability is included within Manifold for the use of experts. It is not supported by any Manifold technical support product.

Custom Layout Templates

Manifold allows definition of custom layout templates. Layout templates are defined using XML files that contain one or more template definitions.

A layout template is defined using a <layout> tag. A layout template might also have an <elements> tag with one or more definitions for layout elements.

Layout templates are defined by .xml files in the following pattern:

```xml
<xml>
  <layout>
    <name>My Template</name>
    <pagesByX>1</pagesByX>
    <pagesByY>1</pagesByY>
    <elements>
      (layout elements go here)
    </elements>
  </layout>
</xml>
```

Rules

There can be any number of <layout>...</layout> entries within a single XML file between the <xml> tag at the beginning of the file and the </xml> tag at the end of the file. Within <layout> entries the following tags are used:

- <name> is mandatory and must be unique.
- <pagesByX> is optional and specifies the horizontal extent of the layout in pages. If the tag is omitted, applying the template preserves the horizontal extent of the target layout.
- <pagesByY> is optional and specifies the vertical extent of the layout in pages. If the tag is omitted, applying the template preserves the vertical extent of the target layout.
- <elements> is optional and contains zero or more definitions for the layout elements.

Layout Elements

Layout elements that may be defined inside the <elements> tag are:

- <body ref=... back=... background=... backgroundFore=... border=... borderDegMinSec=... borderEachPages=... borderFont=... borderFore=... borderMargin=... borderNoOverlaps=... borderRounding=... borderStep=... borderUnit=... columnHeaders=... controlPoints=... font=... fore=... graticule=... grid=... gridLines=... height=... legend=... northArrow=... pageFilters=... paging=... rotation=... scaleBar=... scope=... scopeDetail=... shadeAlternate=... visible=... width=... xmax=... xmin=... ymax=... ymin=... /> - The <body> tag defines a layout element for the parent component of the layout. If the layout does not have a parent component, the element defined by the <body> tag is ignored. The ref attribute of the <body> tag defines the reference name for the layout element and can be used to bind other layout elements to this element.
- <component ref=... back=... background=... backgroundFore=... border=... borderDegMinSec=... borderEachPages=... borderFont=... borderFore=... borderMargin=... borderNoOverlaps=... borderRounding=... borderStep=... borderUnit=... columnHeaders=... controlPoints=... font=... fore=... graticule=... grid=... gridLines=... height=... legend=... name=... northArrow=... pageFilters=... paging=... rotation=... scaleBar=... scope=... scopeDetail=... shadeAlternate=... visible=... width=... xmax=... xmin=... ymax=... ymin=... /> - The <component> tag defines a layout element for the component the name of which is given by the name attribute. If the project does not contain a component with such a name, or if the name refers to a component that can not participate in a layout, the element defined by the <component> tag is ignored. The ref attribute of the <component> tag defines the reference name for the layout element and can be used to bind other layout elements to this element.
- <legend refParent=... height=... rotation=... visible=... width=... xmax=... xmin=... ymax=... ymin=... /> - The <legend> tag defines a layout element for a legend. The legend is taken from the component used by the layout element with the value of the ref attribute equal to the value of the refParent attribute in the <legend> tag.
Attributes used within the layout elements listed above include the following attributes:

- `back=...` - Specifies the background color of a layout element. See the Custom Palettes and Themes topic for the format of a color value.
- `backgroundColor=...` - Controls the background of a layout element for a mappable component. Can be set to one of the following values: "auto" (turned on or off according to a component), "hide" (turned off) and "custom" (turned on, uses a custom color).
- `backgroundColorFore=...` - Specifies the custom background color of a layout element for a mappable component. If the value of the background attribute is not "custom", the value of the `backgroundColor` attribute is ignored.
- `border=...` - Specifies the border style of a layout element for a mappable component. Can be set to one of the following values: "none" (turned off), "coordinates" (turned on, uses custom coordinates), "coordinates (graticule)" (turned on, uses graticule coordinates), "coordinates (grid)" (turned on, uses grid coordinates), "thick" (turned on, thick) or "thin" (turned on).
- `borderDegMinSec=...` - Controls the format of lat/lon border coordinates of a layout element for a mappable component. Can be set to one of the following values: "true" (lat/lon coordinates use the degree-minute-second format) or "false" (lat/lon coordinates use the decimal degrees format).
- `borderEachPage=...` - Controls the appearance of the border of a layout element for a mappable component in a multipage layout. Can be set to one of the following values: "true" (the border is replicated on each page) or "false" (the border is shared between pages).
- `borderFont=...` - Specifies the font used to format the border coordinates of a layout element for a mappable component. See the notes at the end of this list for the format of the font value.
- `borderFore=...` - Specifies the color of the border of a layout element for a mappable component. See the Custom Palettes and Themes topic for the format of a color value.
- `borderMargin=...` - Specifies the width in printer's points of the border margin of a layout element for a mappable component.
- `borderNoOverlaps=...` - Turns clipping of overlapping labels in the border of a layout element for a mappable component on and off. Can be set to one of the following values: "true" (overlapping labels are clipped) or "false" (overlapping labels are displayed on top of each other).
- `borderRounding=...` - Specifies the number of digits to use when rounding the coordinate values in the border of a layout element for a mappable component. A value of 1 rounds to 1/10ths, a value of 0 rounds to whole numbers, a value of -1 rounds to tens and so on.
- `borderStep=...` - Specifies the interval between the coordinate values in the border of a layout element for a mappable component. The units of the interval are given by the value of the `borderUnit` tag. If the value of the border attribute is not "coordinates", the value of the `borderStep` attribute is ignored.
- `borderUnits=...` - Specifies the unit to use for the coordinate values in the border of a layout element for a mappable component. The number of units in the interval is given by the value of the `borderStep` tag. If the value of the border attribute is not "coordinates", the value of the `borderUnits` attribute is ignored.
- `columnHeaders=...` - Turns column headers in a layout element for a table component on and off. Can be set to one of the following values: "true" (turned on) or "false" (turned off).
• `controlPoints` - Specifies the output of the control points in a layout element for a mappable component. Can be set to one of the following values: "auto" (turned on or off according to a component), "hide" (turned off) and "show" (turned on).

• `font` - Specifies the font to use for a layout element for a comment, query, script or table component. See the notes at the end of this list for the format of the font value.

• `fore` - Specifies the foreground color of a layout element. See the Custom Palettes and Themes topic for the format of a color value.

• `graticule` - Controls the output of the graticule in a layout element for a mappable component. Can be set to one of the following values: "auto" (turned on or off according to a component), "hide" (turned off) and "show" (turned on).

• `grid` - Controls the output of the grid in a layout element for a mappable component. Can be set to one of the following values: "auto" (turned on or off according to a component), "hide" (turned off) and "show" (turned on).

• `gridLines` - Turns grid lines in a layout element for a table component on and off. Can be set to one of the following values: "true" (turned on) or "false" (turned off).

• `height` - Specifies the height of a layout element. See the notes at the end of this list for the format of the height value. If the layout element specifies both the `ymin` and `ymax` attributes, the value of the height attribute is ignored.

• `legend` - Controls the output of the legend in a layout element for a mappable component. Can be set to one of the following values: "auto" (turned on or off according to a component), "hide" (turned off) and "show" (turned on).

• `name` - Specifies the name of a component for a layout element defined by the `<component>` tag.

• `northArrow` - Controls the output of the north arrow in a layout element for a mappable component. Can be set to one of the following values: "auto" (turned on or off according to a component), "hide" (turned off) and "show" (turned on).

• `pageFilter` - Specifies the page filter for a layout element in a multipage layout.

• `paging` - Specifies the paging mode for a layout element in a multipage layout. Can be set to one of the following values: "continuous" (the component is stretched across all pages) or "individual" (the component is reproduced similarly on every page).

• `ref` - Specifies the reference name for a layout element defined by a `<body>` or `<component>` tag.

• `refParent` - Specifies the reference name of a parent layout element for a layout element defined by a `<legend>`, `<northArrow>`, `<scaleBar>` or `<text>` tag.

• `rotation` - Specifies the rotation angle of a layout element, in degrees.

• `scaleBar` - Controls the output of the scale bar in a layout element for a mappable component. Can be set to one of the following values: "auto" (turned on or off according to a component), "hide" (turned off) and "show" (turned on).

• `scope` - Specifies the scope of a layout element for a mappable component. Can be set to one of the following values: "entire component" (entire component), "locked rectangle" (a rectangle specified by the value of the `scopeDetails` attribute), "locked center / scale" (a view specified by the value of the `scopeDetails` attribute), "layer" (a layer specified by the value of the `scopeDetails` attribute), "selection" (the selection), "saved selection" (a saved selection specified by the value of the `scopeDetails` attribute), "view" (a view specified by the value of the `scopeDetails` attribute).

• `scopeDetail` - Specifies additional data for the scope of a layout element for a mappable component. If the value of the `scope` attribute is "locked rectangle", the value of the `scopeDetail` attribute is in the form "xmin,ymin,xmax,ymax", where `xmin`, `ymin`, `xmax` and `ymax` are the coordinates of a rectangle in the coordinate system of the component. If the value of the `scope` attribute is "locked center / scale", the value of the `scopeDetail` attribute is in the form "xcenter,ycenter, scale", where `xcenter` and `ycenter` are the center coordinates of a view in the coordinate system of the component and `scale` is the number of the coordinate units in the coordinate system of the component per pixel. If the value of the `scope` attribute is "layer", "saved selection" or "view", the value of the `scopeDetail` attribute is the name of the respective layer, saved selection or view.

• `shadeAlternate` - Turns shading of alternate rows in a layout element for a table component on and off. Can be set to one of the following values: "true" (turned on) or "false" (turned off).

• `size` - Specifies the width of the line for a layout element for a line or the width of the border line for a layout element for a rectangle. Can be an integer or one of the following values: "1/2", "1/3", "1/4", "1/5", "1/6", "1/8", "1/10", "1/12", "1/16", "1/20".

• `text` - Specifies the text of a text layout element. The text can include one or more escape sequences.

• `textAlignX` - Specifies the horizontal alignment of a layout element for text. Can be set to one of the following values: "center", "left", "right", "justify".

• `textAlignY` - Specifies the vertical alignment of a layout element for text. Can be set to one of the following values: "center", "top", "bottom".
• `textDecimals=...` - Specifies the number of decimal digits to use for escape sequences in a layout element for text.
• `visible=...` - Turns a layout element on and off. Can be set to one of the following values: “true” (visible) or “false” (hidden).
• `width=...` - Specifies the width of a layout element. See the notes at the end of this list for the format of the width value. If the layout element specifies both the `xmin` and `xmax` attributes, the value of the width attribute is ignored.
• `xmax=...` - Specifies the right bound of a layout element. See the notes at the end of this list for the format of the bound value.
• `xmin=...` - Specifies the left bound of a layout element. See the notes at the end of this list for the format of the bound value.
• `ymax=...` - Specifies the top bound of a layout element. See the notes at the end of this list for the format of the bound value.
• `ymin=...` - Specifies the bottom bound of a layout element. See the notes at the end of this list for the format of the bound value.

### Specifying Fonts, Bounds and Dimensions

Fonts are specified using the following format:

```plaintext
facename, size[, bold][, italic][, strikeout][, underline]
```

...for example,

```
Verdana, 8
Arial, 10, bold
Lucida Sans Unicode, 9, bold, italic
```

Bounds and dimensions of layout elements are specified as:

- A fraction of the page, for example, "0.5" for half of the page, "1.0" for the entire page.
- A percentage of the page, for example, "50%" for half of the page.
- A value in physical units, for example, "1in" or "1 in" or "1 inch" for 1 inch.

Command Filters

When configuring Manifold for use by naïve users an administrator may want to simplify the command interface presented by Manifold to eliminate commands that a naïve user should not be allowed to use. For example, we may want to eliminate commands such as the Edit - Projection command that can be used to change projections. This is easily accomplished using command filters.

A command filter is an XML file containing an arbitrary number of `<enable>` and `<disable>` entries. Each entry contains a regular expression pattern. Manifold uses these entries to enable or disable commands within the Manifold menu structure.

Launching Manifold with the `/cfilter:<path>` option starts Manifold using a command filter. For example, entering the following at the Windows command prompt (within the installation folder for Manifold) or within a batch file will launch Manifold using a command filter:

```bash
manifold.exe /cfilter:\myfiles\customizations\mymanifold.xml
```

The above will use the `mymanifold.xml` command filter file located in the `\myfiles\customizations\` folder.

To decide if a given command is enabled or disabled by the filter file, Manifold traverses all entries in the order they appear in the file, and matches the command name against the pattern in the entry. Case is significant in command names. If the command name matches the pattern, Manifold enables or disables the command as specified.

Example

The following command filter disables the Tools - Options command:

```xml
<xml>
  <disable>ToolsOptions</disable>
</xml>
```

Example

The following command filter disables all commands in the Tools menu, except the Tools - Options command:

```xml
<xml>
  <disable>Tools.*</disable>
  <enable>ToolsOptions</enable>
</xml>
```

Example

The following command filter disables all commands in the Tools and Drawings menus:

```xml
<xml>
  <disable>Tools.*</disable>
  <disable>Drawing.*</disable>
</xml>
```

Discovering Command Names

Launching Manifold with the `/clist:<path>` option creates a list of all available command names. For example, from the Windows command prompt (within the installation folder for Manifold) entering:

```bash
manifold.exe /clist:\commandlist.txt
```
…will create a `commandlist.txt` file in the root with a long list of command names, such as:

```plaintext
ChartData
ChartDataMoveDown
ChartDataMoveToBottom
ChartDataMoveToTop
ChartDataMoveUp
ChartDataSelectAll
ChartDataSelectInverse
ChartDataSelectNone
ChartDataShowTypes
ChartFormat
```

…and so on.

This provides a comprehensive list of names to use for command names when creating command filters. Keep in mind that some listed commands may not be available because of current activation status. For example, if Surface Tools have not been activated then any commands within Surface Tools cannot be enabled.

In addition, the list created by `clist` will include all internal commands known to Manifold, some of which are names that are reserved for future extensions.
Add-Ins

Add-Ins have two functions:

- Add-ins add new commands to the Custom toolbar or to the Tools - Add-Ins menu. Some of these commands may invoke custom panes.
- Add-ins control which Manifold toolbars are shown, hidden or disabled when the system starts up. Only one of the installed add-ins can control toolbars. To select which add-in controls toolbars, use the Add-In Manager dialog.

Add-ins are defined using .xml files that are placed within the Manifold System Config folder. To add new commands a text file containing a Manifold Script will also be required. Any Manifold script can be used, except those that include forms. Add-ins cannot execute scripts involving forms. When an Add-in executes, it always executes in non-debug mode even if the Debugger has been installed. To debug scripts, run them as ordinary scripts within the project using the debugger and then after they are debugged place them in a text file for use by the Add-in.

Add-ins may be written in any ActiveX scripting language or .NET language that is available on the machine.

Add-ins are defined by .xml files in the following pattern:

```xml
<xml>
  <addin>
    <name>My Add-in Name</name>
    <copyright>Copyright MyCompany Inc., 2001.</copyright>
    <description>Description goes here</description>
    <command>
      <icon>filename.png</icon>
      <name>Name to put in menu</name>
      <path>scriptfile.txt</path>
      <scriptEngine>VBScript</scriptEngine>
      <status>This text appears on the status bar</status>
      <tip>Tool tip text</tip>
    </command>
    <toolBar>
      <name>Toolbar Name</name>
      <display>hide</display>
    </toolBar>
  </addin>
</xml>
```

Rules

There can be any number of `<addin>` ... `<addin>` entries within a single XML file between the `<xml>` tag at the beginning of the file and the `</xml>` tag at the end of the file. Within `<addin>` entries the following attributes are used:

- `<name>` is mandatory and must be unique.
- `<command>` is optional. A `<command>` entry defines a command associated with the add-in.
- `<copyright>` is optional. It is a copyright string displayed within the Add-In Manager dialog.
- `<description>` is optional. It should be a short string that is displayed within the Add-In Manager dialog.
- `<reference>` is optional and contains a reference to an external module for .NET scripts. There can be more than one `<reference>` tag in the `<addin>` tag.
There can be any number of `<command>` ... </command> entries within an `<addin>` entry. Within `<command>` entries the following attributes are used:

- `<toolbar>` is optional. A `<toolbar>` entry controls the startup configuration of a Manifold System toolbar.

- `<icon>` contains a path to a graphics file containing the icon to be used for the toolbar button. The path can be either absolute or relative to the location of the Config folder. Graphics files can be in the same formats supported for icon point styles (BMP, GIF, JPG, PNG, TIF, etc) and will be autoscaled to 16 pixels wide and 15 pixels high in size. If the `<icon>` tag is present Manifold will create a new toolbar button on the Custom toolbar for this add-in. The `<icon>` tag may be omitted if the `<name>` tag is present. If there is no `<icon>` tag there will be no button created on the Custom toolbar for this add-in.

- `<form>` contains the programmatic name of the form to use for the command in a menu. If the form is an ActiveX control, the `<form>` tag should contain the programmatic ID of the control object. If the form is a .NET control, the `<form>` tag should contain either a name or a path to the assembly containing the control class and the name of the class, separated by a semicolon. The path to the assembly can be either absolute or relative to the location of the Config folder. If the `<form>` tag is present, the `<path>` tag can be omitted. If both the `<form>` and the `<path>` tags are present, the `<form>` tag is ignored.

- `<name>` contains the name string to use for the command in a menu. If the `<name>` tag is present, Manifold will create a new entry with that name for this add-in in the Tools - Add-Ins menu. If present, the `<name>` text must be unique. The `<name>` tag may be omitted if the `<icon>` tag is present. If there is no `<name>` tag within a `<command>` there will be no menu entry created.

- `<path>` contains the path to a text file containing the script text for the command. The path can be either absolute or relative to the location of the Config folder. If the `<form>` tag is present, the `<path>` tag can be omitted, otherwise the `<path>` tag is mandatory. If both the `<form>` and the `<path>` tags are present, the `<form>` tag is ignored.

- `<scriptEngine>` is optional and contains the programmatic ID of the ActiveX script engine or a string literal identifying the .NET script engine (".NET", "JScript.NET", "IronPython.NET", or "VB.NET"). If omitted, the system assumes the add-in is written in VBScript.

- `<nameStrict>` is optional and controls name recognition. Add-in commands can use the `<nameStrict>` tag to specify strict command names for filtering purposes. The system makes sure all add-in commands start with "Addin", so a command named "AddinCommand" is registered as "AddinCommand", but a command named "Tool" is registered as "AddinTool".

- `<status>` is optional and provides text to place on the main Manifold status bar when the mouse hovers over the toolbar button associated with the add-in command.

- `<tip>` is optional and provides tool tip text that appears when the mouse hovers over the toolbar button associated with the add-in command.

There can be any number of `<toolbar>` ... </toolbar> entries within an `<addin>` entry. Within `<toolbar>` entries the following attributes are used:

- `<name>` is mandatory and contains the toolbar name as it is shown in Manifold.

- `<display>` is mandatory and specifies the toolbar display state as show, hide or disable.

In the `<display>` attribute, show means to show the toolbar by default for those components that normally use that toolbar. hide means to not display the toolbar by default but to allow it to be chosen for display through the Tools - Customize dialog. disable does not show the toolbar and also prevents it from being listed in the Tools - Customize dialog. Use disable to prevent a toolbar from ever being used.

Adding Commands

Adding a command requires writing a script that implements the command and then arranging an Add-in that adds the command to the system when Manifold is launched. Write the script text into a .txt file, create a graphics file for the toolbar button icon and create an .xml file. Place the files within the Config folder hierarchy for Manifold (normally C:\Program Files\Manifold System\Config) and restart Manifold.

When Manifold launches, the system will scan all .xml files in the Config folder and all sub-folders within the Config folder. Any `<addin>` ... </addin> entries found in any of those .xml files will be loaded into the system as available add-ins.

Example
We will add a toolbar button that when pressed pops open a message box to say "Hello, world!" To do so, we create a subfolder in the Config folder called hello. Within hello we’ve created three files: hello.xml, hi.png and hello.txt.

The hi.png file contains an image that is 16 pixels wide and 15 pixels high.

![Hi.png](attachment:Hi.png)

Seen in Manifold with the border turned on, the hi.png file contains pixels spelling out the word "Hi" in red color. Other pixels are transparent color. In menus, Manifold will replace transparent color with light gray color (192, 192, 192) to match default Windows desktop settings.

The hello.txt file contains the scripting text to use:

```vbs
Sub Main
    Application.MessageBox "Hello, world!", "Traditional Greeting"
End Sub
```

The "Traditional Greeting " text specifies the text to put into the title bar of the message box.

The hello.xml file contains the XML configuration information to add the add-in into Manifold:

```xml
<xml>
    <addin>
        <name>Hello World Add-In</name>
        <copyright>Copyright MyCompany Inc, 2001.</copyright>
        <description>Simple add-in with single command.</description>
        <command>
            <icon>hello\Hi.png</icon>
            <name>Say Hello</name>
            <path>hello\hello.txt</path>
            <scriptEngine>VBScript</scriptEngine>
            <status>Displays traditional first program text.</status>
            <tip>Say Hello</tip>
        </command>
    </addin>
</xml>
```

Note that the paths to the filenames in the `<icon>` and `<path>` attributes are given relative to the Config folder.

When Manifold launches it will see the hello.xml file within the hello folder in the Config folder and will read it to see what it contains. It will find an add-in and will place the icon on the Custom toolbar as well as placing a Say Hello entry within the Tools - Add-Ins menu. When that toolbar button is pressed or the menu command is invoked the script in hello.txt will be executed and a message box will pop open.

This example is a very simple one. Since any Manifold script (except those using a form) can be executed, very complex add-ins can be created. In fact, one could install one or more COM objects and then call those objects from within an add-in.

**Advanced Example: Toolbar Configuration**
Add-ins can control the default configuration of toolbars by including `<toolbar>` entries. In fact, an add-in might not have any `<command>` entries but only have `<toolbar>` entries to control default toolbar configuration without adding any commands.

This example includes both a command as well as toolbar configuration entries. It uses the same `hi.png` graphics file as well as a `hi.txt` script file and a `hi.xml` XML file. All three are placed within a folder called `hi` within the `Config` folder.

The `hi.txt` file contains:

```vbscript
Sub Main
    Application.MessageBox "Hello from advanced add-in!", "Advanced Add-In"
End Sub
```

The `hi.xml` file contains:

```xml
<xml>
<addin>
    <name>Hi Advanced</name>
    <copyright>Copyright MyCompany Inc, 2001.</copyright>
    <description>Advanced add-in with single command.</description>

    <command>
        <icon>Hi\Hi.png</icon>
        <name>Say Hi (Advanced)</name>
        <path>Hi\Hi.txt</path>
        <scriptEngine>VBScript</scriptEngine>
        <status>Displays advanced welcome message.</status>
        <tip>Say Hi (Advanced)</tip>
    </command>

    <toolBar>
        <name>Alignment</name>
        <display>hide</display>
    </toolBar>
    <toolBar>
        <name>Query</name>
        <display>hide</display>
    </toolBar>
    <toolBar>
        <name>Tools</name>
        <display>disable</display>
    </toolBar>
    <toolBar>
        <name>Tools (Advanced)</name>
        <display>disable</display>
    </toolBar>
    <toolBar>
        <name>Tracing</name>
        <display>hide</display>
    </toolBar>
    <toolBar>
        <name>Transform</name>
        <display>hide</display>
</addin>
</xml>
```
The most important thing about the above XML is that it completely disables the **Tools** and **Tools (Advanced)** toolbars that would normally be used to create forms.

**Advanced Example: Creating a Custom Pane**

Add-ins can be used to create custom panes. This example demonstrates how to create a custom pane using Visual Basic 2005 Express.

1. Launch Visual Basic 2005 Express. Create a new Class Library project (File - New Project, Class Library) named **MyPane**.

2. In the Solution Explorer window, right click **Class1.vb** and select **Delete**.

3. In the Solution Explorer window, right click **MyPane** and select **Add - User Control**. Set the control name to **MyPaneControl** and click **Add**.

4. In the **MyPaneControl.vb** design window, add a button (Toolbox, Common Controls, Button) and a label (Toolbox, Common Controls, Label). Double click the button to add a handler for the button's Click event.

5. In the Solution Explorer window, right click **MyPane** and select **Add Reference**. In the **Add Reference** dialog, switch to the **Browse** tab, locate the Manifold installation folder, select **Manifold.Interop.dll** and **Manifold.Interop.Scripts.dll** and click **OK**.

6. In the **MyPaneControl.vb** code window, select all text and replace it with:

```vbnet
Public Class MyPaneControl
    Implements Manifold.Interop.Scripts.IEventsConnection

    Dim app As Manifold.Interop.Application

    Private Sub Button1_Click( _
        ByVal sender As System.Object, _
        ByVal e As System.EventArgs) Handles Button1.Click
        If Not (app Is Nothing) Then
            app.MessageBox("The document contains " + _
                ", component(s).")
        End If
    End Sub

    Public Sub ConnectEvents( _
        ByVal ev As Manifold.Interop.Scripts.Events) _
        Implements Manifold.Interop.Scripts.IEventsConnection.ConnectEvents
        AddHandler ev.DocumentClosed, AddressOf Document_Changed
        AddHandler ev.DocumentCreated, AddressOf Document_Changed
        AddHandler ev.DocumentOpened, AddressOf Document_Changed
        AddHandler ev.DocumentSaved, AddressOf Document_Changed
    End Sub

    Private Sub Document_Changed( _
        ByVal sender As System.Object, _
        app = args.Document.Application
        Label1.Text = args.Document.Path
    End Sub
End Class
```
7. Invoke Project - Show All Files. In the Solution Explorer window, expand MyPane then MyProject and finally double click AssemblyInfo.vb. Locate the line which sets the value of the ComVisible attribute to False, and change it to set the value of the attribute to True:

```
<Assembly: ComVisible(True)>
```

8. Build the class library by using Build - Build MyPane. Make sure there are no build errors.

9. Save the code and the compiled binary by using File - Save All.

10. Launch Windows Explorer and locate the folder you saved the project to. Descend into bin\release, copy MyPane.dll and paste it into the Manifold configuration folder (usually, C:\Program Files\Manifold System\Config). If you do not have write permissions in the configuration folder, launch Manifold and change the file location for that folder to point to where you have write permissions.

11. In Windows Explorer, create a new XML file in the configuration folder and name it MyPane.xml for convenience (this file is different from MyPane.xml generated by Visual Basic). Drag and drop the created MyPane.xml into the opened instance of Visual Basic, set its text to:

```
<?xml version="1.0"?>
<xml>
  <addin>
    <name>My Pane</name>
    <command>
      <name>My Pane</name>
      <form>MyPane.dll;MyPane.MyPaneControl</form>
    </command>
  </addin>
</xml>
```

Save the MyPane.xml file. That's all!

To test the pane, launch a new instance of Manifold. Note that the Tools - Add-Ins menu contains a new command named My Pane. Invoke that command to show the pane. Create a new project. The pane label should become blank. Create a new drawing, then press the pane button. The pane should report that the project .map file contains two components (a drawing and a table). Save the project. The pane label should update its text with the path to the .map file.

**Add-ins and Forms**

Add-ins can include forms, used as modeless panes. Forms can be either ActiveX controls or .NET controls.

To include a form into an add-in, create a command item using the `command` tag, supply the name of the form using the `name` tag and supply either the ProgID of the ActiveX control or the name of the .NET control using the `form` tag. The name of the .NET control should include the name of the assembly or path to the assembly module (either absolute or relative from the Config folder) and the name of the .NET class separated by a semicolon.

**Tech Tips**

Manifold cannot use any customizations if the .xml files do not contain XML that is exactly correct. A useful test before launching Manifold is to open any newly created or modified .xml file in Internet Explorer. Internet Explorer will show a correct .xml file in a simple text format. If Internet Explorer cannot parse the .xml file, Manifold won't be able to either.

Add-in forms implemented as .NET controls can subscribe to events fired by the Manifold core at runtime. To do this, include a reference to Manifold.Interop.dll and Manifold.Interop.Scripts.dll, implement the
The `IEventsConnection` interface from the latter dll and add handlers to the desired events in the `ConnectEvents` method of the interface.

Enterprise Edition

Enterprise Edition

Manifold System **Enterprise Edition** is a version of Manifold System that includes additional capabilities not found in the Professional Edition or Personal Edition versions. If you have purchased and installed Enterprise Edition the features described in this and other Enterprise topics will be available to you. If you have installed the standard Professional Edition or Personal Edition of Manifold System you will not be able to use these features.

Enterprise Edition features are also found in Enterprise superset editions of Manifold System, such as Database Administrator Edition or Universal Edition.

In addition to support for classic desktop and server storage models, Manifold's Enterprise Edition also provides a new storage model, a shared Enterprise server model, which combines the advantages of both desktop and server storage. Users new to Manifold sometimes think that using Enterprise Edition requires use exclusively of Enterprise servers. That's not the case: Enterprise Edition supports all three storage models. In fact, all three storage models can be used at the same time within the same project and often are.

Please read the Data Storage Strategies topic to understand how Enterprise servers fit into classic ideas about GIS data storage.

**Enterprise Edition Features**

**Export to .e00 Format** - Enterprise Edition allows export to ESRI .e00 format as well as to the export formats for drawings supported by Professional Edition (ESRI .shp, MapInfo .mid/.mif, Manifold 4.50, AutoCAD .dxf and US Federal SDTS format).

**Shared Storage in Centralized DBMS** - Enterprise Edition can store any Manifold component within a database using a specialized storage model unique to Manifold System called an **Enterprise server**. A Manifold Enterprise server can be hosted on almost any enterprise-class database management system such as IBM DB2, Microsoft SQL Server, and Oracle. DB2, SQL Server and Oracle are officially supported while many other DBMS systems, such as MySQL have been tested and are known to work but are not officially supported.

**Use One Component in Many Projects** - A single copy of a component like a drawing or image can be used in hundreds of projects, but only a single copy need be kept within the Enterprise server. This saves disk space when the same component is used in many different projects.

**Project Coordination via Enterprise Servers** - Enterprise Edition enforces access control and controlled editing of shared components so that many users at once can use the same components. Edits can be made using an easily understood "check out" procedure so that simultaneous, incompatible edits cannot be made. Users can continue using shared components even when someone else has checked them out for editing.

**Concurrent Multi-User Editing** - In addition to the simplified, documented oriented storage model offered by Enterprise Edition using Manifold Enterprise servers, Enterprise Edition also supports truly concurrent, fully multi-user, fully-scalable editing of linked drawings at the object level using drawings linked in a classic server storage model. This allows multi-user editing of drawings of virtually limitless size by a virtually unlimited number of users with storage using standard DBMS geometry types or Oracle Spatial SDO_GEOMETRY that is accepted industry-wide.

**Native Spatial DBMS Support** - Enterprise Edition can store and retrieve vector geometry (drawing objects) and images within native spatial DBMS products such as Oracle Spatial, IBM DB2 with Spatial Extender, SQL Server 2008 spatial (Katmai) and PostgreSQL. Drawings may be exported into spatial DBMS storage with automatic use of the spatial DBMS package's native geometry types, spatial indices and supporting facilities. In addition, Enterprise Edition can store images and surfaces within Oracle databases that include Oracle's GeoRaster technology.

**Generic Spatial Indices** - Enterprise Edition can store drawings, images and surfaces within almost any ordinary DBMS in a way that provides true spatial DBMS capability even if the DBMS does not have its own geometry types and associated spatial facilities such as spatial indices. Once Enterprise Edition has been used to store components in this way then any Manifold license can utilize those components.

**Manifold Spatial Extender for SQL Server** - Enterprise Edition is required to create spatial indices using the Manifold Spatial Extender for SQL Server. Once drawings have been uploaded into SQL Server that is equipped with the Manifold spatial extender, any Manifold edition may be used to import or link those drawings.
Area of Interest Windowing - A key part of unlimited, Enterprise class deployment of GIS applications is the ability to constrain display and editing to a specific, desired region, the Area of Interest (AOI), that is part of what is usually an immensely larger drawing. Manifold Enterprise Edition can work with spatial databases to allow fast and easy specification of an area of interest within a larger drawing: only that part of the drawing will be extracted for use with Manifold, and the part extracted will be fully dynamic and interactive with all viewing, editing and analytic capabilities available to any linked drawings. This Enterprise Edition feature makes it practical for potentially thousands of users to each work with their own areas of interest within drawings that could be terabytes in size. Enterprise Edition is required to use AOI windowing with native spatial DBMS and is required to set up the spatial indices that provide AOI windowing in non-native spatial DBMS.

Manifold Enterprise Server Shared Storage Model

The Enterprise server storage model is an innovation by Manifold that is unique to Manifold System. As discussed in the Data Storage Strategies topic, it provides a storage model that combines the simplicity and convenience of the desktop, document-oriented storage model with many of the organizational benefits of the more complex server, object-oriented storage model while in general avoiding the need for managers to become expert DBMS administrators. It is a tremendous convenience for organizations or individual users who have large or complex data holdings.

Centralized storage via Enterprise servers allows multi-user sharing of common components so different users can simultaneously use the same component within their projects. For example, many users in a town's GIS department can use the same base map drawing of a town within their projects. That means any changes to that base map drawing need be made only in one place. Another benefit to storage of components within an Enterprise server, in addition to the shared access thus provided, is the ability to share a single copy of a component within many different projects so that room for only one copy of the component need be consumed on disk.

For example, if the same drawing of Europe or the US is frequently re-used as a background layer in a map we can share that drawing into an Enterprise server and then share it into a project whenever needed. Only one copy of the drawing will be maintained, the copy within the Enterprise server. If a drawing or other component (such as an image) is used in hundreds of different projects we will see considerable savings in disk space.

A tremendous advantage of Enterprise server storage for both organizations and individuals comes when we need to update some component that is used in many projects. Let's consider an example:

Suppose we have a drawing, such as a boundary lines layer, that is often used as a background layer in maps we create. Over time such a drawing might be used in hundreds of projects that are mixed in among thousands of projects a particular consultant or organization might create. Suppose one day that drawing has to be updated with some changes to the boundaries. That can be a really difficult job if ordinary, desktop computing document storage is used to save everything in a project file.

This is a nightmarish situation many GIS professionals have encountered, when they discover that they have to figure out which of many thousands of project files that might be scattered across disk drives on many machines use that particular drawing. Worse yet, to update all of those projects we would have to open each individual project file and then copy the updated layer from a new project and paste it into that project to update it. What a hassle!

In contrast, if we used Enterprise Edition we could have kept the boundaries layer on an Enterprise server and then linked it into every project that used it as a shared component. In that case, when it came time to update the boundaries layer all we would need to do is simply check it out from the Enterprise server, edit it and then check it back in. When we check it back in, every project that uses that drawing no matter where it is located will be automatically updated. In this case, using Enterprise Edition changes a nightmarish project that we never could be certain would be accomplished even though weeks of effort might go by into a very simple project that could be finished in a few minutes with total certainty that it had been done right.

Obviously, the sooner we start using Enterprise servers to store our data the sooner we can benefit from centralization of our data holdings. Many experienced individuals will begin storing their data in Enterprise servers even when the number of drawings they use and the projects they create are relatively few. They know that in the blink of an eye what starts out as small holdings will grow into many gigabytes of components and projects.

Database Servers
Database vendor websites provide free downloads of complete installation packages for the Express editions of all three of the "Big 3" enterprise-class database management systems supported by Manifold Technical Support for use with Enterprise Edition. Installing any of these three database packages gives Manifold users the ability to achieve high performance, centralized DBMS storage within Manifold Enterprise servers using world-class DBMS products without any additional purchase required.

In alphabetical order, DBMS packages supported by Manifold include:

- **IBM DB2 Express-C** - Based on the IBM DB2 engine. DB2 Express-C is limited to 4 GB of RAM and two processors, but has no limits on database size or the number of users. DB2 provides the largest capacity of any of the Express editions. See the IBM DB2 Express-C Edition topic for more. Native spatial DBMS capability is available for DB2 via the IBM Spatial Extender for DB2, which is a free download for DB2 Express-C users.

- **Oracle 10g Express Edition** - Based on the Oracle 10g Enterprise engine. Oracle 10g Express is limited to 4GB maximum database size, up to 1 GB of RAM and one processor core. Oracle Express includes Oracle's famous spatial technology for high performance storage of drawing geometry, enabling Manifold area of interest windowing. See the Oracle Express Edition topic for more.

- **SQL Server 2005 and 2008 Express** - Based on the SQL Server engine. SQL Server 2005 Express and 2008 Express are limited to 4GB maximum database size, up to 1 GB of RAM and one processor core. SQL Server includes exquisite integration with Microsoft development environments. See the SQL Server Express Edition topic for more. SQL Server 2005 Express (SP2 and greater) may be used as a spatial DBMS when the Manifold Spatial Extender for SQL Server has been installed on the SQL Server machine.

**Shared Storage on Enterprise Servers**

In addition to support for standard desktop storage models and standard server storage models, Manifold's Enterprise Edition uses a new approach to centralized storage of data within DBMS providers.

The standard server storage model as used by classic spatial DBMS is to store objects within a DBMS at the "atomic" object level. Although there are many merits to this approach and it is fully supported by the extensive spatial DBMS capabilities of Manifold, it can be overkill for many users. It can place a greater load on the DBMS administrator, requiring a higher level of technical expertise to keep things running smoothly.

Enterprise Edition provides an alternative, which combines the conveniences of desktop storage with the organizational strengths of server storage. Shared storage using Manifold Enterprise servers stores the entire component within the DBMS, basically using the DBMS as a centralized file cabinet with supervisory capabilities.

In the Manifold shared Enterprise server model, when a drawing, image, surface or other component is shared on a database the master copy of the data is kept within the DBMS, called an Enterprise server. Whenever a user wants to work with a component saved in the Enterprise server, he or she can link the component into the project at hand. Behind the scenes, Manifold fetches a temporary working copy of the entire component into local memory.
The Manifold model has many benefits, including excellent speed once remote components are linked into the local project as compared to high-granularity older architectures. All operations happen within local memory so operations using shared components are just as fast as those using local ones. If a user wishes to edit a shared component, he or she can check it out for local editing, and then check it back into the Enterprise server when done editing.

This check out / check in model of usage is inspired by the highly successful source code control model used within many development environments for collaborative program development by large teams. It is well understood in the software industry and has proven very efficient as a means of managing multiple edit operations by many users.

**Note:** In all fairness, there are faster ways of running classic server storage models than are used by some legacy systems. For example, Manifold Enterprise Edition can connect to Oracle Spatial or other data stores using classic server model linked drawing storage. However, Manifold knows to use intelligent caching whenever possible so that more efficient DBMS accesses can be commanded for much faster performance than possible with some old fashioned systems.

When Manifold Enterprise Edition is used with linked drawings from a fast DBMS data source such as DB2, Oracle, or SQL Server the performance can approach or exceed that of local storage. In some cases, such as area of interest windowing into very large data sets stored on Oracle spatial servers, the performance will significantly exceed that of either local storage or shared Enterprise server storage.

**Advantages of Shared Enterprise Server Storage**

Enterprise Edition storage within Enterprise server geospatial databases has many benefits compared to either desktop models or classic server storage models. The shared Enterprise server installation provides the following benefits:

- Faster performance, at times by a factor of 100 or more in interactive GIS operations as compared to older architectures that have high granularity.
- Reliable, conflict-free editing of complex data in an environment where many users share the same data. Surprisingly, even some very expensive older systems cannot guarantee conflict-free editing as does Manifold.
- Freedom to choose almost any DBMS vendor. Enterprise Edition works with dozens of different database management systems without any need for special DBMS versions, special modules or costly middleware. The Manifold model by default allows use of almost any DBMS that allows transactions and that has an ODBC or OLE DB driver.
- Heterogeneous, free form utilization of Enterprise servers. Within the same project Manifold can transparently include multiple components from different Enterprise servers hosted by different DBMS vendors.
- DBMS safety. If the DBMS crashes while working on an Enterprise project the project is still safe and can be saved with no loss of data.
Network fault tolerance. If the network crashes while working on an Enterprise project the project is still safe. Transient disconnects won’t even be noticed, and lengthy disconnects still allow a local save of the project. Work can continue even without the network. When the network comes back up the project can be opened and automatic synchronization will occur.

Ability to use Internet. The high bandwidth requirements of older architectures mean that connecting over Internet to a remote DBMS is not usually realistic. With Manifold, the more efficient Enterprise architecture means that it is realistic in many cases to connect to an Enterprise server via corporate Internet links.

Off-line working capability. Older systems cannot work without a constant, "live" connection to the DBMS. Manifold allows transparent off-line work, such as with laptops when travelling away from a direct connection to an Enterprise server. Users can continue working while away from their corporate network.

Disadvantages of Shared Enterprise Server Storage

Although shared storage on Manifold Enterprise servers has many benefits, it does have some disadvantages as compared to either desktop models or classic server storage models:

- Exclusively Manifold usage. Enterprise servers cannot realistically be used by other GIS software. In exchange for the convenience of an easy to use environment the organization must use Manifold Enterprise Edition licenses on all clients. However, because Manifold Enterprise Edition also supports storage in "open" server storage models, users who desire interoperability with other GIS packages can also use linked drawings within classic server storage, such as within Oracle Spatial.
- No concurrent multi-user editing. Enterprise servers reduce the complexity of administration and reduce user skill set required by simplifying the shared usage of components. Many users can include shared components in their projects on a read-only basis, but only one user at a time can check out that shared component for editing. While checked out, that component may be edited only by that user. Once the component is checked back into the server, any changes made will propagate to all projects that use that component and a different user can then check out the component if desired.
- No support for area of interest windowing. When drawings are stored in Oracle databases Manifold can link only a portion of a drawing, the area of interest, into a project. It is usually the case when very large drawings are edited that each user is editing only a very small portion of the drawing. By linking in only that portion of interest, which is usually a few tens of megabytes of data, users can effectively work with drawings that are so large, potentially terabytes in size, that they could never be edited on a desktop machine. Because Enterprise Edition pulls the entire drawing from an Enterprise server it cannot be used to work with drawings that are larger than can fit within the performance characteristics of the desktop machine being used as a client.
- Greater complexity for programmatic access to objects. The Manifold API allows users to reach into Enterprise servers to obtain individual objects (that is, individual points, lines and areas) from within a drawing shared on the server, but doing so usually requires more skill than access to individual objects via storage methodologies that are more object oriented.
- Requirement for a database installation. This is really a disadvantage only as compared to the desktop storage model as the classic server storage model also requires a database. In earlier times the cost of a suitable enterprise-class DBMS might have been an obstacle, but given that DBMS vendors now provide free installations of the Express editions of the "Big 3" DBMS products, cost of a database installation is no longer a disadvantage. There is still the slight additional managerial overhead of installing a DBMS server on a machine.

Note that the above disadvantages can be avoided, if required, by using Manifold to store data in a server storage model using linked drawings. Manifold is perfectly happy supporting our work with whatever storage model we choose, be it local desktop storage, shared Manifold Enterprise server storage or linked server storage in the classic way. The advantages and disadvantages enumerated above apply to the shared Manifold Enterprise server model and are set forth so we can decide when we want to use that model.

In particular, none of the disadvantages apply when we use Manifold for server storage in the classic way, saving drawings and possibly images and surfaces within an enterprise-class DBMS like DB2, Oracle or SQL Server. We can even freely combine storage models within the same project to mix and match advantages and disadvantages as we see fit to optimize our storage strategy for a particular project or IMS application.

Enterprise Servers

Once a database has been created to which a Manifold component has been shared it is said to be an Enterprise server. Components stored within an Enterprise server are said to be shared components. Users accessing an Enterprise server using Enterprise Edition are said to be Enterprise users.
To create an Enterprise server we initialize the database and share at least component to it. Thereafter, any Enterprise user can fetch and use components from the Enterprise server. There are two ways for user to work with components saved within the Enterprise server:

- **Import** components from the Enterprise server. When importing components from the server a local copy of the component is made and work proceeds on that local copy without further connection to the server. Enterprise servers used in this way function simply as a centralized repository from which users may fetch components as desired for their local purposes.

- **Link** components from the Enterprise server. When a component is linked from the server the component continues to reside within the Enterprise server with controls on how that component can be used by different users at the same time. It is said to be a *shared* component. Enterprise Edition provides several ways of working with shared components that allow coordination between multiple simultaneous users.

Enterprise users can share components using the following commands, which appear in the context menu when right-clicking onto a component in the project pane:

- **Share** - Save a component into the Enterprise server. Use this command to load the Enterprise server with shared components.

- **Unshare** - Convert a shared component into a local component. The data from the Enterprise server will be downloaded to the local project and all connection to the Enterprise server for this component will be ended.

- **Check Out** - Gets the latest version of a shared component and makes it editable exclusively by user. Only one user at a time can check out a component. Other users can still link the component, but they will not see any changes we make until we check in that component.

- **Check In** - Saves the edited version of a component back to the Enterprise server and makes the component read-only in our project. When we are done editing a shared component we can **Check In** to save the changed version of the component to the Enterprise server. After we check in, any user getting that component will get the newly edited version.

- **Get Latest Version** - Fetches the latest version of a shared component. If we are working with a shared component and suspect that someone might have checked out the component we are using and altered it, we can use **Get Latest Version** to fetch the latest version.

- **Undo Check Out** - Enabled if we have used **Check Out** to get a component for editing. Abandons any changes we have made to a shared component on our local system, gets the latest version from the server and makes it read-only.

- **Link** - Appears in the File menu and in the Tools - Server Console dialog. Fetches the latest version of a shared component for use in our project. This opens a shared component in a read-only mode. We can view the component and allow it to participate in maps we create, but we cannot edit it.

- **Cached** - Shared components are cached by default. We can designate a component to be uncached by right clicking on a shared component in the project pane and choosing **Cached** from the pop-up context menu to toggle the check mark next to the **Cached** entry. Tool tips and the project pane status bar will show the cached/uncached status of each shared component. See the Cached and Uncached Components topic.

The above commands will be familiar to users of Microsoft Visual SourceSafe source code control system, if one understands **Link** to mean SourceSafe’s **Get**. The Manifold commands have, in fact, been deliberately designed to retain conceptual compatibility with similar commands used within source code control systems to resolve multi-user access and conflicts issues in complex development projects.

### Remote, Shared and Local Components

Components that are stored in an Enterprise server or which are linked in from other data sources are called **remote** components. Components in an Enterprise server that are linked into the current project are called **shared** components. Components that are stored within the project are called **local** components. A project can contain any combination of local or shared components. Shared components from many different Enterprise servers may be included within the same project.

The project pane shows shared components with a small **gray lock** icon next to the component icon to show they are read only. A component that is checked out by us will have a small **red check mark** icon. A component that is checked out by someone else will have a small **dark blue lock** icon. If someone else has checked out a component and edited it, the icon for that component will appear as a **dark red lock** icon. This indicates that if we want to work with the latest version of that component we should do a **Get Latest Version**.
Tool tips show the status of a shared component when the mouse hovers over it in the project pane. If a component is not checked out it will be reported as a shared component using the name of the Enterprise server data source. In the above example, the Roads Drawing component is shared on an Enterprise server data source called Enterprise example.

If we check out the component the icon turns to a red check mark and the tool tip reports it as being checked out.

If someone else checks out the component the icon turns to a black lock and the tool tip reports which user checked it out. In the above example, a user called Administrator on a machine called PROJECT has checked out the component. Tool tips report which user has checked a component so we can get in contact with them should we want them to check the component in so that we can check it out for editing.

If someone else checks out the component, changes it and then checks in the component, the icon turns to a dark red lock in our project. This lets us know it is time to get the latest version. The tool tip reports that the component is that it is outdated.

**Forms Cannot be Shared**

Forms components cannot be shared to an Enterprise server. The reason why not is that forms can contain programming controls which cannot be guaranteed to be available on the client computer. In some cases, users may employ licensed controls within their forms that are not redistributable to other computers without a license grant by the originating vendor.

**Nomenclature**

Although Enterprise components are brought in from the Enterprise server using a "link" command once they are in the project they are called "shared" components. Within Manifold, the term "linked" component is used to refer to tables that are linked into the project from an external data source other than an Enterprise server.

The main operational distinction between a linked table and a shared table is that a shared table is supervised by Enterprise Edition and it will be read-only unless it is checked out. An ordinary linked table will usually be read/write subject to the access controls of the host DBMS.
Project Capacity and Performance

When a component is shared to an Enterprise server, Manifold will upload a compressed version of the component into the Enterprise server. For large components, the process of compression can take a minute or more. When linking a component from an Enterprise server Manifold will fetch a local, read-only copy of the component into temporary local storage, decompressing it as it is fetched from the server. For large components, the decompression process can take a minute or more. Once a shared component has been linked into the project performance will be the same as if it were a local component.

Projects using shared components are subject to the same size limitation as other Manifold projects: for example, they cannot exceed a total capacity of 2 gigabytes. Enterprise servers can store as much information as can be handled by the host DBMS, possibly terabytes given the right hardware and software.

Compatible DBMS Products

Enterprise Edition has been developed using the latest editions of IBM DB2, Microsoft SQL Server (including SQL Server Express) and Oracle. These products are "supported" in that Enterprise Edition is designed to function using these three DBMS server products for Enterprise servers. Users purchasing Developer Tech Support incidents may ask questions about Enterprise Edition usage using those three DBMS servers as examples and may expect reasonably sensible answers.

Many other DBMS products may be used as Enterprise servers in addition to DB2, SQL Server and Oracle. For example, MySQL has been frequently used within manifold.net. Enterprise Edition even includes special code that works around a MySQL bug in a recent MySQL version that sometimes strips the last character in a stored section of binary data. There are many other fine DBMS products that will work well as Enterprise servers with Enterprise Edition. In general, any professional quality, multi-user, enterprise class DBMS that handles transactions well is a good candidate for use with Enterprise Edition. Some users even use Access 2000 (although this is discouraged since SQL Server Express is a profoundly better multi-user DBMS server).

MySQL users please note: Enterprise Edition requires that transactions support be enabled within MySQL when hosting an Enterprise server on MySQL. MySQL users should see the Manifold Knowledge Base articles on MySQL.

Enterprise Edition FAQ

Can I run Enterprise Edition without purchasing a DBMS system? Yes. You can install any of the three free DBMS packages and create Enterprise server databases within the DBMS installation thus created. You can also run Enterprise Edition without using Enterprise features (that is, like Professional) without any DBMS at all.

What is the best DBMS to use for an Enterprise Server? That depends upon the user's tastes and requirements. Each DBMS provided by Manifold is a superb, truly world-class DBMS, but all are different in various areas over which experienced DBMS administrators will passionately argue. Each DBMS has strengths in certain areas that would be a strong incentive for users interested in those strengths to choose that DBMS. See the Data Storage Strategies topic for a discussion. Users will often install and employ more than one of the three databases, although obviously there will be more to learn for the DBMS administrator if more than one system is used.

If we consider the limited question of just setting up a Manifold Enterprise server to use as a file cabinet without expectation of concurrent multi-user editing, then many users who are focused on capacity will install IBM DB2 Express-C Edition because it allows unlimited database size and will run using up to 4GB RAM and up to two processors. If maximum capacity in a free Express installation is the only consideration then clearly IBM DB2 Express-C has the edge.

But capacity as a Manifold Enterprise server using a free Express installation is not the only issue for many users. Many users will use mixed storage models where in addition to an Enterprise server they also want to use a classic geometry-storing centralized server to enable concurrent, multi-user editing of drawings or centralized storage of images. Or, they may have many existing applications that use Oracle or SQL Server. In that case, some other DBMS may be preferred. Any of the "big 3" DBMS packages may be used by Manifold as a spatial DBMS.

Users also may be considering the fit of the DBMS to their development environment. Organizations may realize their needs will far exceed the ability of even a very capable, free Express installation and may look to what DBMS they will eventually purchase in a full Enterprise configuration.
Even though Oracle Express does not include GeoRasters, other products from Oracle do, and once one expends the effort to learn how to be a DBMS administrator for a big-time DBMS there is a lot of wisdom to scaling up within the same vendor's product line. Users who are therefore just testing the waters with a free Express installation may well decide to go with Oracle even though the initial Express installation is limited in capacity to only 4 GB.

Finally, users who work with Microsoft programming in .NET or with Visual Studio will tend to favor SQL Server Express Edition despite the 4GB limitation on DBMS size because SQL Server Express is so tightly integrated with Windows development tools. Just as with Oracle, if users are using the Express edition to develop an application to be deployed on a much larger scale they will often choose SQL Server Express for development even though the ultimate application will require more than 4GB and will require a full license.

In all cases, when an organization's needs are so extensive that it is clear that the DBMS vendor's full DBMS product will be required it pays to have someone who really knows their DBMS technology examine the matter to make a decision which DBMS should be used. The three Express edition packages are a great starting point and a real testament to the power and competitiveness of these world-class DBMS vendors.

How is Enterprise Edition licensed? - See the License topic. Each computer on which Manifold System is installed must have a license for Manifold, except that for each license you may also install Manifold System on a notebook computer used by the primary licensee in addition to the main system used. You may install any of the three provided DBMS systems on any computer that will function as a server for Manifold. For example, you could have two Manifold licenses and thus operate Manifold on two different machines; however, you could also install SQL Server Express or DB2 Express-C or Oracle Express on several other machines to use as Enterprise servers. See the licenses within the installation packages for each of the three DBMS installations for details on allowed uses under the DBMS vendor's license.

Can I install IBM DB2, SQL Server or Oracle on a machine without installing Enterprise Edition? - Yes. You may install any of the DBMS packages provided on any machine you would like to configure as a server for Enterprise Edition or as a storage repository for tables for Professional Edition. You must use any such DBMS installation within the terms and conditions of the vendor's license that is packaged within the installation.

Does Enterprise Edition work with DBMS products other than the three supported? - Yes. It works with almost any DBMS that supports transactions and that has an ODBC driver. manifold.net has tested Enterprise Edition with Oracle, SQL Server and DB2 and will closely monitor these DBMS products as their vendors produce future editions. There are many other DBMS products with which Enterprise Edition will work; however, it is not possible for manifold.net to test them all or to keep track of new releases from all vendors.

Does Enterprise Edition read and write Oracle Spatial native formats? - Yes. See the Oracle Spatial Facilities topic. However, using Oracle spatial storage is a different thing than using an Enterprise server to store shared components. Using Enterprise Edition to set up Manifold Enterprise servers is a data storage model that shares the benefits of simpler, document-oriented storage models as well as the benefits of more complex, object-oriented server storage models.

Does Enterprise Edition read and write ArcSDE formats? - Yes, and ESRI Personal Geodatabase format as well. See the Spatial DBMS topic.

If more than five users attempt to work with SQL Server Express, will they lose data? - No. There is no longer a limitation to five users in SQL Server 2005 Express Edition as there used to be with the previous MSDE 2000 SQL Server Desktop Edition product. Even with the older MSDE 2000 product there would have been no loss of data, just much slower performance with more than five users.

Can I run Enterprise Edition with Windows 95? - No, and we sincerely hope that nobody ever tries. It is time to move on from early Windows editions and to install modern Windows editions like XP or Vista.

Can Enterprise Edition connect to an Enterprise server across Internet? - Yes. This is simply a matter of configuring the connection to the data source to work across Internet. Because Internet is normally slower than working in local area networks it is probably wise to retain the default cached storage option. There will then be some delay while fetching components initially from the server but thereafter work can proceed with local caching unless changes are made in shared components. That will greatly reduce the traffic passed back and forth over Internet.

Troubleshooting
To be sure your Enterprise Edition installation is working correctly, create an Enterprise server using SQL Server Express on the same machine, using an Administrator login for all work. The usual cause of any problems sharing components or otherwise using Enterprise servers are errors in the configuration or operation of the database server, or errors in the configuration or use of access permissions. It's the same familiar story well known to network and database administrators: one can configure a beautiful installation, but if a given user does not have access permissions to use it problems will occur. Ultimately, one cannot administer an Enterprise Edition administration if one does not know how to administer the host Windows operating system as well as the DBMS being used to host the Enterprise server.

Creating an Enterprise Server

Create an Enterprise server by creating a database in the database provider and then sharing a component into that database. This topic uses Microsoft SQL Server 2005 Express Edition as an example. Procedures for other database providers will be similar.

Creating an Enterprise server is easy:

- Create a new SQL Server database and set up the necessary permissions as described in SQL Server Express Edition.
- Create an ODBC data source to connect to that database. This can be done either within Manifold or using the Windows ODBC Data Sources applet in the Control Panel. (There is a shortcut to eliminate this step mentioned at the end of this topic.)
- Within Manifold, share at least one component into the new data source. Sharing the first component into the data source sets up the Enterprise server.

The lengthiest part of the process is creating a new ODBC data source. This involves stepping through several dialog pages. In the following example we create a new Enterprise server using SQL Server Enterprise Manager and Manifold.

Creating an Enterprise server database:

1. (Assuming an instance of SQL Server Express named SQLEXPRESS installed on a machine named MYSERVER.) Create a new SQL Server database named example and set up the necessary permissions as described in SQL Server Express Edition.
2. Log in to a machine that can access the database, using a user account with read and write permissions in the database.
3. Launch Manifold.
4. Create a blank drawing. Right click the drawing in the Project pane and select Share.
5. In the Share dialog, press the ... browse button to view available data sources. We will assume that no data sources have yet been created for the desired instance of SQL Server and will create a new data source.
6. In the Select Data Source dialog, switch to the Machine Data Source tab and click New.
7. In the Create New Data Source dialog, select User Data Source, click Next, then in the list of drivers select SQL Server, click Next, and finally click Finish.
8. In the Create a New Data Source to SQL Server dialog, set Name to something you can remember, for instance, Example Enterprise server, set Server to refer to MYSERVER\SQLEXPRESS, and click Next. Confirm that you will be connecting With Windows NT authentication using the network login ID and click Next. Check Change the default database to option and set the database to example, then click Next. Click Finish.
9. In the ODBC Microsoft SQL Server Setup dialog, click Test Data Source to make sure the data source works, then click OK twice.
10. In the Select Data Source dialog, select the newly created data source and click OK.
11. In the SQL Server Login dialog, confirm the choice of connection options and click OK.

(back in the Share dialog)

12. In the Share dialog, press OK. This will connect to the database, create the infrastructure tables for keeping track of shared components, and upload the drawing. The Project pane will show a "lock" icon near the drawing to indicate that it is now shared on an Enterprise server. If we save the project at this time, the component will be a shared component. Depending on whether we have caching turned on or off the cache will be saved locally. See theCached and Uncached Components topic for information on caching.

We have just created an Enterprise server that has one component in it. Note that everything in steps 6 through 11 was the routine Windows task of setting up a new ODBC data source. Creating a new SQL Server database was almost easier than creating a data source. Sharing a component (the actual Manifold part of the exercise) was very easy as well.
By definition, a new Enterprise server has at least one component in it. Once the Enterprise server is created we can Share (upload) more components into it and we can use those components in new projects.

Using an Enterprise server

1. Launch Manifold and open a project.
2. Choose Tools - Server Console to launch the Server Console dialog that allows browsing Enterprise servers.
3. In the Server box, the data source connection string that was last used will appear. Specify a new connection string manually or by clicking the [...] browse button. Press the Refresh button at any time to reconnect to the server and re-read its contents.
4. Click on the component desired and the toolbar buttons to Import or Link will be enabled.
5. Press Import to import the component into the project. This fetches a copy of the component from the Enterprise server into local project storage. Press Link to link the component into the project, leaving it stored within the Enterprise server and under control of the Enterprise server.

Components that have been linked from the Enterprise server into the current project will appear with a chain icon in the Server Console. They will also appear in the project pane with a lock icon when shared (that is, read only). Components in the project that are not provided by an Enterprise server will not have an icon. When the mouse moves over a component in the project pane a tool tip will read out the status of the component, such as the name of the user who has checked out the component.

If a component is checked out it can be deleted via the Server Console only by the user who has checked it out. If a component is not checked out it may be deleted by anyone via the Server Console. Components may be deleted, but they may not be renamed.

Folders

The New Folder button in the Server Console toolbar creates folders within the Enterprise server. Use folders to organize components within the Enterprise server and to keep the Enterprise server manageable.

This is especially important when Enterprise servers are very large and contain many components. Folders may be created anywhere within the tree hierarchy, and folders can be created within other folders. For example, we might have folders for countries, folders within those folders for provinces and then folders within those for different classes of information such as hydrography, transportation, boundaries and so on.

To move files between folders, drag components and drop them into a folder (drop them onto the folder icon itself and not the hierarchy beneath the folder). Folders may be created within other folders. If a folder is highlighted in the Enterprise server pane and the New Folder command is issued, the new folder will be created within the highlighted folder. Folders may be dragged and dropped into other folders. To move a folder out from within another folder, drag it and drop it into the "white space" of the Enterprise server outside another folder. Folders may not be renamed, but they may be deleted. To delete a folder that contains components the components involved must be checked out.

There is no limit on the number of folders within an Enterprise server, but the number of components within a single folder is limited to approximately 1000 components. As a practical matter, if one is working with such a large number of components it is wise to organize them within subfolders.

Simplified Syntax for SQL Server Connections

Enterprise dialogs allow a simplified connection string syntax for SQL Server databases as an option to full ODBC syntax. \\
connects to the specified database on the given system. \systemname:database\ connects to the default database on the given system. The connection established with a simplified connection string that uses Windows integrated security (suitable for users working in Windows Server 2003, Windows XP and Windows 2000). Using simplified connection strings is a fast way to connect to SQL Server or to SQL Server Express using default options without dealing with the ODBC dialogs.

For example, if we have installed SQL Server on a system called PROJECTS and we have created a database called hydrography to use as our Enterprise server database, we could connect in the Server Console by entering \projects\hydrography into the Server box of the Server Console and then pressing the Refresh button.
SQL Server Express

Microsoft provides free download of a complete installation package for Microsoft's SQL Server Express, the same engine that powers SQL Server. Installing SQL Server Express allows high performance, centralized DBMS storage via Enterprise servers using SQL Server capabilities without any additional purchase required. See the SQL Server Express Edition topic for more.

Connection String Security

When Manifold saves the last used connection string in between Manifold sessions, the connection string is stored in encrypted form. This security measure prevents intruders from learning your connection strings by attacking the Windows registry or other commonly available resources.

Some connection strings to connect to Enterprise servers may use passwords in PWD entries within the connection string. For additional security, Enterprise dialogs conceal passwords that occur within connection strings by replacing the password’s characters with * asterisks. See your ODBC documentation to learn about connection strings and PWD entries in connection strings.

When a user enters a connection string containing a password and presses the Refresh button Manifold analyzes the connection string to identify the password, saves the password in encrypted form in internal memory and then substitutes the password with asterisks in the edit box so that the password does not appear in plain text.

If the user later modifies the connection string (say, by changing the name of the server) and presses Refresh, Manifold knows to use the internal, saved password in place of the asterisks when connecting to the data source. If the user modifies the connection string so that it no longer contains a PWD entry, no password is used. If the user modifies the content of the PWD entry to some value that does not entirely consist of asterisks, the system will accept the new value as the new password. The above works with the Browse button as well.

Notes

The simplified syntax available for SQL Server connections means that we really did not need to create an ODBC connection to work with an Enterprise server hosted on SQL Server as set forth in the beginning of this topic. After creating a database in SQL Server using the SQL Server Enterprise Manager and granting users the desired permissions, we could have shared the component by simply entering \systemname:example into the Share on box when we shared the first component into the Enterprise server. After that, we could enter \systemname:example into the Server box of the Server Console to work with that Enterprise server.

Using simplified syntax is somewhat easier than configuring an ODBC source as described in this topic, but it only works with SQL Server. This topic set forth the full procedure to illustrate how ODBC sources can be configured from the browse button in the Share dialog, to provide an example that may be more useful when using databases other than SQL Server which require configuration of an ODBC source.

The short examples given above show one database created within SQL Server. We could create many databases within each SQL Server installation and use them all simultaneously. Each database is used as a separate Enterprise server.

For example, suppose on the machine called PROJECTS we install SQL Server and then create databases called hydrography, boundaries, transportation and utilities. We could work with each of these in the Server Console as four different Enterprise servers using the shorthand connection syntax of \projects:hydrography, \projects:boundaries, \projects:transportation and \projects:utilities. We could include shared components from each of these in the same project.

Working with Enterprise Edition
Cached and Uncached Components
Working with Enterprise Edition

Setting aside the creation of Enterprise server databases and the ODBC data sources used to connect to them, working with Manifold System Enterprise Edition is very similar to Manifold System Professional Edition.

There are two key dialogs used for interactions with Enterprise servers:

- The Tools - Server Console dialog shows a catalog of components available within a given Enterprise server. Use the Server Console to import or link components from an Enterprise server. The Server Console is also used to organize Enterprise servers by creating folders within the server and arranging components within those folders. Use the Server Console to delete components from the Enterprise server. Deleting a component will also remove all maps containing it as a layer.

- The project pane shows components in the current project just as it does in Manifold System Professional Edition. Right click onto a shared component to Get Latest Version, Check Out, Undo Check Out or Check In an existing remote component or to use Share to upload a component to the Enterprise server.

Adding Components to an Enterprise Server

To add components to an Enterprise server, right click on a component in the project pane and choose Share. The process is called sharing a component to the server. The component will be uploaded to the Enterprise server and will appear in the project as a shared, read-only component. Sharing a component will share all dependent components as well. For example, if we share a map to an Enterprise server all of the components that are layers in the map will also be shared to that server.

When sharing a component to the server the component is uploaded to the Enterprise server in compressed form, growing the storage requirements of the Enterprise server by the compressed size of the component. Compression achieved by Enterprise servers will vary depending on the component with typical compression factors achieved being those similar to compression achieved by "zip" utilities, the same as if the components were saved in a compressed .map project file.

Sharing a subsidiary component to an Enterprise server will also share the parent component to the Enterprise server. For example, sharing a terrain or a profile will also share the terrain's or the profile's parent surface as well. Sharing an elevation will also share the elevation's profile and the profile's surface as well.

Removing Components from an Enterprise Server

Use the Server Console to remove components from an Enterprise server. Click on a component to highlight it and then press the Remove button. We cannot remove a component that is checked out. If a component is linked into a project removing it from the server will also remove it from the project.

Removing a component from the server will remove all components in our project that are bound to that component. For example, removing a map from the server will remove the map, but will leave components that were constituent layers of the map (the map depends on the layers but not vice versa). On the other hand, removing a component will remove any map from the server that contains that component as a layer. Removing a drawing will also remove the drawing's table and vice versa because a drawing and the drawing's table are inextricably bound to each other.

Getting Shared Components

Components may be imported from any of the file formats supported by Manifold. They may also be imported or linked from an Enterprise server by using either the File - Import or File - Link commands or via the Tools - Server Console dialog.

When a remote component is linked into the current project it appears in the project pane with a "lock" icon to show it is a shared component that is read-only. If it is opened, it may be viewed or participate in a map but it cannot be modified in any way. If we open it in a window the format toolbar, the selection toolbar and other editing toolbars will not be enabled.

Modifying a Shared Component
To modify a shared component we right click on it and choose Check Out. When a component is checked out it may be modified. All toolbars will be enabled for that component. As long as we have a component checked out from an Enterprise server, no other user can check out that component. Another user can get it by linking it into their project, but they cannot check it out to make modifications until we check it back into the server. When done modifying a component we should right click on it and Check In. This will upload the changes to the server and make the component a read-only shared component.

If we would like to abandon any modifications made, we right click on a component and choose Undo Check Out. This abandons any changes and gets the latest version of the component from the server. Checked out components cannot be deleted from a project pane. To delete a checked out component, either check it in or undo the check out and then delete it.

Manifold tries to provide the greatest range of modifications possible in a component without checking out dependent components. This adds flexibility at the cost of requiring some additional thought. For example, if we check out a drawing we will be able to format that drawing but we will not be able to add new objects (points, lines, areas) unless we also check out the drawing’s table.

Note that if another user has already checked out a component that we wish to modify we will not be able to Check Out the component. We will have to wait until that other user has checked it back in.

When exiting Manifold or closing a project, the system will remind us if we have any shared components that are still checked out. It is possible to close Manifold while a component is still checked out. We may want to keep a component checked out until the next time we are able to work with Manifold because we have not yet finished modifying it.

**Getting Changes**

If someone else checks out a shared component we will not see any modifications they make until they check it in and we choose Get Latest Version. This will update the component in our project with the latest version from the Enterprise server.

**Working with Maps**

Maps may be shared to an Enterprise server subject to the following conditions:

- A shared map can only contain layers from the same Enterprise server on which it is shared.
- Adding an existing layer to a shared map requires that the existing layer a) is shared on the same Enterprise server with the map and b) is checked out.

Important: components not fulfilling the above criteria are not shown in the Add Existing Layer dialog and will refuse to drop into a map when dragged from the Project pane.

- Removing existing layers from a shared map does not require anything except that the map itself must be checked out,
- Adding new layers to a shared map is not allowed.
- Local maps can contain both local components and shared components (possibly from different servers).
- Removing a shared drawing, image, labels or surface component from a project will remove all shared maps containing it as a layer.

**Sharing Linked Images**

Sharing a linked image to an Enterprise server places the linking information into the Enterprise server and not the actual image data. Importing or linking such a shared linked image to a local project will re-establish the connection to the relevant file or server. See the Linked Images topic.

**Miscellaneous Dependencies**
Because shared components are usually read-only, numerous dependencies arise between components that are related to other components. Non-trivial dependencies that will become apparent as a result of automatic disabling of menus and toolbar buttons include:

- Adding or removing objects in a shared drawing requires checking out both the drawing and the table bound to the drawing (which is also shared). Since most drawing transforms either create or remove objects, they also require checking out both the drawing and the drawing's table. Editing objects in a shared drawing using visual editing tools (so long as objects are modified but not added or removed) requires checking out the drawing, but not the table.
- The Transfer Selection dialog does not allow transferring a selection to shared components that have not been checked out.
- Removing records from a table bound to a shared drawing (hence also shared) is similar to removing objects from that drawing and requires checking out both the table and the drawing it is bound to.
- Removing a table column used in drawing formatting (assuming both the drawing and the table are shared) requires checking out both table and drawing.
- Adding a relation to a shared table can only go to a table shared on the same Enterprise server and requires checking out both tables. The Add Relation dialog launched on a shared table hides local tables and tables shared on other Enterprise servers. The Add Relation dialog launched on a local table hides all shared tables.
- Shared components cannot be renamed.
- To preserve naming consistency, remote components cannot be linked into a project if they have the same name as a local component already in the project. Likewise, a local component cannot be shared to an Enterprise server if the server already has a remote component of the same name. Rename components as necessary to make room for like-named components that are to be linked or shared.
- A shared map does not allow dragging layer tabs to new positions unless it is checked out.
- Unsharing a component that "owns" other component unshares all owned components. For example, unsharing a drawing also unshares its table, any scripts bound to the table and any labels bound to the drawing. Similarly, unsharing a component that "is referred to" by other components unshares all referring components. For example, unsharing a drawing also unshares any maps containing the drawing as a layer, any tables linked to the drawing's table with relations, any components owned by such tables (such as scripts) and so on.

Relations and Shared Tables

For advanced users, it may be useful to consider how relations between shared tables can and cannot be formed.

Manifold can establish a relation between an ordinary table and a linked table, between two linked tables, between two shared tables located on the same Enterprise server, but not between an ordinary table and a shared table, or between two shared tables located on different Enterprise servers.

Let's do a thought experiment to consider what could happen if a relation between an ordinary table and a shared table were allowed. Suppose we check out a shared table, create a relation between this shared table and an ordinary table, bring some columns from the ordinary table into the shared table, and then check in the shared table. We then go to another machine and bring the shared table into a new project. On the new machine, Manifold will not be able to display the data in the columns brought in from the ordinary table we used on the first machine, since that table is not in the project we created on the second machine.

Even if the project on the second machine happens to contain a table with the same name as the ordinary table on the first machine, there is no guarantee that the shared table will display the same data on the first and second machines. To guard against situations like this we cannot form a relation between an ordinary table and a shared table.

If it was possible to create a relation between two shared tables located on different Enterprise servers we could encounter similar problems. If this were allowed there would be nothing stopping us from linking to the first table, but not to the second table, and creating a situation where the first table would not have any way to display data from the second table. Note that this is different from the case where both tables are on the same Enterprise server, since in that case the system will automatically link in the second table if we attempt to link to the first table.

Saving Projects - Cached Components

Enterprise projects are saved in the usual way. Components may be saved as cached or as uncached components. When the project is opened again the links to the Enterprise server will be automatically re-established if the project is opened on the same system, where the same connection string to the ODBC data
source representing the Enterprise server can work. See the Cached and Uncached Components topic for additional information.

When saving a project that contains a cached checked out component, that component will remain checked out until that project is opened again and the component checked in. To see how this works, check out a component and then save the project and close Manifold. Launch Manifold again and link the component from the Enterprise server into the new project. It will be reported as checked out by some other user because it is still checked out in the previous project that was saved.

This is good, because it allows people to take breaks while reserving the component and their current work state by leaving it checked out. In fact, one can check out a component and save the project and then open a second project and link the component from the server into that second project. In the saved project the component is checked out. In the new, open project the component is shown as checked out by another user.

This, too, is sensible because we may be working with the same component in several different projects at the same time. We might be in the middle of editing it in one project yet have to set aside our work temporarily to work on a different project that also uses that component. When we set aside our editing session we can save the project with the component in a checked out state. When we open another project that also uses that component it will appear in the project as checked out by another user. The component will be seen in the project pane with a dark lock icon, the usual icon showing it is checked out by a different user (the tool tip info will show it is checked out by us).

When we open the Server Console it will show components that are checked out by us in different projects with a red link icon. This is to remind us that we have some components checked out in projects other than the one on which we are currently working.

It could well be that we check out a component, save the project, set aside our work and then later forget we have saved the project with a checked out component. It might happen that when we see the red link icon for a component in the Server Console we won't remember in which project .map file it has been saved in a checked out state, or even whether or not we have deleted the .map file in which it was saved in a checked out state. At such times we can use the Undo Check Out button in the Server Console to undo the check out status of that component. This command will reset the state of the component on the Enterprise server to checked in. The next time the project containing the component in a checked out state is opened or refreshed, Manifold will automatically execute an Undo Check Out on that component in the project state and will cause any changes made since the last check in to be discarded.

Users with experience participating in large teams will predict that some users may check out a component and then depart for vacation or otherwise instill a desire in Administrators to forcibly rollback a checkout for a component that the server shows is checked out in someone’s project. Undoing check outs made by users other than the current user is unsafe and should be done only by the DB administrator. See the Administering Enterprise Servers topic for notes on forced rollback (undo check out) of components checked out by someone else.

Note that we cannot Close a project if it contains checked out components that have been checked out since the last save.

Saving Projects - Uncached Components

Saving projects that contain uncached components is the same as saving projects with cached components, except that in the case of uncached components we cannot save a project that contains checked out components. The reason is simple: since an uncached component is always reloaded from the Enterprise server when a project is opened, it makes no sense to save a partially edited version that will be replaced the moment the project is reopened. Likewise, one cannot Close a project that contains a checked out, uncached component.

Capacity

Enterprise projects are limited to a maximum of 2 gigabytes of components in uncompressed form. There is no limit to the number of components that may be saved on the Enterprise server except for whatever capacity limitations are imposed by the database provider used to host the Enterprise server.

Security
User access permissions in Enterprise Edition are set by the user access permissions applicable to the database that hosts the Enterprise server. Most database management systems, such as SQL Server, have numerous options for database security in combination with the operating system security model as well as various hierarchical rules controlling propagation of permissions between different database objects. It is therefore essential to understand thoroughly the Windows security model as well as the security model used by the database system.

**Project Pane Updates**

By default, Manifold will contact the Enterprise server every 120 seconds to see if any shared components have been checked out or checked back in by another user, updating the status icons in the project pane accordingly. This automatic refresh may be disabled in **Tools - Options - Server Storage** by unchecking the **Refresh state of shared components** box. The refresh time may also be set to a value different than 120 seconds.

**Tech Tip**

We would often like to save comments with a shared component on the Enterprise server so that whenever someone gets the component they will automatically get our comments with it. This can be done by saving any notes desired into the **Description** box of a component's **Properties** dialog.

**Notes**

Why must an existing layer be checked out if it is to be added to a shared map? The existing layer must be checked out to protect against the following scenario:

- An Enterprise server contains map M and drawings D1, D2 and D3. Drawings D1 and D2 are layers of M and all components are checked-in.
- User U1 check outs M and adds D3 to the map,
- User U2 deletes D3 from the server,
- User U1 checks in M, which is now invalid.
Cached and Uncached Components

This topic applies to Enterprise Edition only. If you have not installed Enterprise Edition you will not be able to use the features discussed.

When working with Enterprise Edition we will normally want to save our work in a project by saving the project to a .map file in the usual way. Enterprise Edition has two modes in which shared components can be saved when a project is saved to a .map file. Shared components can be cached or uncached for the purpose of saving projects.

- **Cached components** - When a component is marked Cached the Enterprise cache for that component will be written into the .map project file when the project is saved. This will grow the .map file by the size of the cached component.

- **Uncached components** - When a component is not marked Cached the Enterprise cache for that component will not be written into the .map file. Instead, only a link to the shared component on the Enterprise server for that component will be saved.

Shared components are cached by default. We can designate a component to be uncached by right clicking on a shared component in the project pane and choosingCached from the pop-up context menu to toggle the check mark next to the Cached entry. Tool tips and the project pane status bar will show the cached/uncached status of each shared component.

The word "cache" is a computer term that refers to use of local memory that may be rapidly accessed. When Manifold first links a shared component into a project from an Enterprise server it fetches the component from the server into an Enterprise cache maintained in local memory, both in RAM and in temp files on local disk. The Enterprise cache always contains a snapshot of all components with which we are working whether they are shared or local. The Enterprise cache allows operations in local memory whenever possible to greatly reduce transactions with the Enterprise server. This increases speed because it greatly reduces the interactions between the client and the server, so our desktop (the client) is not slowed down by bottlenecks at the server.

When we save a project, Manifold checks the Cached status of each shared component in the project. If the Cached setting is checked, the Enterprise cache for that component will be saved into the .map project file that is created when the project is saved. As a practical matter, saving the Enterprise cache into the project for a component is equivalent to saving a controlled copy of the component into the project’s .map file. Doing so will grow the .map file by the size of the component.

If the shared component is uncached, that is, the Cached setting is not checked, then the project’s .map file will contain only a link back to the remote component on the Enterprise server. Saving a project that contains uncached, shared components saves no data from shared component within the project’s .map file, so it will not grow the size of the .map file by the size of the component.

In both cases, regardless of whether a shared component is cached or uncached, the Enterprise status of the shared component will be preserved when the project is next opened. For example, suppose we create a new project, link into it several shared components, check out one of those components and save the project. We could close Manifold, go away for lunch, come back later and open the project and the component will still be checked out. This will be true whether or not the components were cached or uncached.

Advantages and Disadvantages

Some readers may wonder: If checking the Cached setting for a shared component causes a copy of it to be saved within the .map file, doesn’t that defeat the purpose of an Enterprise server? That is only so if one imagines the purpose of an Enterprise server to be limited to saving disk space. In an era of essentially free disk storage capacity (due to the very large sizes of modern disk drives and their very low costs), the greatest benefit of centralized storage on an Enterprise server is not saving disk space, it is making work more efficient by allowing collaborative efforts within teams and by providing centralized archives and version control.

Caching components and saving them to project files does not interfere in any way with the component discipline implied by Enterprise Edition’s sharing, check out and check in procedures. The client side of Enterprise Edition will enforce all dependencies just as if components were not cached. Caching allows faster client startup, more efficient server operation and greater operational flexibility and safety.

Caching allows greater performance when a project is opened because the constituents of that project need not be fetched from the Enterprise server. When a project consists of large components the time required for decompressing and fetching a component from the Enterprise server could be a long time even if no one else is
trying to fetch components from the server at the same time. Caching components reduces the need to interact with the Enterprise server to only those times when components are changed.

Advantages of Cached Components

- Reduces load on the Enterprise server, allowing the same system to serve more users.
- Faster opening of projects when the Enterprise server is loaded by other user requests at the same time, such as at the beginning of a business day when many users at once may launch projects that fetch data from an Enterprise server.
- Work can continue on projects when the Enterprise server is inaccessible. For example, one could begin a project on a notebook computer connected to a local area network, save the project and then continue working with the project while travelling on an airplane.
- Reduced latency allows working with larger projects if the Enterprise server is accessed over an Intranet or the Internet.
- Automatic redundancy safeguards important data. If the Enterprise server crashes we will not lose any data if a project has been saved with cached components.
- Professional Edition can transparently handle cached shared components, so it can open a saved Enterprise project if it includes only local and cached shared components. This allows easy data and project interchange between a work group that includes both Enterprise and Professional users.
- Data exchange becomes simpler, because one can send a .map file that contains cached components to another user. Even if the Enterprise server cannot be contacted at least the components will be available in their last-saved state.
- Projects using cached components can be saved with cached components in a checked out state. This allows checking out a component, performing some edits and then setting the work aside in a saved project to be finished at a later time.

Disadvantages of Cached Components

- Cached components require more disk space when projects are saved, because each saved project contains the Enterprise cache image of the cached shared component.
- When a project is opened users must get the latest version of components that have been changed by other users since the project was last opened.

Advantages of Uncached Components

- Opening a project automatically gets the latest version of all uncached components. Because uncached components are fetched in their entirety every time a project is opened they are automatically up to date.
- If many common files are in use throughout an organization, not caching components will assure that only one copy's worth of disk space is used for a shared component throughout an organization: the space required on the Enterprise server for that component.

Disadvantages of Uncached Components

- Uncached components exist in only one location: the Enterprise server. If a connection to the server cannot be established or if the server crashes the components will be deleted from the project. It is therefore essential to establish and maintain a backup regime to backup the database on a regular basis. However, setting up automatic backup of databases is often a chore neglected by the experienced administrator and beyond the skill set of a novice.
- Delays caused during "rush hour" in the morning or at the end of a work day can lead to user complaints, since few organizations scale their hardware to provide acceptable performance during peak loads. Because disk space is a lot cheaper than system throughput it is far cheaper and easier to deploy slightly larger hard disks for user desktops than it is to scale a central server to handle huge loads that appear for only a fraction of the work day.
- Professional Edition users cannot use projects containing uncached components.
- The need to fetch uncached components every time the project is open will limit the size of projects that are practical to share via Internet.
- Data exchange becomes more complicated because it is generally not possible to simply exchange .map files, since the connection strings to the Enterprise server will not likely be the same for a different user. If we send a .map file containing shared components to someone else they will not be able to see or use the shared components unless they are able to use exactly the same connection string to connect to the data source for that Enterprise server. This is highly unlikely unless both users are working on the same machine.
Projects containing uncached components cannot be saved if any of the uncached components is checked out. This means that all desired edits must be accomplished and the component checked in before the project is saved.

From the points above it can be seen that the main benefit of using uncached components is a reduction in disk space used when the same component appears in many projects. For a single user working with many projects this can be a worthwhile savings, since a single user will be working with only one project at a time.

However, if the objective is to reduce disk space because many users have included the same shared component in their projects the tradeoff is not so simple. In this case, the reduction in disk storage comes at the cost of a dramatic increase in transactions with the Enterprise server when many users open their projects and thus a greatly increased peak-processing requirement during busy times of the day.

If components are uncached, one must invest in a reliable, fast machine to host the Enterprise server. It must be reliable because if it fails our data disappears. It must be fast because multiple user demands will be more likely when every time a project is opened every uncached component must be loaded from the server.

In contrast, if we are willing to take advantage of large, cheap hard disks and use cached components we can use a relatively inexpensive machine for our Enterprise server that need not be particularly fast. User accesses to the Enterprise server will rarely happen simultaneously because components will be read or written only when they are changed. The great majority of projects will load shared components only when they are first created. Thereafter, user load will be negligible since the server is consulted only in brief contacts to check the status of components. On occasion when a component is changed there will be some activity as a new version of a component is checked in and other users get the latest version.

Of course, one can use a mix of cached and uncached components in a project to balance the advantages and disadvantages of caching in a particular project.

Default Settings

In Tools - Options - Server Storage the Cache newly shared components option specifies whether newly shared components will be cached or uncached. By default, this option is checked so that newly shared components are cached. If this option is not checked, newly shared components will be uncached.

Notes

When working with uncached components Manifold will load the uncached components when a project is opened; however, it also most load the uncached component from the Enterprise server once more after saving a project. Both operations are internal and are transparent to the user except for the time required to fetch an uncached component from the Enterprise server. Users will normally expect a delay while components are fetched from the Enterprise server when a project is opened; however, a similar delay when saving a project may come as a surprise. However, the re-load of cached components upon a project save is required to maintain cache synchronization.

Working with Enterprise Edition
Administering Enterprise Servers
Administering Enterprise Servers

Enterprise servers used with Enterprise Edition are based on the host database, so routine administration of Enterprise servers mainly consists of the usual tasks involved in administering the host database. For information on administering your host database (backups and similar tasks) see the documentation provided by your database vendor. This topic discusses issues specific to the interplay of Enterprise servers and saved projects.

Checked Out Components

The main administrative issue arising when working with Enterprise servers occurs when one user has checked out a component that another user wishes to edit. If one user has checked out a component for editing no other user can edit the component until it is checked back in. If both users are online at the same time the situation is simple to resolve - the user who wants the component emails, instant messages or calls the user who has it checked out and asks that the component be checked back in.

Saved Projects and Cached Components

A more complex scenario emerges if a user checks out a cached component, saves the project and then the component needs to be used for editing. This situation usually occurs in three forms.

- The same user has checked the component out and saved it in one project file, but needs to edit it in another project file. In this case, the user can open the Server Console and use Undo Check Out to undo the check out. This will show the component as checked in on the server and will abandon any edits to the component that may have been made in the project where it was checked out. This works even in cases where the user cannot remember in which project file the checked out component can be saved.

- One user has checked out a component and saved it in a project file but another user needs to check out the component. In this case, if the user with the checked out component can be located other users must negotiate with him or her to get the needed component checked back in.

- At times users will check out cached components, save them in a project and then become unavailable, perhaps going off on vacation or departing the organization. In such cases a database administrator will have to do a forced rollback of the component check out.

Undo Check Out compared to Check In

The Undo Check Out command is not the same as a Check In command. When a component is checked out if it is checked in any edits made while it was checked out will be saved to the component. When an Undo Check Out is done, any edits made while it was checked out will be abandoned.

Forced Rollbacks

Undoing a check out is also called a rollback. Users can undo a check out for components they themselves have checked out by using the Server Console’s Undo Check Out command. This command will mark the component as checked in on the server so that the project can update itself the next time it is refreshed. Projects are refreshed whenever:

- The project is opened.
- The user presses the Refresh button on the project pane toolbar.
- The refresh timeout interval specified in Tools - Options passes.

A more complex situation arises when an administrator must undo a check out for a component when a user who checked out that component is not available to use Undo Check Out in the Server Console. In that case, a manual Undo Check Out must be performed within the Enterprise server’s database structure. This is done by manually opening the Enterprise server database and editing fields within the database tables using whatever tool is normally used to make edits to the database.

To force a rollback of a component in an Enterprise server:
1. Using a suitable tool, connect to the database containing the Enterprise server.
2. Open the mfd_root table.
3. In the mfd_name field, find the names of the components for which check out is to be undone. Each component will be one record.
4. For each such record, change the values of the mfd_user and mfd_user_info fields to either blank strings or NULLs.
5. Commit changes.

Very important: Make sure not to edit the system record by accident. This record has "system" in the mfd_type field.

Note that the above procedure requires the ability and skill set to be able to open database tables and to edit them. Most DBMS products used as Enterprise servers will have such interactive tools. If a system such as SQL Server Express is used that does not provide interactive tools, one can always link the mfd_root table into a Manifold project using File - Link - Table (OLE DB) and then browse the table and make changes to the mfd_user and mfd_user_info fields in the linked table. Note that OLE DB drivers for most databases do not show a dynamic view of tables: they only show the tables at the moment the connection was made. To see the results of edits, therefore, one must either do a View - Refresh or close the connection and reconnect.

Orphaned Check Outs

An orphaned check out occurs if a component has been checked out on an Enterprise server without being checked out in a project. This happens in two cases:

- A user checks out a cached component and saves it in a project. Later on the user deletes the project file, either by accident or deliberately (forgetting it contains a saved, checked out component).
- A user checks out a component while working on a project when a crash occurs before the project can be saved or the component checked in. This might happen during an electrical power failure or other unexpected crash.

Orphaned check outs are easily resolved by the user launching Manifold, opening the Server Console and issuing an Undo Check Out command for the component. If the user who has an orphaned check out is no longer available, the database administrator can follow the procedure noted above for a forced rollback.

Cheap Insurance

As with any centralized DBMS, if the Enterprise server database is damaged the data it contains can be lost. It is very important to use a robust DBMS within a robust operating system that is hosted on reliable hardware. The following tips will increase reliability of Enterprise servers:

- Choose a reliable DBMS. Use a real DBMS with reliable transaction capabilities. For example, although Access 2000 is said to work with Enterprise Edition it is a poor choice because of its relatively lower reliability in multi-user environments. Use SQL Server Express instead. It is a free download from Microsoft. SQL Server Express has the full reliability of SQL Server in multi-user environments.
- Use Windows 7 or Server 2008. Both of these systems are so much more reliable than earlier Windows editions that they should be your only choices for server applications.
- Choose reliable hardware. Insist on a high quality motherboard for the server and run it conservatively (avoid overclocking processors and other "hot rod" alterations). Consider choosing a motherboard with built-in hardware RAID so that two identical disk drives can be installed for a hardware mirror. If one disk drive fails, the other will enable continued operation until a second drive can be installed.
- Install service packs and other updates when they are issued by the DBMS vendor and Microsoft. Install the latest service packs for Manifold as well.
- Install lots of RAM memory. Working with many users in complex DBMS products with small amounts of RAM is a great way to find previously undiscovered bugs in DBMS products.
- Configure the DBMS for automatic backup to another computer system on the local area network. Systems like SQL Server can be configured to automatically save a backup to a different location.
- Install an uninterruptable power supply (UPS) to power your server through unexpected electrical power outages and to shut down the server down if the power outage continues past the reserve power of the UPS.

Troubleshooting
To be sure your Enterprise Edition installation is working correctly, create an Enterprise server using SQL Server Express on the same machine, using an Administrator login for all work. The usual cause of any problems sharing components or otherwise using Enterprise servers are errors in the configuration or operation of the database server, or errors in the configuration or use of access permissions. It's the same familiar story well known to network and database administrators: one can configure a beautiful installation, but if a given user does not have access permissions to use it problems will occur. Ultimately, one cannot administer an Enterprise Edition administration if one does not know how to administer the host Windows operating system as well as the DBMS being used to host the Enterprise server.
Database Administrator Edition

Database Administrator Edition

Manifold System **Database Administrator Edition** is a version of Manifold System that includes additional capabilities for setting up and managing GIS data storage in DBMS systems not found in other editions. If you have purchased and installed Database Administrator Edition the features described in this topic as well as in the Tools - Administrator Console topic and the Tools - Batch Export topic will be available to you. Database Administrator Edition is also included within **Ultimate Edition**. If you have installed some Manifold System edition other than Database Administrator or Ultimate editions you will not be able to use these features.

Database Administrator Edition is a superset of Enterprise Edition and includes all features found in **Enterprise Edition**. In addition, Database Administrator Edition includes a powerful managerial console called the Administrator Console that enables IT and DBMS administrators to configure data sources used to store the enterprise's geospatial data. The Administrator Console allows administrators to configure GIS data storage within the data source so that the data source is easier and more convenient to use for ordinary GIS users.

Database Administrator Edition also includes the Tools - Batch Export tool that facilitates rapid, mass uploading of Manifold drawings, images and surfaces into Oracle spatial databases. Upload of drawings requires an Oracle database server with Oracle SDO_GEOMETRY capability. Upload of images and surfaces requires an Oracle database server that supports Oracle GeoRaster capability. Oracle Spatial supports both types. Note that Oracle Express Edition supports SDO_GEOMETRY but not GeoRasters.

The intent of Database Administrator Edition is to make it easier for organizations to concentrate the expertise they have available for DBMS and IT administration, so that relatively few expert users can make it possible for relatively many, less expert users to take advantage of the power of geospatial data centralization within enterprise-class DBMS storage.

**Licensing**

Organizations that store their geospatial data within databases will acquire Database Administrator Edition licenses for their IT and DBMS administrators in addition to however many Enterprise Edition or Universal Edition licenses they acquire for other users. The administrator will use Database Administrator Edition to set up the DBMS for more convenient use by ordinary users, for example, by setting up friendly names or by enabling the storage of formatting for drawings as well as geometry and attributes.

Once Database Administrator Edition is used to configure a database with user-friendly features, any Manifold edition connecting to that database (such as Enterprise Edition or Universal Edition) can utilize those features. Manifold editions other than Database Administrator Edition that connect to the database will not be able to override or alter the settings specified using Database Administrator Edition. This assures that expert configuration by administrators will not be altered into chaos by inexpert users.

Although a typical large organization might have a few dozen Database Administrator Edition licenses with many hundreds of Enterprise Edition licenses, some organizations will have a higher ratio of Database Administrator Edition licenses if the organization has a higher percentage of users with the skills and administrative responsibilities to be trusted with administrator functions. For example, a very small organization such as a consultancy with a staff of five professionals, each of whom has great expertise and is trusted by his or her peers with DBMS administrative rights, might simply install Database Administrator Edition licenses for all five professionals. Each professional could then manage the DBMS as necessary, for example, uploading drawings and then right away configuring the data store for subsequent employment by his or her peers.

Conversely, an organization with relatively few administrators and many inexpert users will want to centralize all management of their data store within those few administrators and will therefore procure a relatively lower ratio of Database Administrator Edition licenses compared to the bulk of Enterprise Edition or Universal Edition licenses procured for ordinary users.

**Benefits for Manifold System Users**

Although the server statistics reporting capability of Administrator Console will prove useful in any environment, the client benefits of Database Administrator Edition such as friendly names will extend only to subsequent usage by Manifold System users and not to users of other GIS software. Legacy GIS software from other vendors does not in general have the capabilities of Manifold so the benefits of enhanced capability or user-friendly features made possible by Database Administrator Edition will not be available outside of Manifold System.
However, the client benefits of Database Administrator Edition are provided in a neutral way so that if a particular data storage method is used, such as SDO_GEOMETRY in Oracle Spatial, that supports multi-vendor interoperability then such interoperability will be preserved. Database Administrator Edition provides enhancements for the benefit of Manifold System users without interfering with least common denominator interoperability for users of other software.

In fact, Database Administrator Edition even allows DBMS administrators to identify some types of legacy storage, for example, using "open" binary geometry storage formats such as OGC WKB, as drawings that can be enrolled within Manifold user-friendly views. This allows Manifold users to still enjoy extended capabilities and user-friendly features even if the original data store was loaded from a legacy GIS system.

**Workflow**

DBMS administrators will normally employ Database Administrator Edition in the following workflow for each component uploaded to the data source in use:

1. Prepare the component for upload. For example, when exporting a drawing that is to be used for versioned edition to a non-Oracle DBMS we will have to create a version column. When exporting a drawing containing multiple variable-length columns to Oracle we will have to convert some of those columns to fixed length so that the drawing does not exceed the Oracle limit of one variable-length column per table.

2. If we are working with an Oracle database we can upload the component to the DBMS using the Tools - Batch Export command to export many components at once to Oracle. If the DBMS is not Oracle, we can export a drawing by exporting the drawing’s table using File - Export and including the Geom (I) column as is shown in the Storing Drawings in SQL Server example topic.

3. Using Administrator Console, specify a friendly name to be used for that component.

4. Using Administrator Console, enable formatting, if desired, for drawings.

5. Using Administrator Console, specify link and import options for the component, for example, such as the version column to be used for versioned editing.

Step 1 above is accomplished using Manifold tools such as capabilities in Tables that allow adding new columns and changing column types.

Step 2 above is normally accomplished using File - Export dialogs or the Batch Export tool if an Oracle database is being used.

Steps 3, 4 and 5 are accomplished using the Administrator Console that is provided within Database Administrator Edition.

See the Using Administrator Console topic for details and examples on how the above workflow is accomplished using the Administrator Console. See the Tools - Batch Export topic for details on using Batch Export.

In addition to the above cycle for each component uploaded, the administrator will of course still manage the host DBMS in the usual way using whatever tools are provided for that DBMS. For example, administrators will create databases, create user logins and assign user roles and so forth. Such activity is DBMS-specific and will be accomplished using the administrative tools provided by the DBMS vendor.

Using Administrator Console

This topic describes a feature that is provided only within Manifold Database Administrator Edition and is not available in other Manifold System editions. If you have purchased and installed Database Administrator Edition the features described in this topic will be available to you. If you have installed some other Manifold System edition you will not be able to use these features.

The **Tools - Administrator Console** dialog provides a user interface for DBMS administrators to configure and manage Manifold geospatial data storage within enterprise DBMS data stores. The **Administrator Console** includes the following capabilities:

- Designate tables containing geometry columns to be treated as drawings by Manifold clients.
- Specify a generic spatial index to be used with tables containing geometry columns.
- Designation of user-friendly, **component** names for Manifold components stored within databases. These user-friendly component names can then appear within Database Console in all Manifold editions capable of connecting to that data source. Friendly names make it a lot easier for users to find their data within large databases when linking drawings or other components.
- Automatic creation and maintenance of an internal metadata table, called **MFD_META** by default, within the data source that is used to store housekeeping and metadata information on database objects for use by Manifold System.
- Displaying the number of objects in drawings and the dimensions and number of channels in images.
- Displaying the projections of drawings and images.
- Editing the coordinate system of a database object by double clicking the relevant cell in the **Projection** column.
- Enabling and disabling storing formatting of a database drawing object in the data source by double clicking the relevant cell in the **Format** column. When enabled, formatting is stored in the metadata table in XML format.
- Viewing and editing the location precision of a drawing database object via the **Precision** column.
- Viewing the number of records in tables and views via the **Statistics** column.
- Viewing triggers bound to a database object via the **Triggers** toolbar button. This capability is enabled only for Oracle native data sources.
- Editing the default link options of a database table object containing geometry data in one of the supported binary column geometry formats so it behaves like a drawing. This allows easy views of such database objects as drawings in subsequent Manifold sessions.
• Editing the default link options (geometry column and type, version column, server version increment option, formatting storage) and other properties (friendly name, coordinate system, precision) of a database object via the Properties toolbar command. This allows rapid and simplified linking in subsequent Manifold sessions.

Note: image capabilities apply if the data source in use supports images. Currently, only Oracle data sources with GeoRaster capability support linked image storage.

**Administrator Console Layout**

When connected to a data source the Administrator Console shows database objects in the data source in a contents pane. The lower pane is a command pane in which commands may be written using the command language of the data source, normally SQL.

Highlighting an object by clicking on it makes it the context object (that is, puts the focus on that object) so that toolbar buttons such as the Properties or Trigger button can operate on it. The status bar will also report information on the context object.

**Controls**

**Data Source** Choose the name of a data source, or press the browse button to launch the Connect To dialog to specify a data source. ADO.NET, ODBC, OLE DB and file-based data sources may also be used. The Server box will show the last used name or connection string (Manifold will not actually connect to the last used name or connection string until the Refresh button is pressed). Any PASSWORD and PWD parameters used in a connection string will be masked in the last used name or connection string to protect security.
(contents pane) Displays the contents of the data source.

**Refresh** - Update the contents pane.

**Properties** - Launch the Properties dialog for the highlighted database object. Allows specification of the friendly name, precision, version column, formatting and server version incrementing options. Also used to configure tables for treatment as drawings with specification of geometry columns and geometry data type.

**Triggers** - Launch the Triggers dialog for the highlighted database object. View and edit triggers bound to the database object (Oracle only). Shows the trigger, type of trigger and event for each trigger as well as the procedure text.

**Run** - Press to execute the command line text in the command pane.

**Global Filter** - Launches a dialog enabling filtering the names of database objects using regular expressions. Changes to the global filter are saved between different sessions of Manifold. By default, the global filter includes several masks suppressing display of system tables commonly found in Oracle databases. See the Tools - Database Console topic for use of the Global Filter button.

**Columns** - Toggle display of desired columns on or off in the contents pane. Manifold will remember the last used columns between sessions. Data is fetched for columns from the data source on demand.

Columns include:

- **Component** - Show the "friendly" name, that is, the Manifold component name.
- **Format** - Enable storage of formatting for drawings. Double-click into the Format cell of a database object to enable or disable formatting.
- **Precision** - Show location precision used in drawings.
- **Projection** - Projection used by this database object. Double-click into the Projection cell of a database object to launch the database object Projection dialog.
- **Spatial Index** - Reports if a generic spatial index is present for this object. Double-click into the Spatial Index cell of a database object to launch a dialog that enables creating and editing the spatial index. The bounding box of the area covered by the index is editable.
- **Statistics** - Useful information, such as the number of objects in drawings or the number of records in tables.
- **Triggers** - The number of database triggers, if any, for this object. Double-click into the Triggers cell of a database object to launch the database object Triggers dialog.

**Filter** Filter by character sequence - Show only those database objects in the contents pane the name of which contain the given sequence of characters. This is particularly helpful when working with data sources with lots of objects, such as SQL Server or Oracle data sources. See the Tools - Database Console topic for use of the Filter box.

(command pane) A text pane in which command lines, such as SQL, can be entered to be executed by the data source.

(status bar) Information about the highlighted object will be provided
at the bottom of the dialog.

Spatial Index Dialog Controls

The spatial index dialog appears when double-clicking into the Spatial Index cell for a database object that Manifold has been instructed to treat as a drawing.

Object
The database object to index. This will be a table name followed by a dot followed by the geometry column to be indexed. A typical name in SQL Server Express, for example, might be `dbo.Mexico Table.GeomI` if we exported a table using the `Geom (I)` intrinsic field to provide a geometry column.

Use spatial index
Check to create a spatial index.

X and Y boxes
Four boxes for the X and Y extents to be covered by the spatial index, initially blank until the Suggest button is pressed. The outer two boxes (not editable) show the extents of the data set. The inner two boxes show the extent of the spatial index to be constructed. This is normally the full extent of the data set, although in special cases users may wish to create a spatial index that covers less than the entire data set.

Level
Degree of detail in the spatial index, providing a balance between granularity and performance. Higher values produce more granular indices, which require more space but are potentially more efficient. For best efficiency, choose an index level proportional to the number of objects expected to be in the drawing. The value suggested by the Suggest button is a reasonable default.

Suggest
Press this button to command Manifold to analyze the data set to determine the extents of the data and a recommended

Designating a Friendly Name

To enter a friendly name for a database object, click on the object to highlight it and then double-click into the Component cell for that object or press the F2 key. Friendly names may include spaces and can be any component name legal within a Manifold project.

Using Friendly Names within the Database Console

To use friendly names within Database Console, connect to a data source that has a metadata table and friendly names designated with Administrator Console, and turn on component view using the Component View toolbar button. If the data source does not contain a metadata table set up with Administrator Console, the component view button will be disabled.

When in component view, the Database Console dialog will only show components that have been assigned friendly names. The Filter box will work with friendly names as well.

The MFD_META Table

DBMS administrators may be interested in additional information about the MFD_META metadata table that is created and used by the Administrator Console. Friendly names are stored in the metadata table and are available to all Manifold clients connecting to the data source.

The metadata table is named `MFD_META` by default and contains three fixed-length or variable-length text columns named OBJ, PROP and VAL. The OBJ column stores names of database objects, the PROP column stores property names, and the VAL object stores property values. If there is both a system table named `MFD_META` and a user table named the same (as might be the case with Oracle data sources), the system table is given preference.
Supported properties are:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component</td>
<td>Friendly name. Can include spaces, punctuation and other characters allowed in a Manifold component name.</td>
</tr>
<tr>
<td>CoordinateSystem</td>
<td>The coordinate system of a table behaving as a drawing, in Manifold XML format.</td>
</tr>
<tr>
<td>Epsilon</td>
<td>The location precision parameter of a table behaving as a drawing, in native drawing units.</td>
</tr>
<tr>
<td>Format</td>
<td>True or False, depending on whether or not a drawing should store formatting on the data source.</td>
</tr>
<tr>
<td>FormatAreaBack</td>
<td>Area background color format for a drawing, in Manifold XML format.</td>
</tr>
<tr>
<td>FormatAreaBorderBack</td>
<td>Area border background color format for a drawing, in Manifold XML format.</td>
</tr>
<tr>
<td>FormatAreaBorderFore</td>
<td>Area border foreground color format for a drawing, in Manifold XML format.</td>
</tr>
<tr>
<td>FormatAreaBorderSize</td>
<td>Area border size format for a drawing, in Manifold XML format.</td>
</tr>
<tr>
<td>FormatAreaBorderStyle</td>
<td>Area border style format for a drawing, in Manifold XML format.</td>
</tr>
<tr>
<td>FormatAreaFore</td>
<td>Area foreground color format for a drawing, in Manifold XML format.</td>
</tr>
<tr>
<td>FormatAreaSize</td>
<td>Area size format for a drawing, in Manifold XML format.</td>
</tr>
<tr>
<td>FormatAreaStyle</td>
<td>Area style format for a drawing, in Manifold XML format.</td>
</tr>
<tr>
<td>FormatLineBack</td>
<td>Line background color format for a drawing, in Manifold XML format.</td>
</tr>
<tr>
<td>FormatLineFore</td>
<td>Line foreground color format for a drawing, in Manifold XML format.</td>
</tr>
<tr>
<td>FormatLineSize</td>
<td>Line size format for a drawing, in Manifold XML format.</td>
</tr>
<tr>
<td>FormatLineStyle</td>
<td>Line style format for a drawing, in Manifold XML format.</td>
</tr>
<tr>
<td>FormatPointBack</td>
<td>Point background color format for a drawing, in Manifold XML format.</td>
</tr>
<tr>
<td>FormatPointFore</td>
<td>Point foreground color format for a drawing, in Manifold XML format.</td>
</tr>
<tr>
<td>FormatPointRotation</td>
<td>Point rotation format for a drawing, in Manifold XML format.</td>
</tr>
<tr>
<td>FormatPointSize</td>
<td>Point size format for a drawing, in Manifold XML format.</td>
</tr>
<tr>
<td>FormatPointStyle</td>
<td>Point style format for a drawing, in Manifold XML format.</td>
</tr>
<tr>
<td>GeometryColumn</td>
<td>Name of a column to use for geometry data. If present, makes the table behave as a drawing.</td>
</tr>
<tr>
<td>GeometryColumnType</td>
<td>Data type of the column used to store geometry data. Can be Manifold for Geom, SDE for GeomSDE, SHP for GeomSHP, or WKB for GeomWKB. If absent or invalid, the data type is assumed to be Geom.</td>
</tr>
<tr>
<td>VersionColumn</td>
<td>Name of a column to use for version data, for drawings.</td>
</tr>
<tr>
<td>VersionColumnAuto</td>
<td>True or False depending on whether or not Manifold should rely on the server to increment version data after making changes to the metric of drawing objects.</td>
</tr>
</tbody>
</table>
Tech Tip

Almost always after specifying that a table containing geometry be interpreted as a drawing we will click into the Spatial Index column for that table object in Administrator Console to specify a generic spatial index for that table. Specifying a spatial index will enable Manifold clients importing or linking that table as a drawing to work with only the area of interest desired. This is potentially a huge performance enhancement when working with very large drawings.

Keep in mind that the choice of connection technology will influence how Manifold interacts with the DBMS. For example, ADO .NET connections typically are read-only and will not allow either Administrator Console or Database Console to make changes, such as adding a spatial index, to the database. In another example, connecting to a spatial DBMS using the native connection technology (such as using OCI to connect to Oracle) tells Manifold we want to use the DBMS’s native spatial technology, while using ODBC or OLE DB tells Manifold to connect in a generic way. See the Spatial DBMS Facilities topic for additional information.

Database Object Projection

This topic describes a feature that is provided only within Manifold Database Administrator Edition and is not available in other Manifold System editions. If you have purchased and installed Database Administrator Edition the features described in this topic will be available to you. If you have installed some other Manifold System edition you will not be able to use these features.

Launch the database object Projection dialog within Administrator Console by double-clicking into the Projection column cell for a database object or by highlighting the object, clicking the Properties toolbar button and then clicking the [...] browse button for Projection in the Properties dialog.

The database object Projection dialog has two uses:

- For components exported to Oracle databases from Manifold System it allows changing the Oracle coordinate system in use. The usual course of events is that when a component is exported from Manifold into Oracle the coordinate system assigned is matched and, if necessary, altered in the export dialog. The database object Projection dialog in the Administrator Console allows changing this projection.

- The second use of the database object Projection dialog is to assign a projection to a drawing stored in a non-Oracle database in a table using a geometry format such as WKB that does not save coordinate system information. In that case, the Assign Projection dialog is raised and used as it would be to assign the projection to a drawing in Manifold that was imported from a GIS format that does not store projection information.

The illustration above shows the database object Projection dialog for a drawing stored in Oracle. The controls specified below are for that Oracle form of the database object Projection dialog.

**Controls**

- **Original**
  - Original coordinate system used within Manifold.

- **Map to**
  - A list of Oracle coordinate systems with the SRID and Name for each. The coordinate system in use is highlighted.

  (description pane) Detailed description of the Oracle coordinate system.
Comments, for example, noting that a given Oracle coordinate system is exactly the same as the original Manifold coordinate system.

**Auto**  Automatically choose the Oracle coordinate system that is the best match to the original Manifold coordinate system.

Database Object Properties

This topic describes a feature that is provided only within Manifold Database Administrator Edition and is not available in other Manifold System editions. If you have purchased and installed Database Administrator Edition the features described in this topic will be available to you. If you have installed some other Manifold System edition you will not be able to use these features.

Highlight a database object and click the **Properties** toolbar button in the Administrator Console dialog to launch the **Properties** dialog for that object.

The **Properties** dialog has the following uses:

- For drawings, the **Properties** dialog allows setting default options for subsequent import or linking back into Manifold projects. Settings made via the **Properties** dialog will be automatically incorporated when users later employ **Database Console** to import or link the component into their projects. This eliminates the need for ordinary users to know how to handle various options.

- For tables or queries which incorporate geometry data in the form of binary columns, the **Properties** dialog allows use of such database objects as drawings within Manifold. The Manifold database administrator can use the **Properties** dialog to designate such tables as drawings and to set forth which columns in that table should be treated as containing geometry and what type of geometry format is used.

- For images, the **Properties** dialog allows setting basic properties such as the coordinate system and the friendly name. Manifold works with images via Oracle GeoRaster technology, which requires the use of Enterprise Edition and an Oracle product that supports GeoRasters, such as Oracle Spatial (Oracle Express does not support GeoRasters). See the Oracle Spatial Facilities topic for details.

### Controls

- **Object** Context database object (item that was highlighted when the **Properties** button was clicked).

- **Name** Manifold component name, also referred to as the friendly name.

- **Treat as drawing** Checked by default (and disabled) for all Manifold drawings uploaded by Manifold into the database. Should be checked for tables that contain geometry data that are to be treated by Manifold as drawings.
Projection  Projection used by the component. Click the [...] browse button to specify the database projection to be used for this object via the database object Projection dialog.

Precision  Location precision used for this drawing.

Geometry  Name of the column used to store geometry. Filled in by default for drawings uploaded by Manifold.

Type  Type of geometry storage used in the geometry column, one of the geometry storage types usable by Manifold (see the Geometry in Tables topic). The Manifold type, Geometry, is automatically mapped in the case of Oracle into SDO_GEOMETRY so that when Geometry appears in this box for Oracle tables we know that the actual storage is SDO_GEOMETRY.

Version  The column to use for versioned editing in concurrent multi-user editing scenarios. See the Multi-User Editing of Linked Drawings topic. The table must contain a primary key to allow a version column to be designated.

Rely on server to increment version automatically  Use a trigger in the server to automatically increment the version column to support versioned editing. The default setting for Oracle.

Store formatting on server  Enable storage of drawing formatting within the database. Uses the metadata table created and managed by Administrator Console to store formatting.

Example

This example assumes we have uploaded a table that contains geometry data in OGC WKB format. We will use the database object Properties dialog to configure this table for use as a drawing within Manifold.

This is something of an artificial example using manual creation of geometry and manual upload and configuration via the Properties dialog. Exporting a drawing to SQL Server using default settings will automatically configure the drawing in the database for subsequent importing or linking into Manifold.

However, it could be the case that if we are using non-Manifold sources of geometry data (such as some other application that writes WKB data) we will need to configure it for use as a drawing within Manifold. This example shows how to do that.

Step 1: Arrange Example Data

Before we can get to the main part of the example, showing how to work with geometry data in tables within a database, let's create some example data and put it into a database. We will deliberately use a highly manual way of creating geometry data using an "open" geometry type, WKB, to simulate a situation where some third party application may have written geometry data to our SQL Server database.

```
<table>
<thead>
<tr>
<th>Name</th>
<th>geom geom</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minnesota</td>
<td>&lt;geom wkb, polygon&gt;</td>
<td>0</td>
</tr>
<tr>
<td>Washington</td>
<td>&lt;geom wkb, multipolygon&gt;</td>
<td>0</td>
</tr>
<tr>
<td>Idaho</td>
<td>&lt;geom wkb, polygon&gt;</td>
<td>0</td>
</tr>
<tr>
<td>Montana</td>
<td>&lt;geom wkb, polygon&gt;</td>
<td>0</td>
</tr>
<tr>
<td>North Dakota</td>
<td>&lt;geom wkb, polygon&gt;</td>
<td>0</td>
</tr>
<tr>
<td>Michigan</td>
<td>&lt;geom wkb, multipolygon&gt;</td>
<td>0</td>
</tr>
<tr>
<td>Maine</td>
<td>&lt;geom wkb, multipolygon&gt;</td>
<td>0</td>
</tr>
<tr>
<td>Wisconsin</td>
<td>&lt;geom wkb, multipolygon&gt;</td>
<td>0</td>
</tr>
<tr>
<td>Oregon</td>
<td>&lt;geom wkb, polygon&gt;</td>
<td>0</td>
</tr>
<tr>
<td>South Dakota</td>
<td>&lt;geom wkb, polygon&gt;</td>
<td>0</td>
</tr>
</tbody>
</table>
```
Consider a table that contains geometry information in OGC WKB form within a column called `wkbgeom`. The table has had a `Version` column added to it suitable for use with versioned editing if this table will at some point be treated as a drawing. The `Version` column is simply a long integer type.

**Note:** For the sake of this example, the above table was created within Manifold beginning with the US_Main sample drawing as follows: First, the drawing was imported into Manifold. Next, the drawing’s table was opened and a new field called `wkbgeom` was added to the table as a Geometry (WKB) type. The transform toolbar was then used to copy the contents of the Geom (I) intrinsic field to the `wkbgeom` field, with Manifold automatically converting the `geom` type into the WKB geometry type on the fly. Finally, we deleted all columns except those seen above and we added a `Version` column.

The result is a table like that created by some other software package we might encounter in a database. For the sake of this example, we export the table into a SQL Server 2005 Express Edition database using an OLE DB connection in the Data Source dialog.

**Step 2: Launch Administrator Console Properties Dialog**

We connect to the SQL Server database with Administrator Console and see the database object representing the table uploaded in the previous step.

**Administrator Console** shows the database object as a table. We can click on it to highlight it and then press the Properties toolbar button to launch the Properties dialog.

**Note:** If we had uploaded the table into an Oracle database, Manifold would have converted the geometry column automatically into native Oracle SDO_GEOMETRY. Connecting to the Oracle database with Administrator Console would then automatically have shown the table as a drawing. We deliberately used SQL Server in this example so that the automatic conversion would not be done, therefore allowing us to show in this example how to use Administrator Console to specify treatment of a table as a drawing.
The **Properties** dialog shows the table with no other information initially. We will first give it a component name and check the box for it to be treated as a drawing.

We provide a friendly, component name and check the **Treat as drawing** box. When we check the box Manifold will enable the other controls used with drawings. We will begin by clicking the [...] browse button to specify the **Projection** to be used.
Manifold launches the Assign Projection dialog using default Orthographic projection. If this data is not intended to represent data in Orthographic projection, now is the time for us to specify the coordinate system that it uses.
Because we created this table for this example from the sample US Main drawing, we know that the data uses Latitude / Longitude and WGS84 datum and we can set the Assign Projection dialog accordingly. If we did not know that, there is nothing about the OGC WKB format for geometry that would have told us that. Unlike sensible geometry types for databases, such as Oracle spatial types or Manifold’s Geom type, the WKB format created by the Open GIS Consortium is too stupid to represent GIS notions such as the coordinate system to be used for data. [Chalk up another example for why the phrase “design by committee” is used as pejorative.]

Press OK to close the Assign Projection dialog and assign the new projection.
We can see that now the Projection is reported as Latitude / Longitude. We note that the Precision value is still empty, so we'll have to fill that in.

The Geometry column has already been correctly pre-loaded with the wkbgeom column name. If there were more than one binary data column in the table Manifold would not know that the binary data wkbgeom column is the right one, but since it is the only binary column type in the table and we've already told Manifold this table is to be treated as a drawing, Manifold knows it is a safe bet that the only binary column in the table is the one to guess we intend to use for the Geometry column. However, we have to tell Manifold what Type of geometry data is in that column. Manifold has loaded the box with Geometry as the type, that choice being simply the first choice in alphabetical order.

We specify the Precision value (another magic number we know from our experience with the US Main drawing that otherwise would be impossible to know).

For the Type column we choose Geometry (WKB), the data type used for OGC WKB data.
Finally, we choose Version for the version column and check the Store formatting on server box and press OK.

These last two settings are Manifold-specific choices, since only Manifold can use the Version column for versioned, concurrent multi-user editing and only Manifold will be using any formatting used for this drawing from Manifold clients. For the sake of completeness we show these choices.

As a practical matter, it is slightly goofy to use WKB as a storage format for drawings that will be used exclusively with Manifold. A much better choice is Manifold Geometry type for storage within SQL Server or DB2. Better still, use SDO_GEOMETRY within Oracle (effectively the same thing, since with Oracle Manifold Geometry is automatically converted to and from SDO_GEOMETRY on the fly).

Using Manifold Geometry within SQL Server is great, but does not allow interoperability with old-fashioned GIS applications. If fast and modern interoperability is the goal, using Oracle SDO_GEOMETRY delivers it. Hundreds of GIS applications can interoperate with Oracle SDO_GEOMETRY, so if one wants to use an "open" format that is sensibly designed for geometry storage SDO_GEOMETRY as a practical matter is just the ticket.

WKB is used only when we must retain the ability to interoperate with old-fashioned GIS software using non-Oracle DBMS servers. But, at least it's there for those users who get forced into such things, hence this example.
Back in Administrator Console the display will be immediately updated with the new information on the database object. If we press Refresh we will also see, as in the illustration above, that a new table has appeared in the database, the MFD_META table maintained by Administrator Console in support of Manifold features such as component names (friendly names) and formatting.

If some other Manifold user used Database Console to connect to that SQL Server database he or she would see a drawing listed under the friendly, component name we assigned using Administrator Console.
Users can simply click on the drawing and press **Link** to immediately link the drawing into the project.

The drawing is immediately linked without any need for intermediate dialogs, since **Administrator Console** was already used to specify desired import and link options. For example, the **Version** column is automatically specified to enable versioned editing with no need for users to remember to specify a version column.

Double-clicking the drawing in the project pane opens it and shows that it does capture the **US Main** example drawing within the **WKB** geometry stored in the SQL Server table.
We can format the drawing as seen above, assigning a thematic format to area background color using the **Area** (I) intrinsic field, so states are colored in natural breaks using their sizes. Since storage of formatting has been automatically turned on for us by the settings made in **Administrator Console**, whatever formatting we apply will persist on the server and will be available the next time we link the drawing into another Manifold project.

**Tech Tip**

Almost always after specifying that a table containing geometry be interpreted as a drawing we will click into the **Spatial Index** column for that table object in **Administrator Console** to specify a generic spatial index for that table. Specifying a spatial index will enable Manifold clients importing or linking that table as a drawing to work with only the area of interest desired. This is potentially a huge performance enhancement when working with very large drawings.

Database Object Triggers

This topic describes a feature that is provided only within Manifold Database Administrator Edition and is not available in other Manifold System editions. If you have purchased and installed Database Administrator Edition the features described in this topic will be available to you. If you have installed some other Manifold System edition you will not be able to use these features.

Triggers are procedures that run implicitly before or after certain actions, as specified by the database administrator. At present, Manifold shows triggers only in native Oracle data sources.

The languages that may be used to write triggers vary from one database to another. In Oracle we can write actions in PL/SQL, Java or C while in SQL Server, we can write actions in T-SQL or .NET languages, such as VB .NET and C#.

The actions to which triggers can be bound also vary between databases. Most databases can schedule triggers to run before or after inserting, updating or deleting records in a particular table. Many databases support binding triggers to numerous other actions. Some actions can be initiated by users, and some by the database itself.

In some cases Manifold provides options to automatically create triggers to support system functionality. For example, when exporting a drawing to a native Oracle data source Manifold provides an option to automatically create a trigger to populate ID column values for newly inserted records, and another trigger to update version column values in changed records. We would normally choose to create such triggers but sometimes this will be unnecessary or undesired due to database design policies or for other reasons.

![Triggers dialog]

Highlighting a database object in Administrator Console and pressing the Triggers toolbar button launches the Triggers dialog to show any triggers associated with that object. Double-clicking into the Triggers column cell for that database object will also launch the Triggers dialog.

Controls

- (object name) Context database object (item that was highlighted when the Properties button was clicked).
- (triggers pane) A list of triggers for this object, showing for each trigger the name, type of trigger and type of event.
- (procedure pane) The procedure for the trigger highlighted in the triggers pane.
The *Triggers* dialog will show all triggers, not just those added by Manifold. It is therefore a handy tool to examine database objects to help troubleshoot complex databases that may include numerous objects unrelated to Manifold operations or to identify unwanted triggers added in error to Manifold objects.

**Example**

The UPDATE trigger written by Manifold to enable automatic server side incrementing of the *Version* column to support versioned editing is a classic example of a trigger.

To see such an example, connect to an Oracle database that contains a drawing for which the *Rely on server to increment version automatically* option has been enabled, click on the drawing to highlight it in *Administrator Console* and press the *Triggers* toolbar button.

Click on the UPDATE trigger in the *Triggers* dialog to see the procedure for that trigger in the procedures pane.

Spatial DBMS Facilities

Manifold includes extensive features to take advantage of spatial DBMS capabilities, even with those DBMS products that do not provide native spatial DBMS capability. Before continuing with this topic, please see the Spatial DBMS topic for a general introduction to spatial DBMS and Manifold.

Manifold Enterprise Edition or above is required to connect using native connections to spatial DBMS such as Oracle Spatial, DB2 with IBM Spatial Extender, SQL Server 2008 spatial and PostgreSQL / PostGIS.

Storing Drawings within Spatial DBMS

Manifold features integrated read / write / edit, multiuser connections to a variety of spatial DBMS packages. In general, operation is fully automatic: when a Manifold drawing is uploaded to a spatial DBMS the Manifold geometry will automatically be converted into the native DBMS geometry type. When a drawing is linked or imported from a spatial DBMS source the native DBMS geometry will be automatically cast into Manifold geometry.

Manifold provides two ways of storing drawings within spatial DBMS:

- **Native storage within a spatial DBMS** - Examples are Oracle Spatial, IBM DB2, Microsoft SQL Server 2008 or PostgreSQL using the native geometry type specified by the DBMS. Connecting to one of these spatial DBMS packages using the "native" connection, such as OCI for Oracle, tells Manifold to automatically convert local Manifold geometry for drawings into whatever the target spatial DBMS users as its own native geometry type.

- **Non-native storage within almost any DBMS** - Manifold can confer spatial DBMS capability to almost any DBMS. When using Manifold-managed spatial storage, we have the choice of what geometry type we would like to use. Examples are storing drawings as tables within, say, MySQL or SQL Server using any of the binary geometry types supported by Manifold, such as GeomWKB (OGC WKB), GeomSHP (legacy ESRI geodatabases), or GEOMETRY (Manifold's own high performance geometry type, often abbreviated GEOM). Normally the choice will be made between Manifold GEOM type or OGC WKB type. In addition, Manifold can establish a generic spatial index. The spatial index is used together with the binary data to allow "ordinary" DBMS packages to function as a spatial DBMS. A special case of Manifold-managed storage is the use of the Manifold Spatial Extender for SQL Server 2005 to provide especially fast spatial DBMS capability within SQL Server 2005. See the Example: Storing a Drawing in Manifold Spatial DBMS topic.

It is quite possible to use any of the above storage methods within the same DBMS. For example, Oracle provides Locator spatial capability so drawings can be stored in Oracle using Oracle's native SDO_GEOMETRY type as with a typical spatial DBMS. But Oracle also provides a full roster of other DBMS types, including generic binary storage, which may be used for non-native geometry types. If desired, we can store non-native geometry within Oracle tables, establish generic indices and so on. In fact, within the same Oracle Spatial DBMS Manifold could have three different drawings stored as three different tables with each table using a different geometry type.

Storing Images and Surfaces within Spatial DBMS

Manifold provides two ways of storing images and surfaces within a DBMS:

- **Oracle GeoRaster** - Connecting via OCI (Oracle's native Oracle Call Interface) to an Oracle database that has GeoRaster capability (Oracle Spatial or Oracle Enterprise) allows us to store images within Oracle's native GeoRaster data type. See the Example: Storing an Image in Oracle topic.

- **Generic image storage** - Connecting via ODBC or OLE DB to almost any DBMS that allows binary storage allows us to store images and surfaces (which are stored as images with an additional Height channel). Images are stored as tiles, with the export process allowing choice of a tile size. Exporting an image to such a data source creates a table with a record for each image tile. Image tiles are stored in compressed or uncompressed BGR(A) format. Importing or linking images from such a data source automatically reassembles tiles. Surfaces cannot be linked, but can be imported by importing the Height channel of the image that is stored for them into the database. See the Example: Storing an Image in Manifold Spatial DBMS and Example: Storing a Surface in Manifold Spatial DBMS topics.

Manifold uses Database Console to connect to a database storing images to import or link to a stored image. Database console will recognize tables containing image tiles and will display them as images, allowing us to
import or link to the image by using the database console's Import or Link buttons. We can also import individual channels of such images as surfaces.

**Specifying the Spatial DBMS Technology to Use**

If Manifold can work with spatial DBMS using either a vendor's native spatial DBMS technology or spatial DBMS technology provided by Manifold, how do we specify which technology we would like to use for any particular drawing?

- **Choice of Type in Export Drawing Dialog** - When exporting a drawing to a database the Export dialogs give us a Type box which allows us to specify either Manifold, for Manifold-managed geometry types or, if a native connection technology was used to connect to a spatial DBMS, the name of that spatial DBMS vendor. Note that we must use the native spatial DBMS connection (see below) in the Data Source dialog to enable use of native spatial DBMS capabilities.

- **Automatic Choice when Importing or Linking** - Manifold dialogs for importing or linking will automatically use whatever technology is used for storage of that component. When Database Console connects to a data source Manifold will examine the source and determine what technology is in use and use that technology when importing or linking any given component.

For example, if we connect to an Oracle server when exporting a drawing we will see two choices available in the Type box: Manifold, and Oracle. Choosing Oracle will export the drawing into Oracle's native spatial system using SDO_GEOMETRY. Choosing Manifold will export the drawing using whatever non-native geometry type we specify in the dialog together with creation of a Manifold-established spatial index.

When importing or linking from a database if we want to use a spatial DBMS's native spatial facilities we must connect using that DBMS's native connection technology. Once connected, Manifold will automatically recognize whether the data in use is the vendor's native spatial geometry, Manifold-managed non-native spatial geometry or ESRI SDE geodatabase or Personal geodatabase geometry (see below for information on ESRI geodatabases).

**Data Source Connections for Spatial DBMS**

In addition to the usual roster of ADO.NET, OLE DB, and ODBC connections Manifold Enterprise Edition and higher editions provide specialized native DBMS connection choices that are used when adding a new data source using a spatial DBMS in the Data Source dialog:

<table>
<thead>
<tr>
<th>ADI.NET Data Sources</th>
<th>OLE DB Data Sources</th>
<th>ODBC Data Sources</th>
<th>PostgreSQL Data Sources</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB2 Data Sources</td>
<td>Oracle Data Sources</td>
<td>SQL Server Data Sources</td>
<td></td>
</tr>
</tbody>
</table>

- **DB2 Data Sources** - Connect to IBM DB2 equipped with the DB2 Spatial Extender using IBM's native spatial connection technology.

- **Oracle Data Sources** - Connect to Oracle using OCI, the Oracle Call Interface to utilize Locator or Oracle Spatial facilities.

- **PostgreSQL Data Sources** - Connect to PostgreSQL equipped with the PostGIS spatial extender using native PostgreSQL connection technology. Connections made using this data source will have any password required masked so that later usage will not inadvertently expose the password.

- **SQL Server Data Sources** - Connect to Microsoft SQL Server 2008 spatial DBMS facilities using native SQL Server 2008 spatial connection technology.
Users sometimes ask if there is a special connection when using SQL Server 2005 as a spatial DBMS with the Manifold Spatial Extender for SQL Server installed. There is no need for a special connection because Manifold when connecting to SQL Server using any OLE DB connection will recognize and automatically use spatial indices managed by the spatial extender when the Manifold spatial extender has been installed.

**When Enterprise Edition is Required**

Manifold Enterprise Edition or above is required to connect using native connections to spatial DBMS such as Oracle Spatial, DB2 with IBM Spatial Extender, SQL Server 2008 spatial and PostgreSQL. Therefore, any usage of native spatial capabilities within these spatial DBMS products requires Enterprise Edition or above.

Manifold Enterprise Edition or above is required to create a spatial index when using Manifold to confer generic spatial DBMS capability upon almost any DBMS; however, once Enterprise Edition is used to create the spatial index any Manifold edition may be used to work with that data and that generic spatial index.

For example, we could use an Enterprise Edition license to load a SQL Server 2005 database with drawings supported with spatial indices, images and surfaces. We could then have many of our colleagues work with those drawings (including full read/write/edit capabilities), images or surfaces using Personal Edition licenses. However, if any of our colleagues wanted to upload a new drawing into that SQL Server database they would have to use an Enterprise Edition license to upload the drawing with an associated spatial index.

As a practical matter, large organizations that are working seriously with spatial DBMS using a natively spatial DBMS like Oracle Spatial or SQL Server 2008 will deploy Manifold using Enterprise licenses. Because of the very low cost of Enterprise Edition even those organizations that will use non-native spatial DBMS will tend to deploy Manifold using exclusively Enterprise Edition licenses so that all users can upload new drawings at any time.

In some specialized settings it can be useful to employ Personal or Professional licenses to connect to spatial DBMS to work with drawings previously uploaded using Enterprise Edition. Examples include small organizations on a budget, custom applications that utilize a Professional Runtime license, or organizations where there are many users with very undemanding, mainly "view only" interactions who will never be creating new drawings.

**Supported Spatial DBMS**

Current spatial DBMS products with spatial types understood by Manifold include:

- **IBM DB2 with Spatial Extender** - Spatial DBMS functionality with DB2 depends upon installation of the IBM Spatial Extender for DB2.
- **Microsoft SQL Server 2005** - Implemented using the Manifold Spatial Extender for SQL Server or through use of Manifold-managed generic spatial DBMS capability. See the SQL Server Spatial DBMS Facilities topic.
- **Microsoft SQL Server 2008** - Microsoft has engineered spatial DBMS functionality into SQL Server 2008. Manifold supports SQL Server 2008 spatial extensions today and has since the very first SQL Server 2008 spatial pre-release in 2007. See the SQL Server Spatial DBMS Facilities topic.
- **Oracle Spatial and Oracle Locator** - All Oracle products now have Locator capability to allow spatial DBMS capabilities with vector drawings. Oracle Spatial is required to store images and surfaces using Oracle's GeoRaster type. See the Oracle Spatial Facilities topic for additional information.
- **PostgreSQL** - An open source DBMS that is extended into a spatial DBMS via the PostGIS package.
- **ESRI SDE and Personal Geodatabases** - Not really a separate spatial DBMS but rather a collection of proprietary ESRI types, metadata tables and facilities imposed upon one of the DBMSs supported by ESRI. Since many ESRI people think of these as spatial DBMS they are enumerated here because Manifold can interact with them as well. See the ESRI Geodatabases topic.

In addition to the usual roster of ADO .NET, OLE DB, and ODBC connections Manifold Enterprise Edition and higher editions provide specialized native DBMS connection choices that are used when adding a new data source using a spatial DBMS in the Data Source dialog. See the Data Source dialog topic for a current list.

For specific discussion of different ways to use SQL Server in spatial DBMS, see the SQL Server Spatial DBMS Facilities topic.

**Notes on Specific Spatial DBMS Products.**
Oracle and SQL Server have dedicated topics discussing operations with those DBMS products. See the Oracle Spatial Facilities and the SQL Server Spatial DBMS Facilities topics.

**IBM DB2**

When IBM's DB2 Spatial Extender has been install we can use DB2 as a spatial DBMS, taking advantage of native DB2 geometry. The IBM Spatial Extender for DB2 is a free download for DB2 Express-C and other DB2 editions.

Manifold usage of DB2 spatial DBMS data sources uses Database Console as the primary interface and includes:

- Connecting to an DB2 data source via the native DB2 interface. The native DB2 interface is faster and more robust than accessing DB2 through intermediate database layers such as ODBC or OLE DB. Manifold will remember the last DB2 data source to which a successful connection has been made. Omitting a login name when connecting to a native DB2 data source uses integrated security.
- Importing, linking and exporting tables.
- Listing the drawings in an DB2 data source in Database Console.
- Importing drawings.
- Linking drawings in read-write mode.
- Exporting drawings.

When importing, linking or exporting drawings, reading data will automatically and transparently translate DB2 geometry into Manifold Geom values. Writing data will automatically and transparently translate Manifold Geom values into DB2 Geometry.

When linking a drawing or table from a native DB2 data source Manifold will examine the DB2 table privileges. If the detected table privileges do not allow writing the resulting component within Manifold will be read-only.

To work with DB2 data sources we must have all DB2 client DLLs (for example, DB2CLI.DLL plus any DLLs it depends on) to be installed in a folder referenced in the user's or system's PATH variable. The easiest way to be sure this is done is include the folder containing all DB2 client DLLs in the system PATH variable.

**PostgreSQL / PostGIS**

PostgreSQL (pronounced "post-gres-que-ell" in English) is an open source DBMS that has been extended into spatial capabilities via the PostGIS set of open source extensions.

Manifold usage of PostgreSQL data sources uses Database Console as the primary interface and includes:

- Connecting to a PostgreSQL data source via the native PostgreSQL interface. Manifold will remember the last PostgreSQL data source to which a successful connection has been made.
- Importing, linking and exporting tables.
- Listing the drawings in a PostgreSQL data source in Database Console.
- Importing drawings.
- Linking drawings in read-write mode.
- Exporting drawings. When exporting a drawing to a PostgreSQL data source there is an option to create a spatial index (on by default), and an option to create a sequence and an update trigger (on by default), similar to the options provided for export to Oracle. See the Example: Storing a Drawing in Oracle and Export Drawing - Oracle topics.

To work with PostgreSQL data sources we must have all PostgreSQL client DLLs (for example, LIBPQ.DLL plus any DLLs it depends on) to be installed in a folder referenced in the user's or system's PATH variable. The easiest way to be sure this is done is include the folder containing all PostgreSQL client DLLs in the system PATH variable.
When importing, linking or exporting drawings, reading data will automatically and transparently translate PostgreSQL geometry into Manifold Geom values. Writing data will automatically and transparently translate Manifold Geom values into PostgreSQL Geometry.

Exchanging geometry data with PostgreSQL tolerates data with Z and M values, although Z and M values are not used by Manifold. Reading geometry data with Z and M values throws these values away. Writing geometry data with Z and M values inserts zeros.

**ESRI Geodatabases**

Not really a spatial DBMS in the sense of the above DBMS products, ESRI SDE and Personal geodatabases are discussed in the ESRI Geodatabases topic.

**Deleting Drawings stored within Spatial DBMS**

Deleting a drawing stored within a spatial DBMS is usually simple, but requires a few nuances due to the multi-user / multi-process nature of most DBMS servers. See the discussion in the Tech Tip in the Database Console topic.

**Projections and Spatial DBMS**

Given the different methods of storing drawings within a DBMS there is some variation as to how projection information is also stored. In general, when importing or linking drawings from spatial DBMS Manifold will acquire the correct projection to use for that drawing. For the sake of discussing projections, we can consider three types of drawings stored in DBMS:

- **Native drawings**, that is, drawings which use geometry types and metadata or projection codes specific to a particular spatial database. Examples include drawings stored as SDO_GEOMETRY within Oracle, ST_GEOMETRY within IBM DB2 with Spatial Extender, native PostgreSQL geometry or native SQL Server 2008 geometry.

- **ESRI drawings**, that is, drawings which use geometry types and metadata specific to a particular ESRI technology, which may or may not be tied to a particular database. Examples include SDE drawings stored within SQL Server using ArcSDE or ESRI Personal Geodatabases stored within Access .MDB. See the ESRI Geodatabases topic for information on using such geodatabases with Manifold.

- **Manifold drawings**, that is, drawings stored by Manifold within any DBMS using Manifold's generic spatial DBMS capability (or using the Manifold spatial extender with SQL Server), regardless of which geometry type is used. Examples include drawings stored by Manifold using OGC WKB within MySQL with a spatial index created by Manifold or drawings stored by Manifold using Manifold Geom within, say, SQL Server Express with a spatial index created by Manifold.

**Native drawings** store coordinate systems using means specific to that particular spatial database. Such means usually include a table or a set of tables which store the definitions of all coordinate systems together with a table storing the bindings between columns in the database tables which contain geometry data and their coordinate systems.

Manifold can handle native drawings within DB2, Oracle and PostgreSQL and SQL Server 2008 spatial. Exporting a native drawing from Manifold allows selecting a coordinate system from the list of those registered in the database and creates the binding between the geometry column in the exported table and that coordinate system. Manifold will attempt to match the coordinate system in use to a coordinate system supported by the spatial DBMS. If an exact match is not found, Manifold will re-project the data into the closest coordinate system (projection) found. Importing or linking a native drawing into Manifold reads the binding and retrieves the coordinate system.

For projections within SQL Server 2008 native GEOMETRY type, see the comments on SQL Server 2008 projections in the SQL Server Spatial DBMS Facilities topic.

**ESRI drawings** are similar to native drawings but are not tied to a particular type of a database except as supported by ESRI. For example, Personal geodatabases are usually encountered only in the form of Access .MDB files, and not all DBMS systems are supported for use with SDE. There is a table storing the definitions of all coordinate systems, and a table storing the bindings between geometry columns and coordinate systems. Importing or linking an ESRI drawing into Manifold reads the binding and retrieves the coordinate system. Both Personal and SDE geodatabases store coordinate systems using a format similar to the PRJ extension introduced by ESRI to support storage of projected data within shapefiles. As a result of years of experience
Manifold® System Release 8.00 User Manual

encountering many different variations of PRJ files Manifold is able to read virtually all coordinate systems encountered in either Personal or SDE geodatabases.

**Manifold drawings** are the simplest of all in that when Manifold exports a geometry type and creates a spatial index it also creates a table named `MFD_META` to host metadata used by Manifold. All metadata is stored by Manifold in the `MFD_META` table, including information about coordinate systems (projections) used. Exporting a Manifold drawing writes the coordinate system into `MFD_META`. Importing or linking a Manifold drawing reads the coordinate system from `MFD_META`.

In general, Manifold always writes the coordinate system used during export of a drawing and always reads the coordinate system in use when importing or linking.

**Projection Matching During Export**

Different spatial DBMS vendors support different collections of coordinate systems (projections), as does Manifold. When exporting a drawing to a spatial database, Manifold matches the coordinate system of the drawing to the closest coordinate system supported by the database. If the database does not support the exact coordinate system of the component, Manifold will re-project objects on the fly.

To know the coordinate system that will be assigned to the exported component, press the [...] browse button near the projection readout in the export dialog. Manifold will show a dialog with a list of coordinate systems supported by the database with the intended coordinate system selected.

Sometimes DBMS vendors will use different names for what are the same coordinate systems, or may not even use obvious names. For example, each coordinate system in a PostgreSQL database is assigned a unique identifier, called an **SRID** (Spatial Reference system ID).

When exporting a drawing to a PostgreSQL database, pressing the [...] browse button near the projection readout in the export dialog will show a list of supported SRIDs together with the selected SRID. For example, for **Latitude / Longitude** the SRID value is **4030**.

In another example exporting drawings to SQL Server 2008 spatial uses EPSG codes to represent coordinate systems, so the value reported will be the EPSG code for the coordinate system in use.

Manifold will do its best to come up with a reasonable name for a coordinate system, if possible. For example, loading a coordinate system from a PostgreSQL data source parses the name of the coordinate system from its definition within PostgreSQL. Unnamed coordinate systems used in databases will be assigned names synthesized from their IDs (SRIDs).

**Units of Measure in Linked or Imported Surfaces**

A limitation of Manifold's mechanism for storing surfaces in spatial DBMS is that the linked or imported surfaces are expected to represent heights in **meters**. If a linked or imported surface is generated using a data set in which heights are expressed in **feet** or some other unit, then the hill shading effect will be overly dark. The workaround to this is to convert surface heights to meters before export to a database if they are in feet, using the Surface Transform calculator or an intermediate query. See the Queries and Images or Surfaces topic for an example query that will do the trick.

**Notes**

The idea of storing geometry within non-native geometry types in databases applies to Manifold itself, since, after all, tables within Manifold are in fact a dedicated database system of sorts. That's why Manifold can store geometry in the form of **GEOMETRY**, a binary data type, within Manifold's own tables. It is also why Manifold has binary types for other commonly-encountered GIS binary blob storage types, including **GeomWKB** for OGC WKB, **GeomSHP** for ESRI shapefile geodatabases and **GeomSDE** for SDE binary data. The availability of all these types makes it easy to convert geometry data between binary type formats used by different systems.

**GeomSHP** and **GeomSDE** are somewhat similar approaches with differences in binary data organization. **GeomSHP** stores coordinates as double-precision floating point values. **GeomSDE** stores coordinates as integer values which are compressed using a simple run-length encoding scheme. The coordinate values must be scaled and shifted using the information stored in metadata tables.
Note that there are no vendor-specific, spatial DBMS geometry types like Oracle's SDO_GEOMETRY within Manifold tables because those types are constructs that occur within the spatial DBMS. Manifold GEOMETRY (Geom) data is automatically converted back and forth with the target spatial DBMS geometry data type on data exchange with the spatial DBMS. In contrast, the various Geom types supported within Manifold tables are not specific to any one DBMS but can exist wherever binary types are allowed.

Manifold allows simultaneous usage of multiple geometry types within the same DBMS. For example, an Oracle database could contain drawings stored using Oracle's own SDO_GEOMETRY type using Oracle's own spatial indices, and that same database could also contain drawings stored using Manifold's Geometry type using generic spatial indices created by Manifold. In theory, it could also store an SDE geodatabase using ESRI-style technology. When Manifold connects to that Oracle database it will correctly identify all technologies in use and utilize appropriate methods when importing the Oracle, Manifold or ESRI types from that database.

It may seem odd to want to connect to a spatial DBMS and store spatial data within that DBMS while not using the native geometry type provided by that DBMS. There are cases where that nonetheless makes sense. For example, we may have the budget for only one enterprise-class DBMS server installation within our organization, and we may have chosen Oracle for that DBMS with the idea of standardizing upon Locator with SDO_GEOMETRY (Oracle's native geometry type) for our spatial geometry needs. But we might have occasion to want to provide data for interoperability with some client software that does not understand SDO_GEOMETRY but which understands OGC WKB. In that case, we could connect to our Oracle server and choose the Manifold type of spatial storage using Geometry (WKB) to enable export to the DBMS of drawings that are stored using OGC WKB.

In fact, quite remarkably we can link drawings to Oracle using different connection technologies for different drawings. One drawing could be stored using Oracle's native geometry. Another drawing could be stored using Geometry (WKB) managed by Manifold. We can move objects into the OGC form by simply copying and pasting from one drawing to the other.

Technical Support

DBMS packages used for spatial DBMS work are highly complex software systems with many installation, configuration, operation and administration options. The tips above presume reasonably default configurations set up by administrators who are reasonably worldly about configuring DBMS installations in a portable and open way. Successful operation with the various spatial DBMS packages Manifold understands is not normally difficult, but can require significant DBMS and IT technical expertise from database administrators when DBMS installations become more elaborate. For example, permissions can be set in DBMS installations that may conflict with use of clients like Manifold. This will come as no surprise to the DBA with client integration experience.

Manifold does not support third party DBMS products, with the exception that current Express editions of SQL Server (2008 and 2005), Oracle and DB2 will be supported for Enterprise Edition use with those DBMS products in default configurations. See comments in the Database Installations topic. Although the manifold.net team is enthusiastic about working with other DBMS products, such as PostgreSQL, the great variability encountered in open source installations does not make it economically feasible to provide technical support services beyond the three major commercial DBMS products.

Developer level support incidents may be used for questions about Enterprise Edition features used with the three supported database products, but only for the actual Enterprise dialogs. For example a question about connecting with Enterprise Edition via Database Console to an Oracle data source will result in an answer limited to the use of a specific Manifold dialog, such as explaining the purpose of the Server, User Name and Password boxes.

Support does not extend to explaining how you can configure users in the DBMS, how to determine what server name is being used or should be used or how to determine whether a given user has connectivity to a given data source. Use a database consultant to assist with DBMS-centric issues. There are many ways a clever (or overly clever or not so clever) database administrator can configure such complex DBMS products to make it impossible for clients like Manifold to work with them with the full feature set of either client or server - that's what keeps database integration consultants in business!

Oracle Spatial DBMS Facilities
Oracle Spatial Facilities
Manifold Enterprise Edition provides built-in, highly-integrated facilities for working with Oracle databases using spatial DBMS technology. Manifold Database Administrator Edition also provides administrative capabilities used with Oracle database to enable and configure various Manifold features that may later be used from Enterprise Edition.

In particular, Manifold Enterprise Edition includes full support for use of Oracle's outstanding spatial technology, using either full Oracle Spatial licenses or simply via the Oracle Locator technology built into standard Oracle database products or, when available, Oracle's GeoRaster technology for storing images and other raster data. This topic provides an overview with links to other topics that discuss Oracle capabilities in detail.

Manifold is a complete, drop-in replacement for old-fashioned "middleware" as sold by legacy GIS vendors for Oracle Spatial applications. In many cases Manifold may be used as the user front end for Oracle Spatial applications or as the user interface, editing and visualization front end for geospatial data within standard Oracle databases (using Locator) without need to acquire and deploy Oracle Spatial licenses. Oracle's provision of core Oracle Spatial technology, such as the SDO_GEOMETRY type, within standard Oracle database versions makes it possible for enterprises to use Manifold to standardize on Oracle for all geospatial data needs in a highly flexible and efficient way.

Manifold support for Oracle spatial technology works throughout all of Manifold System, including the Manifold Internet Map Server and runtime license applications. Oracle spatial technology provides enterprises with an outstanding solution for geospatial data storage and exploitation. Manifold provides enterprises with a powerful and modern GIS front end to maximize their investment in Oracle through desktop GIS, Internet map serving or integration into custom applications.

Note that some Oracle products, such as Oracle Express Edition, may have Locator spatial capability but not provide GeoRaster capability. In that case Manifold can work with such Oracle products to save drawings but not images, which require GeoRaster capability.

Manifold Enterprise support for Oracle includes:

- **Oracle Call Interface (OCI) Integration** - OCI is the native Oracle interface for exchanging data. Using the native interface provides better performance and allows using features not exposed through generic database interfaces such as ODBC, OLE DB and ADO .NET. Use OCI when connecting to Oracle databases.
- **OCI Support for Tables** - Manifold can export, import and link table data read/write through OCI. SDO_GEOMETRY values are represented as Manifold native geometry values in the appropriate coordinate system. Manifold coordinate systems are automatically mapped to Oracle coordinate systems.
- **OCI Support for Drawings** - Manifold can export, import and link vector data (drawings) through OCI. Linked vector data sets (linked drawings) are read/write and are cached locally. This provides a superb user interface for working with spatial data within Oracle.

- **Dynamic Editing of Linked Drawings** - Manifold can dynamically display drawings created from SDO_GEOMETRY data within Oracle and allows use of the full range of interactive and programmatics Manifold tools, such as visual editing tools, transforms, adding/deleting/editing objects or table data and other Manifold features.

- **Multituser Drawing Editing with Version / Conflict Resolution** - Many users at the same time can edit the same drawing stored in Oracle. Manifold will automatically track the version of each object in case two users attempt to simultaneously edit the same object and will assist users in resolving any conflicts via the Review pane.

- **Import or Linking Drawings from Views** - Manifold drawings may be imported from or linked to Oracle views. Views are a very powerful way of extracting a portion of data using a query. See the Example: Storing a Drawing in Oracle topic for an example.

- **Area of Interest Windowing** - Users may import or link in only that part of an Oracle drawing or view that is within their area of interest. This allows storage of immensely large drawings in Oracle yet allows practical usage of a portion of such drawings. *Note:* Import or linking a drawing using an area of interest from a view assumes the view has a spatial index.

- **OCI Support for Rasters / Images** - Manifold can import, link and export raster data (images) with Oracle products that include GeoRaster technology. Linked raster data sets (linked images) are fetched from the database on the fly preserving coordinate information. Manifold can work with a variety of images stored in Oracle, including interleaved channel images, indexed (palette) images and other types. Manifold can import as a surface a single channel of an image stored in Oracle.

- **Export and Import of Surfaces** - Manifold can export surfaces to Oracle as GeoRasters and can also import surfaces stored as Oracle GeoRasters (however, Manifold releases up to and including 7.00 cannot link surfaces from Oracle GeoRasters). Export to Oracle and import from Oracle of images is similar to the export and import of images. See the Example: Storing an Image in Oracle topic for the process used both for images and surfaces.

- **Automatic Read / Write of SDO_GEOMETRY** - SDO_GEOMETRY is the fundamental data type used within Oracle spatial technology to store drawing objects. When exchanging data with Oracle data sources via OCI, Manifold automatically maps Manifold geometry columns into Oracle SDO_GEOMETRY data and vice versa.

- **Drawing Export to Oracle Databases** - Manifold can export drawings directly into either Oracle Spatial databases or into regular Oracle databases using Locator. Tables will automatically be created using SDO_GEOMETRY data for drawing objects and other data types for attributes. Manifold will automatically preserve projection information and will create a spatial index for the drawing. This facility is a great way of loading data into Oracle spatial databases.

- **Oracle Projections Support** - Importing or linking a raster or vector data set from an Oracle database brings the coordinate system of the data set into Manifold, which supports all Oracle coordinate systems. Exporting a vector data set from Manifold to an Oracle database lets the user select the coordinate system to use from the list of coordinate systems supported by the database. By default, Manifold selects the coordinate system available with Oracle which is the best match for the coordinate system of the data set, making any required coordinate system translation on the fly. Manifold recognizes Oracle coordinate systems defined through parameter tables as well.

- **Custom Database Console Support** - When connecting to an Oracle data source through OCI, the Database Console provides a variety of special Oracle features, such as using drawing icons to show tables that contain drawing geometry data, not available with other data sources. The Open Data Source command provides a rapid way to open the Database Console for components that are linked from an Oracle data source. *Note:* because the Database Console provides a more convenient user interface for browsing Oracle databases, we will almost always use the Database Console to import or link components from an Oracle database instead of using the File - Import or File - Link menu commands.

- **Database Administrator Edition** - Database Administrator Edition includes a powerful managerial console called the Administrator Console that enables IT and DBMS administrators to configure data sources used to store the enterprise's geospatial data. The Administrator Console allows administrators to configure GIS data storage within the data source so that the data source is easier and more convenient to use for ordinary GIS users. Database Administrator Edition also includes the Tools - Batch Export tool that facilitates rapid, mass uploading of Manifold drawings, images and surfaces into Oracle spatial databases.

The above dedicated capabilities are just the beginning of Manifold support for Oracle. Oracle's spatial technology provides enterprise-class geospatial database capabilities with unprecedented sophistication and power. Future editions of Manifold will extend and deepen Manifold's commitment to Oracle support, adding new capabilities at a rapid pace.
Manifold supports all Oracle projections (coordinate systems) although Oracle does not support all Manifold projections. When a component is imported or linked from an Oracle database it will automatically use that same projection within Manifold.

When a component is exported from Manifold to Oracle, Manifold will automatically choose the Oracle projection that is the best match, that is, the most similar to, the Manifold projection in use. Manifold export dialogs will report the degree of similarity between the Manifold projection and the proposed Oracle coordinate system. If need be, Manifold will re-project the component on the fly into that Oracle projection system as part of the uploading process.

There are two nuances of interest in the case of components using a coordinate system that appears both in Oracle and in Manifold (that is, all Oracle coordinate systems):

- Although Manifold supports all coordinate systems used by Oracle, sometimes the names used for those coordinate systems are different. For example, the Latitude / Longitude projection used in Manifold is known as the TWD97 projection in Oracle when using the WGS 84 datum (the default for Latitude / Longitude).
- Manifold defines coordinate system presets using higher-precision parameters than those used in Oracle so even if the coordinate system is otherwise identical the Manifold settings have to be lowered in precision to match those used by Oracle. Manifold understands such precision-matching requirements when identifying the equivalent projection in Oracle and will automatically re-project data to account for precision differences. If this or any other re-projection is not desired, Manifold provides a Do not project data option (off by default) that may be checked on to prevent any re-projection of data.

It should be emphasized that the second point above is an example of “overkill” accuracy on Manifold’s part and in no way is any practical limitation of Oracle.

**Frequently Asked Questions**

**Must I install something extra to get Oracle spatial capability in Manifold?** - No, not if you have Enterprise Edition installed (including Universal Edition and Universal Runtime). If you do not have Enterprise Edition or higher installed you will not be able to use Oracle spatial capabilities from within Manifold System.

**Must I use Database Administrator Edition to get Oracle spatial capability in Manifold?** - Strictly speaking, no, although it will be a very rare organization that will not acquire a few Database Administrator Edition licenses to support Manifold use with Oracle. Database Administrator Edition is required to “turn on” certain Manifold features such as friendly names and storage of drawing formatting within the database. Database Administrator Edition also provides conveniences such as batch upload of components and presets for imports and links that make life easier both for administrators and for ordinary users. If you are willing to do without the features and conveniences enabled for all users (including those using Enterprise Edition) by Database Administrator Edition then you could use Enterprise Edition only.

**What versions of Oracle can I use? Must I use Oracle Spatial?** - Manifold works with Oracle Spatial as well as other Oracle editions that include Locator (such as Oracle Express Edition) or GeoRaster (such as Oracle Enterprise Edition) capability.

**Must I install a Manifold license on my Oracle server machine?** No. Manifold is a client application that connects directly to the Oracle database server without needing any "middleware" or "server" piece of Manifold on that Oracle server. For example, you could have Oracle running on one or more server machines and then have Manifold installed on a few hundred client machines where operators are doing GIS. You need to install a Manifold license on the client machines, but you do not need to install Manifold licenses on the Oracle server machines. To take another example, suppose you had a web server hosting a web site that involved connections to an Oracle database on a different machine. If you had a GIS-enabled web site running on that web server machine using Manifold IMS you would need a Manifold license for that web server machine so that Manifold IMS could run. But, you would not need a Manifold license for the Oracle server machine.

**Is Manifold’s use of Oracle Spatial compatible with other applications?** Yes, if those other applications work directly with Oracle using standard Oracle interfaces and technologies. For example, if you load an Oracle Spatial database with vector data by exporting a drawing from Manifold any other application that knows how to work with Oracle Spatial databases will be able to use that vector data.

**Manifold runs in Windows - can I run my Oracle server on Linux?** Of course. Manifold is happy to connect to your Oracle data sources regardless of what operating system they use.
Does Manifold require ArcSDE to be able to connect to Oracle Spatial? No. Manifold requires no middleware or other software of any kind to be able to connect to Oracle databases. Manifold connects directly to Oracle data sources using the Oracle Call Interface (OCI).

Can Manifold connect to Oracle Spatial through ArcSDE? No, and there is no need to do so. Manifold works directly with Oracle Spatial. ESRI's ArcSDE is middleware designed to keep ESRI customers locked into ESRI products whether they like it or not. Manifold connects directly to Oracle and neither requires nor uses ArcSDE. Some customers who are stuck with ArcSDE applications for legacy reasons will no doubt continue to use ArcSDE; however, they can also use applications like Manifold to connect directly to the centralized Oracle Spatial database in addition to whatever they are doing via ArcSDE.

So Manifold is "DBMS-centric" rather than "GIS-centric?" For enterprises, yes. Clearly, if you have vast amounts of corporate data held within a supremely capable DBMS like Oracle your enterprise is DBMS-centric and darn well should be. It's madness to allow any GIS vendor to attempt to interpose itself as some sort of proprietary standard that interferes or limits in any way your ability to leverage your Oracle installations. While it's certainly true that some corporate processes involve such a high degree of specifically GIS functionality (such as heads-up digitizing of new parcels in a parcel map) that those particular processes are clearly GIS-centric, it is important to keep in mind that such processes are adjuncts to the core DBMS. They are simply examples of the rich extensibility and connectivity that a well-founded DBMS-centric geospatial data storage architecture allows. Manifold is committed to using native Oracle standards and technology as the guarantee of broad compatibility with many other applications and products. If Oracle standards are the touchstone, you can confidently deploy tools like Manifold knowing your core investment into Oracle will be protected.

Do Manifold queries execute locally or on the Oracle server? Queries written in the Database Console execute on the Oracle server. Other Manifold queries in your Manifold project will execute locally within Manifold spatial SQL. This means that if they involve data brought in from an Oracle database (such as if they involve a linked table) there will be a performance hit because data must be brought in from the Oracle server to allow the query to operate. We anticipate that future Manifold editions will extend the capabilities of Manifold's query processor so that queries will automatically be analyzed and those parts of the query that can be dispatched to run in the Oracle server will be run on the server.

Acknowledgements

The manifold.net team would like to thank Oracle for its support of independent software developers working to integrate products with Oracle. The Oracle Technology Network is a model of how a technology leader like Oracle encourages developers to undertake large engineering projects with confidence. This provides better integration and better value for Oracle users worldwide. Special thanks go out to the Oracle Spatial team in New Hampshire as well as to Oracle staff in California.
Installing Oracle

Manifold users will often use Oracle database products in conjunction with Manifold System. In particular, Manifold Enterprise Edition users will take advantage of Oracle Spatial Facilities that are provided within Enterprise Edition to store drawings and images within Oracle servers.

This topic provides a summary of installation procedures that may be used to install Oracle products for use with Manifold. Two products are covered: Oracle 10g Express Edition and Oracle 10g Enterprise Edition. In addition, Oracle Client software should be installed on machines that will be working with Oracle databases. The client software need not be installed on the machine on which the Oracle Express or Enterprise server software is installed. These software packages may be downloaded at no charge from Oracle’s web site and used to develop applications.

The following summaries have been written for installation on a Windows XP SP2 machine using Oracle versions that were downloadable at the time of this writing. Procedures for Windows Server 2003 and for newer Oracle editions will be very similar.

To install Oracle 10g Express Edition (10.2.1.0):

1. Close all running applications.
2. Start the installation of Oracle 10g Express Edition by launching OracleXE.exe in the Oracle installation files folder.
3. In the welcome screen click Next.
4. In the license screen read through the license and then click I accept the terms in the license agreement, and click Next.
5. In the destination location screen accept the default folder suggested for installation or specify a different folder if desired and click Next.
6. In the password screen enter a password string in the Enter password text box. Enter the same string in the Confirm password text box, and click Next. Write down the password you used.
7. In the summary screen note the port numbers used (For example, Oracle database listener: 1521, Oracle Services for Microsoft Transaction Server: 2030, HTTP listener: 8080), then click Install.
8. Wait until the installation completes.
9. In the installation complete screen click Finish. Close the database portal page, if you have any open.

Configuring Windows Firewall (This continuation of the installation is not necessary if you are not planning to access this instance of Oracle from other machines or if the firewall is turned off.)

10. Launch the Windows Control Panel.
11. Double click the Windows Firewall icon.
12. Switch to the Exceptions page. Click Add Port. Set (that is, enter) the name to Oracle Listener. Set the port number to the value noted in step 9 above (for example, 1521). Click TCP. Click Change Scope. Click My network (subnet) only. Click OK to close the Change Scope dialog. Click OK to close the Add Port dialog.
13. Click OK to close the Windows Firewall dialog.

After following the above steps it is easy to test that an Oracle Express installation is functional by using the Database Console in Manifold to quickly connect to Oracle. The following set of instructions assumes we are running Manifold on the same machine on which Oracle has been installed.

Connecting to an Oracle Express Installation:

1. Launch Manifold and launch the Tools - Database Console command.
2. Press the [...] browse button to the right of the Data source box to launch the Data Sources dialog.
3. Create a connection to Oracle Express and connect to it as given in the example in the Data Source Dialog topic.

Once a connection has been made to Oracle Express with Database Console as above the Data source string will remember that connection. Administrator Console (if we have Database Administrator Edition installed) will also remember that connection for the dialog's Data source.
To install Oracle 10g Enterprise Edition (10.2.0.1):

1. Close all running applications.
2. Start the installation of Oracle 10g Enterprise Edition by launching SETUP.EXE in the Oracle installation files folder.
3. In the installation method screen select Basic Installation. Set installation type to Enterprise Edition. Note the database name (orcl). Enter a password string in the Enter password text box. Enter the same string in the Confirm password text box, and click Next.
4. In the prerequisite checks screen click Next.
5. In the summary screen, click Install.
6. Wait until the installation completes.
7. In the database configuration assistant screen that pops up during the installation, click OK.
8. If you get a Windows Security Alert box asking whether or not you want to block java or javaw, click Keep Blocking.
9. At the end of the installation screen click Exit. In the confirmation dialog click Yes.

Configuring Windows Firewall (This continuation of the installation is not necessary if you are not planning to access this instance of Oracle from other machines or if the firewall is turned off.)

10. Launch the Windows Control Panel.
11. Double click the Windows Firewall icon.
12. Switch to the Exceptions page. Click Add Port. Set (that is, enter) the name to Oracle Listener. Set the port number to the value noted in step 9 above (for example, 1521). Click TCP. Click Change Scope. Click My network (subnet) only. Click OK to close the Change Scope dialog. Click OK to close the Add Port dialog.
13. Click OK to close the Windows Firewall dialog.

To install the full version of Oracle client software and configure it connect to an instance of Oracle (not required if Manifold is used on the server machine):

1. Close all running applications.
2. Start the installation of Oracle 10g Client by launching SETUP.EXE in the Oracle installation files folder.
3. In the welcome screen click Next.
4. In the installation type screen select Custom and click Next.
5. In the home details screen specify the installation folder or accept the default and click Next.
6. In the product components screen check Oracle Call Interface, Oracle Net as well as any other components you want to install and then click Next.
7. In the prerequisite checks screen click Next.
8. In the summary screen click Install.
9. Wait until the installation completes.
10. In the welcome screen of the Oracle Net Configuration Assistant that comes up at the end of the installation process, be sure the Perform typical configuration box is unchecked and click Next.
11. In the naming methods screen of the assistant click Next.
12. In the service name screen of the assistant specify the service name as the database name you used when installing an instance of Oracle (by default, xe for Express Edition and orcl for Enterprise Edition), and click Next.
13. In the protocols screen of the assistant select TCP and click Next.
14. In the TCP / IP configuration screen of the assistant specify the host name as the name of the machine running Oracle and click Next.
15. In the test screen of the assistant click Yes, perform a test and click Next. If the test does not succeed (if it fails the text output will contains the phrase "The test did not succeed."), click Change Login and supply a valid user name (system) and the password you used when installing the instance of Oracle and click OK. After the test succeeds click Next.
16. In the net service name screen of the assistant specify the net service name as something memorable, such as oracledb and click Next. You will use this name when connecting to this database from Manifold and other applications.
17. In the another net service screen of the assistant click No and then click Next.
18. In the done screen of the assistant click Next.
19. In the second done screen of the assistant click Next.
20. In the final done screen of the assistant click Finish.
21. In the end of installation screen click Exit. In the confirmation dialog click Yes.

To install Oracle Instant Client and configure it to connect to an instance of Oracle (not required if Manifold is used on the server machine):

(This process is also described in the readme file in the archive of installation files downloaded for Oracle client software.)

1. Create a new folder (for example, C:\Oracle) and unzip the archive into this folder.
2. Set the system PATH environment variable to include the path to the folder.
3. Set the system TNS_ADMIN environment variable to point to the folder.
4. Create a new blank text file and enter the following text:

   localservice=
   (DESCRIPTION=
     (ADDRESS_LIST=(ADDRESS=(PROTOCOL=TCP)(HOST=server)(PORT=1521)))
     (CONNECT_DATA=(SERVICE_NAME=remoteservice)))

   Replace localservice with the name to use for the database connection on the machine to which you are installing Instant Client, server with the name of the machine hosting the instance of Oracle you will use, and remoteservice with the name of the database to connect to on that machine (for example, xe if it is the default database name for Oracle Express Edition or orcl if it is the default database name for Oracle Enterprise Edition).
5. Save the text file as TNSNAMES.ORA in the folder created in step 1.

To connect to an Oracle database using Manifold:

1. Set up a connection to the desired database using either the full version of Oracle client software or Oracle Instant Client. This step is not required if Manifold is used on the server machine.
2. Launch Manifold.
3. Launch Tools - Database Console.
4. Click the Browse button to connect to the Data Source dialog.
5. In the Data Source dialog create a connection to the desired Oracle database and connect to it following the example given in the Data Source Dialog topic. When specifying the server name in the in the Oracle Data Source dialog that appears as part of specifying an Oracle data source in the Data Source dialog, specify as the server as:
   a) The Windows computer name of the machine being used if Manifold is being used on the server machine. For example, if the Windows Control Panel, System applet's Computer Name tab says the name of our machine is gisfiles that is what we would use.
   b) If Manifold is being used on a client machine that is different from the server machine, the name of the database connection as configured in the Oracle client in use. For example, oracledb if we follow the above example for installing the full version of Oracle client software or localservice if we follow the above example of installing Oracle Instant Client and haven't bothered to change the connection name from "localservice". Note: the default server name used for Oracle Express installations is xe and is not oracledb. This is an important detail that is different between Oracle Express and Oracle Enterprise editions.

Note that in the above procedures, although there are the expected dialogs to go through for installing Oracle software as there would be for any big-time application with sophisticated options, once the installation is done it is very easy to connect to Oracle from Manifold. Manifold will remember the data source used in both the Database Console and (if Database Administrator Edition is installed) the Administrator Console.

Adding Users to Oracle
For security and administrative control, it is a good idea to create user logins for an Oracle database so that users can access the database without having to connect using Administrator logins such as `system`.

For Oracle XE and other Oracle products, Oracle provides a convenient Database Control facility running over local web pages that may be used to add users. Launch the Database Control from the Windows Start button, drilling down through All Programs to the Oracle program choices. After logging into the Database Control using the `system` administrator login we can go to the Administration tab and drill down into the Users page. Click the Create button to launch the Create User page.

In the General tab, provide a Name and Password for the user and choose a Default Tablespace (such as USERS) and a Temporary Tablespace (such as TEMP) for the user.

In the Roles tab, the user must have a CONNECT role, which is provided by default.

In the System Privileges tab, the user must have CREATE SEQUENCE, CREATE TABLE and CREATE TRIGGER privileges. Click the Edit List button and add these privileges.

In the Quotas tab, the user must be allowed to use sufficient space for their storage requirements. Many DBMS administrators in small organizations will give users Unlimited quotas for USERS and TEMP tablespaces. This is somewhat trusting of users, but in an era of very large hard disks and reasonably sensible users it often is easier to simply grant unlimited usage than it is for relatively inexpert DBMS administrators to worry about managing storage space quotas.

Press OK to create the user. We can then use that user login to connect to the DBMS. Each login that uses the USERS tablespace will be able to see drawings or images stored in the DBMS by other such logins.

DBMS administrators will find that Oracle has many first-rate facilities for organizing databases and user access. Such facilities are beyond the scope of this documentation but are well-covered by Oracle documentation and educational resources.

Example: Storing a Drawing in Oracle

In this example we export a drawing to an Oracle database and then we link it into a Manifold project. This example requires Manifold Enterprise Edition for Oracle Spatial capability and also requires an Oracle server that includes Locator capability, such as Oracle Spatial, Oracle Express Edition or Oracle Enterprise Edition.

In addition to showing the mechanics of uploading a drawing into Oracle Spatial and linking a drawing from Oracle Spatial, this example also shows off Manifold's ability to dynamically, visually edit drawings that are stored within Oracle Spatial, even within a multi-user editing environment.

Although of course Manifold also supports use of SQL to edit and otherwise manipulate drawings within Oracle Spatial, it's nice to know that if we prefer visual, interactive, mouse and command based editing to work with our Oracle Spatial data we can apply the full power of interactive Manifold editing just as if the drawing was a local part of our Manifold project.

Step 1: Export the Drawing to Oracle

We will use the example drawing of province boundaries in Mexico provided on the Manifold downloads site and used in various topics in the Examples chapter such as the Turning Layers Off/On by Zoom topic.

Our project contains just this single drawing. To upload it into an Oracle server we either right click on the drawing in the project pane and choose Export, or with the focus on the opened drawing window we choose File - Export - Drawing. In the resulting Export Drawing dialog we choose Databases () in the Save as type box. This launches the Data Source dialog.
If we have not yet created a connection to the Oracle server desired, we do so using the instructions in the example in the Data Source Dialog topic. When the data source is created we click on it to highlight it and press OK.
In the **Export Drawing** dialog we change the **Type** to **Oracle** to save the drawing using native Oracle Spatial geometry (as opposed to generic Manifold spatial storage using some other geometry type).

We will use default settings and export all of the checked columns with the drawing to Oracle. If we scrolled farther down into the **Columns** panel we would see that intrinsic columns are not checked by default. We could also note that neither the **ID** column nor the **Geom(I)** column appear because both are automatically exported to Oracle in all cases.

**Note:** Oracle supports only one variable-length column (such as binary data variable length or ANSI text variable length columns, for example) per table. If more than one of the columns to be exported is a variable-length column the exporter will complain and ask us to convert some of those columns into a different type (for example, we could convert them into fixed-length columns).

We press **OK** to upload the drawing. Uploading such a small drawing is fast. When the dialog finishes, we can see if there is indeed a new drawing exported into our Oracle server by using the Database Console to take a look at what is in the server.

**Step 2: Find a Drawing Stored in an Oracle DBMS**

We launch Tools - Database Console to launch the database console dialog.
The dialog remembers the last-used data source. We press the Refresh toolbar button to connect to the Oracle data source.

Whoa! What’s all that? When the database console connects to an Oracle server it shows us all the database objects in that server. If we connect to an Oracle Enterprise Edition server that has been installed with the full set of Oracle examples there will already be many objects containing geometry in that server. An actively used Oracle server can easily contain thousands of database objects.

However, lucky for us Manifold provides a Filter box that allows us to display only those objects of interest.
We can enter whatever characters we like in the Filter box to filter the view to only those objects that contain that exact string in their names. As we begin to enter characters, Manifold will begin searching and filtering the view (no need to press Enter - just type the filter string). Note that the Filter pattern is case-insensitive, so we can rapidly write what we like without needing to use the SHIFT key.

As we enter the Filter string, the view display reduces down to only the two database objects that contain the Filter string. Note that the top object has a Manifold drawing icon displayed, so we know it is something that can be imported or linked into a Manifold project as a drawing.

**Note:** In most Manifold installations using Oracle there will be one or more DBMS administrators who can use Database Administrator Edition to configure friendly names (also called component names) like those used for regular Manifold components in Manifold projections. If friendly names have been configured for a database then Database Console will automatically configure itself to use friendly names and we won’t have to wade through so many database objects that are not of interest.

However, even in that case there can be hundreds or even thousands of Manifold components stored in an Oracle database so the Filter box will still come in handy.

**Step 3: Link a Drawing Stored in an Oracle DBMS**

We can either import the drawing from the Oracle database, or we can link to it to create a dynamic, linked drawing in the project. We will link the drawing, as this keeps the drawing stored in the Oracle server with a dynamic representation of the drawing appearing in the local project.
To do so, we click on the drawing name to highlight it and then we press the **Link** button. We then press the **Close** button to close the database console.

When we do so, a new linked drawing appears in Manifold in the project pane. In this example, we linked the drawing right back into the same project from which we exported the drawing, but we could have just as easily closed Manifold and linked this linked drawing into a new project or into any project. The linking process is almost instantaneous.

**Note:** If Database Administrator Edition has been used to pre-configure import and link options for a component the component will link without any intermediate dialogs raised. If the component has not been pre-configured with options for us then a dialog with link options will be raised to allow us to specify any options desired.

**Step 4: Edit a Linked Drawing Stored in an Oracle DBMS**

We can click open that linked drawing and work with it as we might any other drawing. Let us do some editing using **smart mouse editing** moves as set forth in the Editing Objects topic, with which we assume the reader is familiar.
For example, we can **CTRL-ALT** click onto an object in the drawing to select it for editing. In the illustration above we **CTRL-ALT** click onto the province of Durango.

Selecting an object for editing in a Manifold drawing creates editing handles at the coordinates that define the geometry of the object. We can then drag those handles to re-shape the object, or do other cool things with them. For example, if we **SHIFT** click and drag a handle we move the entire object.
Let's **SHIFT** click and drag one of the editing handles on Durango and move the province to the Northeast out into the ocean.

When we release the **SHIFT** click and drag the province moves to the new location. We can then click anywhere in the drawing to deselect the object.
Like magic, there Durango is out in a new home as an island. The really amazing thing about this is that as we edit the drawing we are actually working with data stored not in the local Manifold project but brought into Manifold dynamically from the Oracle Server. Changes to the drawing are committed to the Oracle server as soon as they are accomplished.

**Step 5: Edit a Linked Drawing’s Table**

If we like, we can even make changes to the drawing’s table as well. Just as we can change the geometry of objects (that is, their shapes), we can change their data attributes as well.

![MEXICODRAWING Table](image)

<table>
<thead>
<tr>
<th>ID</th>
<th>ID 2</th>
<th>SQMI</th>
<th>PLACE_NAME</th>
<th>SQKM</th>
</tr>
</thead>
<tbody>
<tr>
<td>39</td>
<td>1</td>
<td>26635.63</td>
<td>SAN LUIS POTOSI</td>
<td>63068</td>
</tr>
<tr>
<td>40</td>
<td>2</td>
<td>32009.10</td>
<td>ZACATECAS</td>
<td>73252</td>
</tr>
<tr>
<td>41</td>
<td>3</td>
<td>52374.05</td>
<td>DURANGO</td>
<td>12318</td>
</tr>
<tr>
<td>42</td>
<td>4</td>
<td>76106.63</td>
<td>SONORA</td>
<td>182050</td>
</tr>
<tr>
<td>43</td>
<td>5</td>
<td>23603.34</td>
<td>SINALOA</td>
<td>58328</td>
</tr>
</tbody>
</table>

We click open the table and then double-click into the **PLACE_NAME** cell for Durango to change the name. [This illustration shows an example table where we have dragged this column leftwards in the table so the illustration can be smaller and still show the column.]

![MEXICODRAWING Table](image)

<table>
<thead>
<tr>
<th>ID</th>
<th>ID 2</th>
<th>SQMI</th>
<th>PLACE_NAME</th>
<th>SQKM</th>
</tr>
</thead>
<tbody>
<tr>
<td>39</td>
<td>1</td>
<td>26635.63</td>
<td>SAN LUIS POTOSI</td>
<td>63068</td>
</tr>
<tr>
<td>40</td>
<td>2</td>
<td>32009.10</td>
<td>ZACATECAS</td>
<td>73252</td>
</tr>
<tr>
<td>41</td>
<td>3</td>
<td>52374.05</td>
<td><strong>DURANGO NORTE</strong></td>
<td>12318</td>
</tr>
<tr>
<td>42</td>
<td>4</td>
<td>76106.63</td>
<td>SONORA</td>
<td>182050</td>
</tr>
<tr>
<td>43</td>
<td>5</td>
<td>23603.34</td>
<td>SINALOA</td>
<td>58328</td>
</tr>
</tbody>
</table>

Since we have dragged Durango more or less Northward in the drawing and further, since we know the Spanish for “North” but not for “Northeast” we will rename the province to **DURANGO NORTE**.
Press Enter and the edit to the table cell happens. To commit these changes to the server, we save the project.

**Step 6: Multiuser Viewing and Editing**

As mentioned before, the cool thing about all this is that we are editing Oracle data stored within our Oracle server, which could be accessed simultaneously by tens, hundreds or even millions of other people.

For example, we could open a second Manifold session on our machine, or someone else on some other machine that can access the same Oracle server could open a Manifold session on their machine and also link in the very same Mexico drawing we are using.

When they link in the drawing and open it (the illustration above shows a different Manifold session going on at the same time as the session in which the example was done), they will see that in this particular drawing of Mexico the province of Durango is indeed out to sea.

**Step 7: More Editing**

In either session of Manifold we can do even more dramatic editing than simply moving objects. We can add them or delete them or do whatever else we like.
We can click on Durango to select it and then press the **Delete** key.

It's gone! No more Durango Norte in the ocean. If we like, we can create a new object.
Using the Insert Area command, we can draw a triangular area free hand.

The new area appears in our drawing.

| 72 | 35 | 22205.42 | CAMPECHE | 50812 | 57 |
| 73 | 36 | 2445.07  | COLIMA   | 5191  | 42 |
| 74 | 37 | 2145.36  | MORELOS  | 4950  | 11 |
| 75 | 38 | 653.44   | DISTRITO FEDERAL | 1499 | 82 |
| 76 | 39 | [Isla Manifolds] |

We click open the drawing's table and see that the last row in the table (added when an object was added to the drawing) has no values. We'll add a name for our new island object. Changes made to the table will be committed to the server as soon as they are made.

Going back to our other session of Manifold we can choose View - Refresh Data to update any open windows with the latest changes. As expected, we see that Durango has been deleted and a new triangular area has been added to the drawing.
This example is deliberately made simple. However, in real life we could use linked drawings stored in Oracle databases for applications such as maintaining real estate parcel drawings for cities and towns. A city could centralize its geospatial storage within an Oracle database where many different applications and business processes could use that data.

As the data needs changing, such as when parcels are subdivided or changed, the data can be edited interactively using Manifold by those who have access permissions to do so. Those changes will be available to all Manifold sessions linking to that Oracle database. For example, a Manifold IMS web page could include a drawing layer linked from that Oracle database. Changes made to objects in that Oracle database will immediately be reflected in what that web page displays.

Note

The default name of the identity column used when exporting a drawing to an Oracle database is **OID** to avoid naming collisions with the **ID** column that stores Manifold object IDs in Manifold drawings.

If we have Database Administrator Edition we can use the Tools - Batch Export command to export many drawings at once to Oracle.

**Tech Tip: Deletions in Database Console**

It's easy to delete unwanted database tables by writing a drop table query in the query pane at the bottom of the Database Console.

```
drop table SYSTEM.US_MAIN
```

Simply enter `drop table` and then double-click on the table (drawings and other images are stored as tables in Oracle) in the upper pane to add that name to the query without need to manually enter it. Press the ![run button](image) to launch the query and the table will be deleted. Note that the upper list of objects in the database will not be refreshed to show the deletion until we press the ![refresh button](image).

Deletions of spatial components such as drawings are more complex than simply deleting a table. See the discussion in the Database Console topic.

**Tech Tip: Using Views**

One outstanding advantage of using Oracle to store drawings is that we can use the server-side power of the database to grab subsets of data by using Oracle Views. We can create a view by using a CREATE VIEW statement in Database Console and then link to that view.

A view is simply some SQL that grabs a desired subset of objects. For example, the following SQL will return all objects in `mydrawing` within a rectangle from (20, 30) to (120, 130):

```
--SQL
SELECT * FROM mydrawing WHERE SDO_FILTER(mydrawing.geom,
  SDO_GEOMETRY(2003, NULL, NULL,
  SDO_ELEM_INFO_ARRAY(1, 1003, 3),
  SDO_ORDINATE_ARRAY(20, 30, 120, 130))) = 'TRUE';
```

Using SQL statements in Database Console we can create a view in a way that makes it ready for use as a subset of a drawing in Manifold.
For example, suppose we have a latitude / longitude drawing called world that has been exported from Manifold. We would like to create a view called worldview that shows only those objects covered by a rectangle between latitude 20 and 30 and between longitude 120 and 130.

To be able to change and delete existing objects as well as edit new objects we must also specify the view has a primary key and also enter the view into the geometry metadata table.

To specify the view has a primary key we could use:

```sql
--SQL
CREATE OR REPLACE VIEW worldview(oid PRIMARY KEY DISABLE NOVALIDATE, version, geometry) AS
SELECT * FROM world WHERE SDO_FILTER(geometry, SDO_GEOMETRY(2003, 2000097, NULL,
  SDO_ELEM_INFO_ARRAY(1, 1003, 3), SDO_ORDINATE_ARRAY(20, 30, 120, 130))) = 'TRUE'
```

To enter the view into the geometry metadata table we could use:

```sql
--SQL
INSERT INTO USER_SDO_GEOM_METADATA VALUES('worldview', 'geometry',
  MDSYS.SDO_DIM_ARRAY(
    MDSYS.SDO_DIM_ELEMENT('Longitude', -180, 180, 1),
    MDSYS.SDO_DIM_ELEMENT('Latitude', -90, 90, 1)), 2000097)
```

Given just the above SQL, any newly added objects will not become editable until we do a View - Refresh Data command. To enable newly added objects to become immediately editable we have to create a synonym for the sequence that is used to produce unique keys for the drawing so that this sequence is available in the view as well:

```sql
--SQL
CREATE SYNONYM worldview_seq FOR world_seq
```

The above example illustrates a view containing objects covered by the specified latitude and longitude extents. We could, of course, write the SQL however we desire to select specified objects using whatever criteria we like. For example, suppose our drawing shows oil wells that have a date attribute that specifies when the well was drilled. We could create a view that showed only those wells drilled between desired dates.

Tools - Database Console
Tools - Batch Export
Example: Storing an Image in Oracle

In this example we export an image to an Oracle database and then we link it into a Manifold project. This example requires Manifold Enterprise Edition for Oracle Spatial capability and also requires an Oracle server that includes GeoRaster capability, such as Oracle Spatial or Oracle Enterprise Edition. To export an image into an Oracle Spatial database we must have access to that database and have write permissions. The process set forth in this topic also works for exporting surfaces to Oracle GeoRasters as well.

Oracle Express Edition does not include GeoRaster capability so this example will not work with regular Oracle distributions such as Oracle Express. Oracle does make it possible for people to download for test and evaluation free copies of Oracle products that do include GeoRaster capability. See the Oracle web site for the latest information on such free downloads. See the Export Image - Oracle topic for notes on the Export Image dialog as used with Oracle. See the notes at the end of this topic for a Manifold solution to storing images within regular Oracle distributions.

This example assumes the reader is familiar with Manifold images. See the Images and subsequent topics for details on Manifold images.

**Step 1: Export the Image to Oracle**

We begin with the SanFran example image that may be imported from the SanFran.jpg sample file on the Manifold downloads site. This is an RGB image that is 1514 x 1440 pixels in size.

To export an image to an Oracle database:

1. Open the image in an image window.
2. Choose File - Export - Image from the main menu.
3. In the Export dialog choose Data Sources () in the Save as type box.
4. Connect to the desired Oracle data source, creating a data source for the Oracle server desired if one has not already been created in the Data Source dialog.
5. Provide the information required in the Export Image dialog. Choose Oracle in the Type box to export using Oracle GeoRaster if available. Choose Manifold in the Type box to use Manifold image storage within the database. Check the other options as desired.
6. Press OK.
In the illustration above we have connected to an Oracle server that was named Oracle Spatial Server in the Data Source dialog. We have chosen Oracle in the Type box to use Oracle’s native GeoRaster technology.

Note: If we want to manually choose settings for GeoRaster storage in Oracle we can click the [...] browse button to the right of the Name box to launch the Oracle Image Name dialog. See the technical note at the end of this topic for more information.

We use default settings for this dialog, accepting the recommended defaults such as checking the Create pyramids box. This creates additional views of the image at different scales and stores them into the Oracle database so that later on when we retrieve the imager and view it as we zoom in and out of the image there will be redundant views to make the zoom process look faster. It's a very good idea to create pyramids, especially for large images, so don't uncheck this default unless you like slow and unresponsive images. Press OK.

Uploading such a relatively small image is fast. When the dialog finishes, we can see if there is indeed a new image exported into our Oracle server by using the Database Console to take a look at what is in the server.

Note: Export of images to Oracle is robust. For example, exporting an image to Oracle as a tiled table correctly rolls back all changes upon a failure.

**Step 2: Using an Image Stored in an Oracle DBMS**

We launch Tools - Database Console to launch the dialog and then we press the Refresh toolbar button to connect to the Oracle server. The dialog remembers the last-used data source for us.
Our Oracle server happens to be loaded with hundreds of items, so we enter *sanfran* into the Filter box to show only those items that have the string "sanfran" (case insensitive) somewhere in their names. We see right away there is indeed an image in the Oracle server with the desired name.

We can see information on that image by clicking it to highlight it. The status bar at the bottom of the display shows that it is a 3 channel image (as expected for an RGB image) and is 1514 x 1440 pixels in size. We can bring it into our project by clicking on the Link button in the toolbar. We then press the Close button to close the database console.
When we do so, a new linked image appears in Manifold in the project pane. In this example, we linked the image right back into the same project from which we exported the image, but we could have just as easily closed Manifold and linked this linked image into a new project or into any project. The linking process is almost instantaneous.

If we click open the image linked in from Oracle we see it is exactly the same as the image we uploaded from Manifold. There may be one thing we notice that's different once we try this example out on really big images: images linked in from Oracle are **fast**... really fast! It's like using an ECW compressed image in that the combination of fast Oracle DBMS image storage, fast access and manipulation by Manifold and fast Manifold exploitation of pyramids results in images that are much faster to open, pan and zoom than ordinary local images.

Note that this image is a **linked** image so it is coming in on the fly from the Oracle server. It is not stored in the local Manifold project. If we have a fast connection to our Oracle server we will be pleased with the performance. If we link the image through some appallingly slow Internet connection to an Oracle server sitting on the other side of the planet we might not be so happy, but in that case the problem is the slow Internet connection and not the speed of the server.

If we wanted to **import** the image from the Oracle server we could have just as easily done that in the database console by highlighting the image and then clicking the **Import** button in the console’s toolbar. That would have imported the image into a local RGB image that would be stored within the Manifold project.

**Step 3: Import a Surface from an Image Channel**

Come to think of it, we can show an example of importing a raster something from an Oracle database by showing off Manifold's ability to bring in surfaces from image channels. This is a capability that is often used when "images" stored in Oracle are really raster data sets that consist of more than one channel where each channel encodes some value such as terrain elevation, temperature or other value that is represented as a surface.

We don't have such a data set for this example, but we do have an RGB image with 3 channels (Red, Green and Blue) already exported into our server. We can import one of the three channels, making pretend it is surface data. This is a little weird, but it shows the process. [If the image was really a stored surface, it would also have a Height channel that could be imported to reconstitute the surface.]
We open up the database console one more time and connect to the Oracle server by pressing the **Refresh** button on the toolbar. We once again enter *sanfran* into the **Filter** box so that instead of showing us hundreds of items in the database the console only shows us those items with "sanfran" in their name.

As before, the console shows us the *SanFran* image we uploaded. This time we click the + box next to the image name to expand that image’s hierarchy.

We can see that there are three channels under the image. If we click one of them to highlight it we can see that the status bar at the bottom of the dialog reports that it is 8-bit unsigned Integer data.

We click the bottom channel to highlight it and then press the **Import** button in the toolbar.
A new surface and matching terrain appear in the Manifold project pane. Note that this is not a linked surface because it was imported and not linked from the Oracle server.

If we click open the surface we see a shaded relief surface created from the Blue channel of the RGB image. The surface has been interpreted from the values of the pixels, treating their color value as if that color value represented a height. Blacks are "low" terrains with all black being a height of zero while whites are "high" terrain.

We can view the terrain to see this effect. The view is roughly to the north and shows the upper two thirds of the terrain as seen when hovering over the ocean Southwest of Monterey Bay. The broad, lighter swath of higher "terrain" in the foreground is Silicon Valley, which is light grey-green in the image.

The screenshot above was created by setting the Z scale in the Terrain - Surface dialog to a value of 0.10 to minimize the rather abrupt transition between pixels. A Black to white palette was used and 64 tiles are being displayed so that the surface can be seen in its entirety when hovering above it. No clouds or water are used, although there is some fog to color the sky.

**Step 4: Uploading a Palette Image**
Suppose we start with a palette image instead of with an RGB image?

For example, suppose we create a *SanFranPalette* image like the one above, which is the *SanFran* RGB image converted into a palette image using adaptive interpolation and sixteen colors.

We can upload this image into Oracle using exactly the same procedure as in Step 1 above.

However, when we look at our server using Database Console we can see that the new image consists of only one channel and not three.

**Note**

If we have Database Administrator Edition we can use the Tools - Batch Export command to export many images or surfaces at once to Oracle.

**Technical Note: Oracle Image Name Dialog**
Normally the Export Image dialog is used without manual configuration of Oracle GeoRaster storage. Experts who are deeply familiar with the inner workings of Oracle GeoRaster storage may want to manually adjust default settings.

If we want to manually choose settings for GeoRaster storage in Oracle we can click the [...] browse button to the right of the Name box to launch the Oracle Image Name dialog.

Controls

- **Georaster table**: Name of the raster reference table.
- **Georaster column**: Name of the column in the raster reference table.
- **Raster data table**: Name of the raster definition table.
- **Raster ID**: ID of the raster in the raster definition table (an integer value).

Raster Schemas

The names of Manifold images stored in Oracle can use one of the following schemas:

- RDT
RDT is the name of the raster definition table, RASTERID is the ID of the raster in the raster definition table (an integer value), RASTERTABLE is the name of the raster reference table, and RASTERCOLUMN is the name of the column in the raster reference table.

In addition to recognizing the above schemas, the export dialog also allows editing all parts of the image name explicitly using the Georaster table, Georaster column, Raster data table and Raster ID values.

To understand what these schemas mean, let's take a look at how Oracle stores images (that is, rasters). Oracle stores images in a relatively complex, but scalable, way.

Images are made up of tiles. The tiles for each particular image are stored in a table called a Raster Definition Table or RDT for short. An RDT can contain tiles for more than one image, with each image having a unique ID called a RASTERID above.

An Oracle database can have more than one RDT. There normally is at least one more table called a Raster Reference Table or RRT for short and called RASTERTABLE above, which lists the RDTs and the images they contain.

An Oracle database can have more than one RRT. Finally, an RRT can technically have more than one set of columns referring to RDTs, called RASTERCOLUMN above.

Normally, when uploading an image to Oracle we don't care about all this stuff and will just enter the name to be used for the exported image without any dots. For example, we might use the name SanFranciscoBayArea.

When that is done Manifold will use the first schema and will use the entered name as the name of an RDT. Manifold then will then assume the default RASTERID (a value of 1) and the default RASTERTABLE (whatever is the first found RRT) and the default RASTERCOLUMN (whatever is the first applicable set of columns).

If using the default values above identifies an existing raster already in the database, after popping open a confirmation dialog Manifold will overwrite it. If the values do not identify any existing raster, Manifold creates a new raster.

Notes

This example uses Oracle GeoRasters, as found in Oracle's flagship Oracle Spatial product. However, using standard Manifold spatial DBMS facilities we can save images at very high performance using regular Oracle distributions. For examples, see the Example: Storing an Image in SQL Server 2008 and Example: Storing an Image in Manifold Spatial DBMS topics.

SQL Server Spatial DBMS Facilities

Manifold Enterprise Edition provides several ways of performing spatial DBMS work with Microsoft SQL Server:

- **Microsoft SQL Server 2008** - This new Microsoft product provides spatial support using native spatial DBMS capability such as Oracle Spatial or IBM DB2 with Spatial Extender. Manifold Enterprise Edition and higher editions have built-in capability to work with native SQL Server 2008 spatial capabilities, including both GEOMETRY and GEOGRAPHY data types. Manifold has supported SQL Server 2008 spatial capabilities since the very first SQL Server 2008 spatial pre-release in 2007. See the Example: Configuring SQL Server 2008 topic before working with SQL Server 2008.

- **Microsoft SQL Server 2005 with Manifold Spatial Extender** - Manifold has created a spatial extender for SQL Server 2005 to enable users to work with SQL Server 2005 as a high-performance spatial DBMS until SQL Server 2008 is released. The Manifold spatial extender utilizes Manifold geometry and Manifold spatial indices with a small amount of code that is uploaded into the SQL Server 2005 server for execution server-side. The uploaded code enables SQL Server 2005 to achieve better performance than a purely generic use of spatial indices. The Manifold Spatial Extender also works with SQL Server 2005; however, if we have SQL Server 2008 we should use SQL Server 2008's spatial capabilities. **Note:** When used with SQL Server Express 2005 the Manifold Spatial Extender requires SQL Server Express 2005 SP2.

- **Microsoft SQL Server with Manifold Generic Spatial Index** - This applies to SQL Server 2000 and more recent SQL Server editions such as SQL Server 2005 and SQL Server 2008. Because SQL Server, like almost every other big-name DBMS, provides binary storage we can use Manifold's generic, non-native spatial DBMS capability within SQL Server using whatever Manifold-supported geometry type we like (such as Manifold's Geometry or OGC WKB) together with Manifold-created spatial indices. This usage of SQL Server is just as we would use any other ordinary DBMS, such as MySQL, as a spatial DBMS through Manifold-managed spatial facilities. For performance reasons, with SQL Server 2005 it is always a better idea to use the Manifold Spatial Extender for SQL Server than to use generic spatial indices. Manifold generic spatial indices also work with SQL Server 2008; however, if we have SQL Server 2008 we should use SQL Server 2008's spatial capabilities.

- **Microsoft SQL Server 2005 with ESRI SDE** - ESRI products can utilize a SQL Server 2005 installation to host an ESRI SDE geodatabase. If SQL Server 2005 hosts an ESRI SDE geodatabase Manifold can connect to that ESRI SDE geodatabase and import and link drawings using ESRI conventions. It is possible for SQL Server 2005 to be used by ESRI products to host Personal geodatabases as well, in which case Manifold can also connect and work with that geodatabase like the SDE case. However, as of the present writing ESRI Personal geodatabases are usually encountered only in the form of Access .MDB files and only rarely using SQL Server, where SDE appears to predominate.

Manifold can store images and surfaces in SQL Server 2008 and SQL Server 2005 using Manifold's generic spatial DBMS capabilities. Manifold Enterprise Edition or above is required to connect using native connections to spatial DBMS such as Oracle Spatial, DB2 with IBM Spatial Extender, SQL Server 2008 spatial and PostgreSQL / PostGIS.

**Very Important:** Due to changes in SQL Server 2008 between pre-releases and final production form, it is very important that all work with SQL Server 2008 be done using a production version of SQL Server 2008 and the current version of Manifold. Do not use pre-release versions of SQL Server 2008 (so-called "CTP" versions) and do not use old versions of Manifold.

**SQL Server 2008 Geometry Types**

SQL Server 2008 spatial capabilities include support for two native geometry types: a planar GEOMETRY type similar to the geometry types used by other spatial DBMS products and a geodetic GEOGRAPHY type. The internal workings of either type have not been documented by Microsoft as of this writing, so Manifold uses these types the same way as it does SDO_GEOMETRY from Oracle Spatial.

That is, when data is brought in from SQL Server native GEOMETRY or GEOGRAPHY storage by importing or linking a drawing it is dynamically cast into Manifold Geometry type. When a Manifold drawing is exported into SQL Server, Manifold Geometry is automatically cast into SQL Server native GEOMETRY.

Any edits or other operations performed on SQL Server native GEOMETRY or GEOGRAPHY drawings that are linked into Manifold are dynamically manipulated so that whatever is done in the Manifold session is correctly updated within SQL Server native storage. Any re-projection required to show a linked SQL Server native GEOMETRY or GEOGRAPHY drawing within, say, a Manifold map in a different projection will automatically be done on the fly.
Note that Manifold can import or link a drawing from either SQL Server native GEOMETRY or GEOGRAPHY but that exports from Manifold will always be exported into SQL Server native GEOMETRY. Exports are not available into SQL Server GEOGRAPHY.

If you have a drawing that uses SQL Server GEOGRAPHY Manifold will be happy to use it. You can import it or link it into Manifold. If you link it into your Manifold project, Manifold will happily allow you to edit objects in it, to delete them, to create new objects and so forth. But Manifold will not create a new drawing for you within SQL Server that uses GEOGRAPHY. This limitation arises from the unique nature of the GEOGRAPHY type and may be relaxed in future versions. For the time being, it is not in any way a limitation for GIS operations since GIS data at the present time is universally planar in form, such as the SQL Server GEOMETRY type.

It is also possible that should Microsoft document either the GEOMETRY or GEOGRAPHY type Manifold will add these as intrinsic types that can be held in storage outside of SQL Server, much as can OGC WKB be used in the form of the Manifold Geometry(WKB) type.

**SQL Server 2008 Projections**

The GEOGRAPHY type always uses Latitude / Longitude. Importing or linking a drawing from SQL Server 2008 that uses GEOGRAPHY type will import or link the drawing into Manifold using Latitude / Longitude projection. Manifold recommends that all storage into GEOGRAPHY type adopt the convention of utilizing coordinates developed using the WGS84 datum.

When reading and writing spatial data stored on SQL Server 2008 spatial using Microsoft's GEOMETRY type, Manifold represents coordinate systems using EPSG codes. EPSG, the former European Petroleum Survey Group organization, has been absorbed into the International Association of Oil and Gas Producers (OGP), but the database of coordinate systems is still widely known as EPSG. EPSG comprises one of the largest vendor-neutral, unambiguous and expertly-developed sets of coordinate systems known. Using EPSG with SQL Server 2008 spatial GEOMETRY is a great way of eliminating the confusion one might encounter with proprietary methods of specifying coordinate systems.

Although EPSG codes cover very many coordinate systems, because Manifold can handle a much larger set of projections than those covered by EPSG, it is possible that a drawing in Manifold uses a coordinate system (projection) not available in EPSG. For example, EPSG does not have a code for Orthographic projection.

If a Manifold drawing uses a coordinate system not supported by EPSG, when the drawing is exported into SQL Server 2008 GEOMETRY, Manifold will re-project it on the fly into Latitude / Longitude form (using EPSG code 4326). Built-in Manifold coordinate systems include all EPSG coordinate systems so that drawings imported or linked from SQL Server 2008 GEOGRAPHY need never be re-projected for use in Manifold.

SQL Server 2008 spatial allows third parties to choose some other coding method to represent coordinate systems instead of EPSG. If some third party application has used some other coding scheme then Manifold will not be able to automatically detect the correct coordinate system in use, and the correct coordinate system will have to be specified using the Edit - Assign Projection dialog after the drawing is imported or linked into Manifold.

**Re-projection in SQL Server 2008**

Note that although Manifold will happily re-project data as necessary and can even re-project on the fly so that drawings stored within SQL Server 2008 using different projections can be used together for spatial analytics such as topology overlays, as of the present writing SQL Server 2008 does not have server-side re-projection capability. This means that the usual Manifold facilities for changing projections of drawings stored in spatial DBMS won't work if native SQL Server 2008 spatial enhancements are used. We can, however, still use Administrator Console (available in Database Administrator edition or Ultimate edition) to examine the projections in use.
Launching the administrator console we can connect to SQL Server 2008 using the data source that is configured in the example topics below.

We press the Columns button in the console’s toolbar to turn on the Projection column if it is not already visible. This reports the projection in use by drawings. We choose a drawing, a version of the standard Mexico example, that has been uploaded to SQL Server 2008 spatial storage using an unusual projection, MTM Zone 3. We double-click into the projection cell for that drawing.

The Projection dialog used with EPSG codes reports the details of the projection in use. We can scroll down to EPSG 4326 and click on it to highlight it. We can try to re-project by pressing the OK button.
However, we cannot modify the projection (coordinate system) in place.

If we want to re-project the drawing this is easy to do in Manifold: import the drawing into Manifold, re-project it within Manifold, and then export it back into SQL Server 2008.

**The Manifold Spatial Extender**

The Manifold Spatial Extender for SQL Server is a free extension module for SQL Server which provides spatial index functionality for Manifold System. The Manifold spatial extender works with all versions of SQL Server starting with SQL Server 2005. Always make a point of installing the Manifold spatial extender on the server machine whenever using SQL Server 2005 as a spatial DBMS.

Although the Manifold spatial extender works fine with SQL Server 2008 as well, normally we would use native SQL Server 2008 spatial capabilities instead of installing the Manifold spatial extender and using generic Manifold spatial capabilities.

See the Manifold Spatial Extender for SQL Server topic for details.

**Technical Note on Pre-Release GEOGRAPHY Type Coordinate Ordering**

This note applies only to users who experimented with pre-release versions of SQL Server 2008 or who are still using an older Manifold release with SQL Server 2008. If you are using a production version of SQL Server 2008 with a current Manifold release this note does not apply to you.

Experimenting with pre-release software always involves the risk that something important will change in the production version. Users who experimented with pre-release versions of SQL Server 2008 should take note of a very important change made by Microsoft in the final production version of SQL Server 2008.

During Microsoft's development of SQL Server 2008 several pre-releases, called CTP (Community Technology Preview) releases were issued during 2007 and 2008. Up until the final CTP and final release to manufacturing in 2008, SQL Server 2008 GEOGRAPHY type was unique in that it used (latitude, longitude) coordinate ordering, that is (Y, X), ordering instead of the (X, Y), (longitude, latitude) ordering that is universally used by all other spatial DBMS and GIS products and essentially all other vector and raster GIS formats, including SQL Server's own GEOMETRY type when storing Latitude / Longitude data.

Based upon feedback from beta testers and the development community, the final CTP and final production release of SQL Server 2008 changed the ordering of coordinates in GEOGRAPHY type to the industry standard, that is (X, Y), (longitude, latitude) ordering. Every application designed around pre-release versions of SQL Server 2008, including Manifold, therefore had to change accordingly.

Because Manifold supported GEOGRAPHY type since the very first spatially-capable CTP in 2007, all Manifold Release 8 builds published before the final release of SQL Server 2008 took into account the backwards ordering of coordinates in SQL Server 2008 pre-releases. When importing or linking GEOGRAPHY, all Manifold builds published up through and including July, 2008, would automatically swap coordinate ordering into the (X, Y) order expected by all other systems, including Manifold. The last Manifold build that automatically swapped coordinate ordering was 8.0.8.

All Manifold releases from August, 2008 onward were changed to follow SQL Server's adoption of industry standard ordering so that they do not swap coordinate order for GEOGRAPHY type. If you are reading this Help topic from within your Manifold installation you are operating a newer Manifold release which does not swap coordinate order in SQL Server 2008 GEOMETRY type.
Developers who were working with pre-release SQL Server 2008 versions should be aware that SQL Server 2008 GEOGRAPHY coordinate order has changed from backwards ordering in the earlier CTPs to industry standard ordering in production SQL Server 2008 and that Manifold has also changed accordingly. Developers should be aware that using a newer Manifold release with older data stored in a pre-release SQL Server 2008 database will result in backwards coordinate ordering, since the old SQL Server system was backwards but current Manifold releases no longer automatically flip the backwards ordering. Likewise, using a Manifold release issued on or before July, 2008, with the production version of SQL Server 2008 will also result in backwards coordinate interpretation, because the older Manifold release will think that the SQL Server coordinates are backwards and will swap them automatically.

The solution to avoiding all problems is very simple: use the latest Manifold release with production SQL Server 2008. Do not use pre-release SQL Server 2008 versions and do not use older Manifold releases with production SQL Server 2008.

**SQL Server 2008 Examples**

SQL Server 2008 has been used in a series of example topics illustrating work with this fine new Microsoft spatial DBMS product.

Example: Configuring SQL Server 2008
Example: Linking a Drawing from SQL Server 2008
Example: Storing a Drawing in Manifold Spatial DBMS
Example: Storing a Drawing in SQL Server 2008
Example: Tracing Virtual Earth into SQL Server 2008
Example: Storing an Image in SQL Server 2008

**SQL Server 2005 Examples**

SQL Server 2005 Express has been used in a series of example topics illustrating use of generic Manifold spatial DBMS capabilities. Many of the techniques illustrated (such as use of the Administrator Console) also apply to SQL Server 2008.

Example: Storing a Drawing in Manifold Spatial DBMS
Example: Storing an Image in Manifold Spatial DBMS
Example: Storing a Surface in Manifold Spatial DBMS

Example: Configuring SQL Server 2008

The example assumes SQL Server 2008 has been installed on a machine called GL and we are working on that same machine. The default installation from SERVERS/SPLASH.HTA was used. (Screenshots were made using pre-production SQL Server 2008 software. They may be slightly different from production versions of SQL Server.)

This example shows how to configure Manifold data sources for a SQL Server 2008 installation using the Data Source dialog. It also shows how to use the Database Console to configure SQL Server 2008 for use by an explicit user and password instead of Windows integrated security.

Sometimes when working with SQL Server it is easiest to use explicit user / password pairs instead of integrated security. The classic example is using SQL Server 2008 spatial data within a Manifold Internet Map Server project, where it might be a hassle to use Windows integrated security to assure access for the IUSR_xxx account. This example shows how to set up SQL Server 2008 while providing, in passing, a detailed, step-by-step example of how various Manifold dialogs, like the Data Source dialog and the Database Console dialog, are used.

We begin by launching SQL Server Management Studio from the Windows taskbar Start button.

Using (local) for the Server name means we are working on the same machine. Press Connect.

1. Launch SQL Server Management Studio.
2. Connect to SQL Server using (local) as the Server name.
3. Press Connect.
We right-click on the server node in the Object Explorer window and choose **Properties**.

![Server Properties - GL](image)

We click on the **Security** page (in the left hand pane) and choose **SQL Server and Windows Authentication** and then click **OK**.

![Microsoft SQL Server Management Studio](image)

Back in the Object Explorer pane we again right-click the server node and choose **Restart**. We wait until the system starts and restarts the service and then we can close the SQL Server Management Studio application.

We now launch Manifold.

![Project1 - Manifold System](image)
From the main Manifold menu we choose Tools - Database Console to launch the Database Console. The Database Console allows us to browse databases and to import and link data from those databases. The lower pane of the Database Console allows us to execute queries within the database server. Now would be a good time to review the Tools - Database Console topic.

This is the first time we have used this Manifold installation, so no data sources have yet been configured. We click the [...] browse button to open the Data Sources dialog.

Now would be a good time to read the Data Source Dialog topic, as this dialog is the friend of every DBMS user. It remembers previously used data sources that we have configured, so we can easily connect to data sources with a simple point and click. It takes a moment or two to add a new data source to the dialog, but once the data source is in there we save a lot of time afterwards.
The dialog opens up with no data sources configured, since this is the first time we have used this Manifold installation and no data sources have yet been configured. We press the Add Data Source button.

That opens a typical Windows file open dialog. We choose SQL Server Data Sources as the type. Using this type means to use the native connection to SQL Server 2008 spatial DBMS.

We first will configure a data source using Windows integrated security, since we will use our status as Administrator (yes, that's how we logged in...) to configure a user, password and database within SQL Server 2008. We can then later configure a data source to use that user / password pair. Press OK.

Back in the Data Source dialog we have a new data source added to the list. We will rename it to something that later will remind us what this source is all about. We will use SQL Server - Windows Integrated Security. Press OK.
That takes us back to the Database Console, which shows the currently empty status of the server. We will now execute a series of statements in the lower query pane to configure the DBMS.

Enter the statement

```sql
create database TESTDB
```

in the lower pane and press the Run button. This executes the statement. Follow that by executing each of the following statements, pressing the Run button after each in turn:
Enter the statement

create login TEST with password='TESTPWD'

in the lower pane and press the Run button. This executes the statement.

Enter the statement

create user TEST for login TEST
use TESTDB
create user TEST for login TEST

in the lower pane and press the Run button. This executes the statement.

Enter the statement

use TESTDB
grant control to TEST

in the lower pane and press the Run button. This executes the statement.

We could, of course, if desired substitute our preferred user name, password and database name for the uppercase words in the above statements. The statements configure our SQL Server 2008 server to allow use of a user and password pair. The above statements have been broken into simpler chunks to illustration what is being done and to help avoid typos. An experienced user would execute them all together entered into the lower pane.
After executing the last statement above the Database Console will remember it in case we want to use it again or edit it. If that is not desired it is a good idea to delete the statement text so that future Database Console sessions won’t have it appear in the lower pane.

We can now configure a new data source in Manifold that connects to the server as user TEST with password TESTPWD and using TESTDB as a database. To configure and use a new data source we again press the browse button.

Once more we press the Add Data Source button.
We now choose **Use specific user name and password** and provide the name, password and database name to use. Press **OK**.

A new data source appears in the list. We rename it **SQL Server - TEST user / password** to remind us what this is about. We double-click the data source to connect using it.
Database Console is now connected using the new data source. (We've deleted the last statement issued from the query pane at the bottom.)

In subsequent examples, we will use the new data source to export data into SQL Server 2008, beginning with the Example: Storing a Drawing in SQL Server 2008 topic.

Spatial DBMS Facilities
SQL Server Spatial DBMS Facilities
Tools - Database Console
Example: Storing a Drawing in SQL Server 2008

This topic shows a simple example of exporting a drawing into SQL Server 2008. It uses the data source created in the Example: Configuring SQL Server 2008 topic.

Launch Manifold and open the Mexico drawing used in numerous examples in the Examples chapter.

To export the drawing we choose File - Export - Drawing and in the type box choose Data Sources ().
In the resulting Data Source dialog we click the user / password pair data source set up in the prior example. This connects to the server using a specified user name and password and desired database. Press OK (or simply double-click the data source).
In the resulting Export Drawing dialog we use defaults, checking to make sure the Type is SQL Server so that we use native SQL Server 2008 spatial storage. By default, all fields (columns) will be exported except intrinsic fields. The drawing will be uploaded into the DBMS using standard Manifold geometry types and a spatial index will be created. Press OK. Done!

Important: When exporting a drawing to a spatial DBMS it is best if the drawing does not contain a column called OID. This name is used by Manifold as the default name for the object identity field. If we like, we can still export a drawing that contains such a column but then we will have to remember in the export dialog to change the name of the identity field to something else.

While that is certainly easy enough to do, it is also easy to forget to do in which case the export will fail and we will wonder why. Also, it is useful to always assume that an OID field is the identity field. Therefore, it is strongly recommended to treat this field name as a reserved name.

We've now saved the drawing into SQL Server 2008 spatial storage. If we want to use the drawing, we can import it from the server or link to it using the Tools - Database Console dialog as shown in topics such as the following Example: Linking a Drawing from SQL Server 2008 topic.

Example: Linking a Drawing from SQL Server 2008

This example shows how to link a drawing stored in SQL Server 2008, using the example drawing stored in the Example: Storing a Drawing in SQL Server 2008 topic. In addition, it shows how the drawing can be used with transform operators, dynamically working with “live” data that is stored within SQL Server 2008 geometry. This example assumes data sources have already been configured as set forth in the Example: Configuring SQL Server 2008 topic.

Recall that we started with the example Mexico drawing seen above, and exported it into SQL Server 2008 spatial storage.

Launch a new Manifold session and launch the Database Console. The Database Console remembers the last-used data source for our convenience, so all we need do is press the Refresh button to refresh the connection to the DBMS server.
The Database Console shows the uploaded drawing with a drawing icon. It also shows the database table that contains the drawing as a table, in case we just want to import or link a table. If we want a more elegant presentation for novice users we can use Administrator Console to assign friendly names.

To link the drawing we click on it to highlight it and then press the Link button.

The Import / Link Options dialog opens to give us the option of linking the entire drawing or just a portion of it. The ability to link only those objects within a given area of interest allows us to use the power of SQL Server to store virtually limitless drawings while only working with a manageable portion of them within a given area.

The Version choice specifies what field to use within the drawing to reconcile multi-user edits. Since more than one Manifold user on more than one different machine could simultaneously link and edit this drawing, Manifold provides a way to resolve editing conflicts using a Version column. See the Multi-User Editing of Linked Drawings topic for details and an example.

We choose the Version column and press the OK button.
A new drawing appears in the project pane together with the drawing’s table. A database cylinder appears in the drawing and the table icons to indicate this component is linked from an external source.

If we open the drawing we see that it is, indeed, the example Mexico drawing exported into SQL Server 2008 spatial storage.
If we open the drawing’s table we see that all the attribute data for each drawing object (the various provinces of Mexico) have been stored with the drawing.

Like any linked table the data is immediately available for use within Manifold, just as if it was a local component stored within the project. For example, we can work with the data in the drawing’s table.

We can click on a column head to sort the column by ascending order, right-click on the column head for a variety of choices or simply use a shift-click on a column head to sort by descending order. In the illustration above we have shift-clicked on the column head giving population for each province to sort the table from the most populous province to the least populous.

We can make selections in the table as well. Let’s first change the selection mode to Select Add. See the Selection topic for an introduction to selection modes.
We can now click on the row handle to the left of each record to select that record. In the illustration above we have selected a few records in the drawing's table based on population values that have caught our eye.

As we select records in the table the corresponding objects will also light up in red selection color in the drawing window. Manifold provides select-back, whereby a selection made in any open window will be seen in corresponding objects in any other open window. We can select an object in the drawing and see its record selected in the table as well or vice versa.

With the focus on the drawing window, let's do something dramatic and press the Delete key to delete the selected objects.
Manifold helpfully asks us to confirm deletion. We press Yes.

Adios, provinces! Those objects have now been deleted from the drawing. Note that since this is a linked drawing that shows live, dynamic data directly from SQL Server 2008 spatial storage, we have truly deleted the objects from the SQL Server storage. If anyone else was working with the same drawing in a different connection to the same database, they would also see those objects disappear.

Since we would like to keep this particular example drawing whole for the rest of this example, we will use everyone’s favorite Manifold feature: undo. We click on Edit - Undo to undo the last action. Manifold provides single-step undo, an extremely useful feature at times.
Like magic, the deleted objects are restored. Note that the objects are shown in selection color. If we still have the drawing's table open in a different window we would see the associated records re-appear.

Let's shift gears a bit and do something with the linked drawing that shows how geometry from SQL Server 2008 can be used to do analytics.

With the focus on the drawing window we choose Edit - Select None to clear the selection.

In the Transform Toolbar we choose [All Objects] and the Centroids (Weight) transform and press Apply.
This transform operator creates a point object at the centroid by weight, that is, at what would be the balance point if the area were cut out of stiff paper, and selects the centroid points.

Note that since this is a linked drawing that is working with a live, dynamic connection to the drawing stored within SQL Server 2008, we have actually created new point objects within the SQL Server 2008 spatial storage.

[Although we don't use this characteristic, when Manifold creates a centroid for each area object, those centroid points each inherit the data attributes of the originating area. We can control how that inheritance occurs by using Transfer Rules.]

We don't want to clutter our drawing with point centroids, so we will choose Edit - Cut to cut them out of the drawing (we could also use the standard Windows CTRL-X shortcut).

We then right-click into the project pane and choose Paste.
Manifold® System Release 8.00 User Manual

Manifold cuts the centroid point objects out of the linked drawing, removing them from SQL Server 2008 spatial storage, and places them in a new drawing created in the project pane. This new drawing is a local drawing, stored within the Manifold project file. As such it is shown using a drawing icon and a table icon that do not have a database cylinder in the icons.

We right click on the new drawing and choose **Rename** and change the name to **Centroids** to make it easy to recognize what is in that drawing. Manifold by default will helpfully rename the drawing’s table for us as well.
If we open the new Centroids drawing we can see that it contains the centroid points that were cut out of the Mexico drawing. The Centroids drawing uses the same projection as the Mexico drawing, basing that upon the projection used by the objects that were cut and pasted to create the new drawing.

Let's change the projection of the Centroids drawing. This is not an example about projections, so we will go quickly.

We first use the Edit - Assign Projection dialog to verify that the Centroids drawing is indeed intended to be in Latitude / Longitude. We next launch the Edit - Change Projection dialog to change the projection.
In the Edit - Change Projection dialog we drill down and choose Orthographic as our desired projection. This is the classic "view from space" projection and has the advantage of using meters as a unit of measure, so it is very convenient for measurement calculations.

We press the Suggest button to get Manifold to suggest some reasonable values for the central latitude and longitude and then we press OK.
There is not much visible difference between the original projection in Latitude / Longitude projection and the new display using Orthographic.

Let's now use the transform toolbar again to create buffer zones.

With the focus on the Centroids drawing we use the Buffers transform to create buffers about each object that use a radius of 200,000 meters (200 kilometers). Press Apply.
Manifold creates circular buffer areas around each point, with each buffer area inheriting the data attributes from the centroid point from which it was created. Each newly-created buffer area is also selected, making it convenient to further use the areas in subsequent operations.

We will **CTRL-X** to cut the buffer areas and then **Paste** them into the project pane as a new drawing, renaming the new drawing to **Buffers** to remind ourselves what that drawing contains.

Opening the new **Buffers** drawing we see that it does indeed contain the circular buffer areas we created from the centroids.

We now choose **Create - Map** from the project pane toolbar to create a map using the **Buffers** drawing as the first layer. We first create the map using the **Buffers** drawing because we want the new map to use the same
projection. Orthographic as the Buffers drawing (which is in Orthographic because the buffer areas that were cut from the Centroids drawing and pasted to create the Buffers drawing were in Orthographic). Press OK.

We open the new map and we drag and drop the Mexico drawing from the project pane into the map. This adds the Mexico drawing to the map as a layer. We drag the Buffers layer tab to the left of the Mexico tab so that the Buffers layer appears above the Mexico layer.

Even though the Mexico drawing is in Latitude / Longitude projection it is re-projected on the fly to use the Orthographic projection used by the map. Re-projection on the fly can take some computational time in the case of large, complex drawings, so it is wise when showing layers in a map to use the projection of the largest, most complex layer for the map’s projection as well. These are such small components that rendering will be fast in all cases.
Too much opacity in the **Buffers** layer does not an elegant presentation make, so we will right click on the **Buffers** layer tab, choose **Opacity** and set the opacity to about 50 percent. That allows more of the **Mexico** layer underneath to show through to provide better visual context. Manifold has endless such visual capabilities. Although this is mainly a database storage example, it is still useful to employ such capabilities for a better visual presentation.

We next will do a slightly more sophisticated operation that is not shown in step-by-step detail: we will dissolve all of the different buffer areas into a single area object.

We do this by opening the **Buffers** drawing's table, selecting all records, changing the value in one of the fields (such as the **Auto** field) to 1, which is a shortcut way of changing that value for that column for all of the records.
We then click on the map to move the focus back to the drawing layer and choose **Drawing - Dissolve**, dissolving on the **Auto** field. Manifold will dissolve all of the records with the same value in that field into the same object, in this case making one object out of all the buffer areas.

Note that the resulting object, as seen above is a single, branched object. That is, even though it appears to be at least two separate areas both of those apparently separate areas are part of the same complex, branched single area object. Manifold can automatically handle branched objects such as areas that contain holes or are single objects with multiple islands.

The above is a lot of preparation just to get a layer that we will now use to "cookie-cut" our **Mexico** drawing.

In the transform toolbar, we use the Clip with (Intersect) transform to clip all objects in the **Mexico** drawing with all objects in the **Buffers** drawing. Press **Apply**.

Manifold uses the buffer area to cut all of the area objects in the **Mexico** drawing, deleting any portions of area objects in the **Mexico** drawing that do not fall within a buffer zone. This is a very common operation in GIS.

For example, suppose the buffer area represents the coverage radius from radio antennas, as in a cell phone application. If we had an antenna at the centroid of each province in Mexico and the range was 200 kilometers from each antenna, the buffer zone shows us the coverage attainable. The clip transform shows the land area that is reachable from all antennas.

Note that even though the objects in the **Mexico** drawing are in a different projection from the **Buffers** drawing the operation still works. Manifold will automatically re-project on the fly as necessary when doing spatial analytics.

Note also that even though the objects in the **Mexico** drawing are dynamically linked into Manifold from SQL Server 2008 spatial storage the transform still works. The objects are automatically edited in place within SQL Server by the transform.
We can open the **Mexico** drawing in its own window to see the drawing on its own, seen in the **Latitude / Longitude** projection used by this drawing.

We choose **Edit - Select None** to deselect all objects to get a clear view of the objects as edited.
We can select just one of the objects to see the intricate shape automatically created when the complex buffer zone object was used to slice through the also complex shapes of Mexican provinces.

Note from this view that what appears to be a circle when viewed from space or when computed on the basis of radius in a projection that preserves linear measurements, like Orthographic, does not appear as a circle given the distortions of a cylindrical presentation like Latitude / Longitude. The cuts in the Northwest part of Mexico appear slightly ellipsoidal when viewed in Latitude / Longitude: attempting to "draw a circle" in a Latitude / Longitude view will not generally result in a true circle upon the Earth's surface.

Example: Tracing Virtual Earth into SQL Server 2008

This topic continues the series of SQL Server 2008 examples set forth in the SQL Server Spatial DBMS Facilities topic. We use data from Microsoft Virtual Earth to create a drawing within SQL Server 2008 showing buildings in the Microsoft Redmond campus and then we edit that drawing to show how drawings linked from SQL Server 2008 into Manifold maintain their dynamic links back to SQL Server spatial storage. This example assumes data sources have already been configured as set forth in the Example: Configuring SQL Server 2008 topic.

We begin this example by opening the US Base Map.map project from the Exporting KML to Google Earth tutorial topic. That project has two handy linked images, one from Microsoft Virtual Earth satellite imagery and the other from Microsoft Virtual Earth road map imagery, and also has a useful map of the US as boundaries. We are mainly interested in the Virtual Earth layers. This example assumes, of course, that we are connected to the web so that Manifold facilities such as image server module interfaces, will operate correctly.

We delete all the components from that project we don't need and we save it under a different name. This will be our new project for creating a drawing that shows buildings in the Microsoft Redmond campus.

We begin with a project that has two linked images and a drawing. We won't use the USA drawing but it is there in the project should we need it. We create a map from the Virtual Earth Satellite Image and we open the map.

Wow! As always, the sheer breadth and quality of Virtual Earth imagery never fails to impress. This particular image was linked using the extents of the entire US plus parts of Mexico and Canada. The amazing thing about the image before us is that we can zoom into any part of it and Manifold will arrange to stream in more detailed image tiles to the limit of resolution supported by the host image server. Considering that the host image server is Microsoft Virtual Earth that ultimate detail is impressive indeed. We can zoom into this image to see virtually any part of the US in astonishing detail.
Our objective is to zoom into that part of Redmond hosting the main Microsoft campus, but it is not so easy to see where Redmond is from a satellite view.

To provide better orientation, we will drag the Microsoft Virtual Earth street map image into the map and then use the Zoom Box tool to zoom into the Seattle area.
Note that the magic of Manifold image server technology connected to Virtual Earth automatically fetches more detailed views. Knowing that Redmond is somewhere near Bellevue we will zoom again into the Seattle area near Bellevue.
There's Redmond... let's zoom closer.
At this point we know we are looking at Redmond, but we are darned if we know where exactly Microsoft is in this display. To get a fix on the Microsoft campus, we will use Manifold's built-in geocoding capability (available if we have the Geocoding Tools extension installed or any edition from Universal edition on up).

We choose **Edit - Go To**, choose **Address** in the **Go To** box and give the published address of Microsoft Corporation. Press **OK**.

That's better. Let's zoom further into the Microsoft campus.
At this point we have zoomed far enough into the Virtual Earth street image that we can see individual Microsoft buildings. Time to switch to the satellite image.
We do this by double-clicking on the Virtual Earth Street Map Image layer to turn it off, and clicking on the Virtual Earth Satellite Image layer to make it the active layer. We zoom further into the image.
That's a good view of much of the main Microsoft campus in Redmond. Let's zoom even further into the image, to the point that an individual Microsoft building fills the screen.
Very good. Now we will switch gears a bit and create a drawing into which we can draw areas that trace over the shapes of individual buildings.

To do so, we right click onto the Virtual Earth Satellite Image tab and choose Add - New Drawing from the context menu.

The Create Drawing dialog allows us to name the new drawing and to provide any descriptive notes we would like. We enter the name Buildings and press OK.
A new tab appears in the map for the new drawing.

In the project pane, we see that a new drawing, called **Buildings**, has been created, together with the drawing’s table.
If we open the drawing's table we see that it is empty and consists of just one column, the built-in ID column that stores the object ID for any objects added to the drawing. We will add another column. To do so, we right-click on the column head.

From the context menu we choose Add - Column.

In the Add Column dialog we provide a name for the new column (we will call it Buildings) and for the type of the column we choose Text (ANSI, variable-length) from the seemingly endless list of different database types offered by Manifold in the Type box pull-down menu. Press OK.

Very good. We now have a new column in the drawing's table. So far there is nothing in the table because we have not added any objects to the drawing.

One more thing: because this is an example and we want to show off a bit, we will change the new drawing's projection. When a new drawing is created in a map it inherits the projection of the map, in this case the same Mercator projection used by the Virtual Earth layers from which the map was created.
Changing the projection of the Buildings drawing is easy. First, we right click on the Buildings drawing in the project pane and choose Assign Projection to verify that the starting projection is what we intend it to be. This is a "belt and suspenders" safety check by Manifold applied to all components the first time they are used in a projections context.

Next, we right click on the Buildings drawing in the project pane and choose Change Projection to get the dialog shown above. In that dialog we choose Latitude / Longitude projection and press OK. That changes the projection of the drawing to Latitude / Longitude projection.

When the projection of a layer in a map is changed the map will re-sync itself as it re-projects the component on the fly to display it in the projection used by the map. We click the Back button to get back to the same zoom and pan used earlier.

There is one more housekeeping thing we will do before launching into a wonderful and productive editing session. We will turn on Instant Data mode.
To do this, we choose **Edit - Instant Data**. This sets a highly useful editing mode so that whenever we draw a new object into a drawing Manifold will automatically pop open an editing dialog to enable us to add field values for that object. This is one of those deals that sounds like a totally nerd-alert, dry feature but in actual practice is one of those things you cannot live without once you taste it.

With the focus on the **Buildings** drawing layer in our map, we click the Insert Area command to use that tool.

To use this tool we click on the outlines of the area desired. In this case we click along the edges of the building over which we want to create an area. This is a good example of tracing, whereby we create new map objects by tracing in a drawing layer above an image layer.

When we are finished drawing the area we **right click** to indicate we are done.
A new area appears in the drawing and because we have Instant Data mode on a dialog pops open to enable us to enter attribute data for that object. We enter 21 into the Buildings field because we know this is building 21 in the Microsoft campus. Press OK.
A new area object is created in the drawing.

If we open the drawing's table we see that a new record has been created for that drawing object, with the value of **21** for the **Buildings** field.

Let's pan over to a nearby building and trace over it to create another area object.
When we are done the Instant Data mode automatically pops open the dialog with the cursor pre-positioned in the last field edited with the last-used data entered, ready for us to modify it or enter new data.

Instant Data makes it extremely efficient to enter large numbers of new objects together with data attribute information for each new object. It is the first choice for data entry when recording assets or other repetitive information. For example, a crew can use it together with Manifold's GPS Console capability to record the location of thousands of assets, such as fire hydrants or electrical transformers or even 911 addressing in a day.

We enter **35** for this building and press **OK**.
In the drawing’s table we see that we now have two records for the two objects in the drawing.

Zooming out a bit in the map we see there are now two area objects drawn into the Buildings drawing.

Let’s switch gears and export the Buildings drawing into SQL Server 2008 spatial storage. We can’t export a drawing into SQL Server unless it contains some objects. We have created two objects in this drawing so we can now export it into SQL Server. After export, we will link the drawing back into our Manifold project and continue editing it “in place” within SQL Server.

To export the drawing, we right click onto the Buildings drawing in the project pane and choose Export.
In the resulting dialog we choose **Data Sources** () as the type to which this drawing will be exported.

That launches Manifold’s Data Source dialog, which helpfully remembers data sources that have been previously configured. We have two data sources, configured in the Example: Configuring SQL Server 2008 topic. We choose the data source using an explicit user login and password since that connects to the database used in previous examples.
In the resulting **Export Drawing** dialog we verify that the **Type** is **SQL Server** and otherwise accept defaults. Press **OK**.

The drawing is now exported into SQL Server 2008 spatial storage. For the rest of this example we will use the drawing resident within SQL Server.

To do that, we will first right click on the **Buildings** drawing in the project pane and delete it from our project. This also deletes it as a layer from the map. Next, we will link the drawing back in from the database. We will do so by launching Tools - Database Console.
The database console helpfully remembers the last-used data source. We press the Refresh button to refresh the connection.

After refresh, the database console lights up with a listing of all the components in this database. As we can see, there are plenty. For now, we have not used Administrator Console to assign friendly names so they are displayed in their native SQL Server object names. Manifold will helpfully put a drawing icon next to those database objects that it knows contain drawing geometry.

We click on the database object that is obviously our Buildings drawing uploaded in the prior step and we press the Link button to link it into our project.
The link options dialog allows us to choose to use all objects or just some area of interest subset. We use all objects since there is hardly anything to this drawing. If we wanted to grab just a manageable subset of some terabyte-sized drawing stored in SQL Server we would no doubt use some area of interest subset.

Manifold creates a version column by default to support multiuser editing of linked drawings. We make it a habit of using that column just in case someone else connected to the DBMS also wants to simultaneously edit the same drawing. Press OK.

A new drawing appears in the project pane. The drawing’s icon incorporates a database cylinder graphic to indicate this is a drawing linked into the project from an external data source.

If we open the drawing we see that it contains two area objects. They look a bit strange because the drawing uses Latitude / Longitude as its native projection, and that projection shows considerable distortion in higher latitudes like those where Redmond is located.
If we open the drawing's table we see that it does indeed contain all the data attributes uploaded into SQL Server.

However, our task is not to look at the drawing on its own but to work with it in a layer above the Virtual Earth imagery we were using earlier. We therefore drag and drop the linked drawing from the project pane into the map. It appears as a layer, re-projected on the fly into the Mercator projection used by Virtual Earth and the map. Note that the objects overlay perfectly, as we would expect them to do.
The gray default formatting of new objects is getting boring, so we will format the area background color for the Buildings layer to be bright yellow.
The interesting thing about the Buildings drawing layer is that it is a "real time" connection to the drawing stored within SQL Server. If we edit the drawing, we are dynamically changing the data in SQL Server. Although the layer seems local, it is a visual means of editing the contents of our database with none of the hassles of manually specifying coordinates or command-line interaction.

For example, we can zoom into a different building and create another area traced over it.

When we finish the object, because Instant Data mode is still on a dialog pops open to enable us to enter data for this object as well. We enter building 34.
Zooming out, we see that we now have three buildings in this drawing.

If we click open the drawing’s table (also linked in automatically from SQL Server storage), we see that we have data for three objects in the table.

What is also interesting about the drawing’s table is that it too is an interface that we can use to manage data within SQL Server. For example, suppose we want to add a new column to the table?

That is easy to do by right clicking on the column head and choosing Add - Column from the context menu
In the **Add Column** dialog we provide a name for the new column (we will call it **Cafeteria**) and for the type of the column we choose **Text (Unicode, variable-length)** just to show that Manifold can handle Unicode text as well as ANSI text. Press **OK**.

<table>
<thead>
<tr>
<th>ID</th>
<th>DID</th>
<th>Buildings</th>
<th>Cafeteria</th>
</tr>
</thead>
<tbody>
<tr>
<td>108</td>
<td>1</td>
<td>21</td>
<td></td>
</tr>
<tr>
<td>109</td>
<td>2</td>
<td>35</td>
<td></td>
</tr>
<tr>
<td>110</td>
<td>3</td>
<td>34</td>
<td></td>
</tr>
</tbody>
</table>

A new column appears in the table. We have actually added a new column within the table structure in the SQL Server 2008 database as well. Manifold has extraordinary capabilities for managing tables within databases, better than most DBMS products do.

Let's trace one more building. Back in the map window we use the **Insert Area** tool to create an area for another building.
When we finish the new area the instant data dialog automatically pops open as before, but this time it shows the new Cafeteria field as well. The cursor is helpfully positioned within the last field used, ready to go.

We enter 36 for the building and Y for the cafeteria field, intending to indicate this building has a cafeteria. Press **OK**.
The new area appears in the drawing. It uses the formatting we have specified for that drawing.

<table>
<thead>
<tr>
<th>ID</th>
<th>DID</th>
<th>Buildings</th>
<th>Cafeteria</th>
</tr>
</thead>
<tbody>
<tr>
<td>108</td>
<td>1</td>
<td>21</td>
<td></td>
</tr>
<tr>
<td>109</td>
<td>2</td>
<td>35</td>
<td></td>
</tr>
<tr>
<td>110</td>
<td>3</td>
<td>34</td>
<td></td>
</tr>
<tr>
<td>111</td>
<td>4</td>
<td>36</td>
<td>Y</td>
</tr>
</tbody>
</table>

If we open the drawing's table we see that a record for the new object, complete with attributes as we've entered them, has appeared.
Zooming out, we can see we now have four new area objects in this drawing. The last two have been added using the linked drawing from SQL Server. The edits we’ve made in this interactive Manifold session have applied in real time to the data set stored in SQL Server.
All Manifold capabilities (thousands of them) apply to the use of such linked drawings from SQL Server 2008. For example, in the illustration above we've created a labels layer that prints the Microsoft building number above each building.

We have also used thematic formatting to color the buildings automatically by whether they have a cafeteria or not. Green indicates a cafeteria. Thematic formatting and labels took, literally, less than a minute to do.

Many, many other Manifold facilities are open to us: we can create a web site in seconds that provides dynamic access to the SQL Server data, or we could publish the contents as a PDF. Although this topic uses many illustrations, it can be done by a semi-experienced Manifold user much faster than the time required to read through it. An experienced person could create this project in just a few minutes.

What is remarkable is that bringing together technologies like Virtual Earth and SQL Server and Manifold together makes it extremely easy to do what used to be very difficult and error-prone.
Consider, for example, the illustration above from the Microsoft web site which shows inaccurately the position and orientation of Building 36. In just a few short minutes we have created a more accurate rendition. Although we did not take great care to draw areas accurately, Manifold has many facilities (such as scrolling in dynamically while creating a new object) that make it fast and easy to draw accurately.

Example: Storing an Image in SQL Server 2008

This topic continues the series of SQL Server 2008 examples set forth in the SQL Server Spatial DBMS Facilities topic. In this example we store a large image in SQL Server 2008 using Manifold spatial facilities. We then link it into a project to show the outstanding speed and performance obtained when even large images are stored in SQL Server 2008. This example assumes data sources have already been configured as set forth in the Example: Configuring SQL Server 2008 topic.

SQL Server 2008 spatial enhancements do not include a raster image type analogous to Oracle GeoRasters as provided within Oracle’s flagship Oracle Spatial product. However, SQL Server 2008 does a masterful job of storing binary data and when that binary data is organized as geospatial image data using Manifold spatial DBMS capabilities, the result is that we can store very large images within SQL Server 2008, preserving full projection information, and utilize them as if SQL Server 2008 had its own native geospatial image storage type.

This example uses SQL Server 2008; however, because standard Manifold spatial DBMS capabilities are used it could be done using almost any DBMS, such as SQL Server 2005, ordinary Oracle distributions, PostgreSQL/PostGIS or MySQL. It does not require use of the Manifold spatial extender, as the native facilities of SQL Server are used to manage the binary data stored by Manifold.

We will begin with an approximately 600 MB image that shows the Montara Mountain region of California. In the upper right is San Francisco International Airport on San Francisco Bay. At the lower left is the fishing port at Half Moon Bay on the Pacific Ocean. The long, diagonal lake and valley running from the center top to the center right just below and to the left of the settled area near the airport is the valley of the San Andreas fault, the rupture of which in 1906 leveled San Francisco by earthquake and fire.

This is an ordinary RGBA image kept within a Manifold project. It was created by opening the sample Montara Mountain surface used in many example topics, linking in an image from a Microsoft Virtual Earth Image Server and then downloading image tiles to approximately 0.3 meter resolution and unlinking the image to create a local
image. That is an almost completely automatic process within Manifold, easily accomplished with just a few mouse clicks on menu commands. Manifold automatically maintains projections throughout that process, so the image retains the same Universal Transverse Mercator projection originally used by the Virtual Earth image server.

To export the image we choose `File - Export - Image` and in the type box choose `Data Sources ()`.

In the resulting Data Source dialog we click the user / password pair data source that has already been set up in the Example: Configuring SQL Server 2008 topic. This connects to the server using a specified user name and password and desired database. Press `OK` (or simply double-click the data source).
The only Type available is Manifold geospatial image type, since SQL Server 2008 does not have its own image type akin to Oracle GeoRaster. The Manifold spatial database image storage mechanism automatically captures all projection information, so the image will be stored in the Universal Transverse Mercator projection it uses.

The Create Pyramids option is a very important option because it automatically creates intermediate views that enable very fast display of the image whether it is zoomed in or zoomed out.

The Tile size is automatically estimated by default and should not be changed except by experts. Manifold will automatically store the image as tiles to enable faster and more flexible data retrieval and will automatically recompose the image on the fly. The use of tiles is an internal storage mechanism that is completely invisible to users.

The Compression option likewise should not be changed. Manifold will automatically use lossless compression algorithms to reduce the space required for large images within the database. The reduction in space increases performance as well, because modern processors can decompress data faster than disk drives can fetch larger data.

Press OK. Depending on the speed of our computers, a few minutes will be required to store the image into SQL Server 2008. We can now launch a new Manifold session to illustrate how to link the image from SQL Server into Manifold.

We begin by choosing Tools - Database Console to launch the Database Console, pressing the Refresh button to refresh the connection to the data source.
Click on the image and click the Link button. [Note that if we prefer more friendly names in our database view we could use the Administrator Console to assign them.]

Almost instantly, a new linked image appears in the project pane. The database cylinder in the icon indicates the image is linked from an external source.
If we open the image we can see that it is indeed the image originally exported into SQL Server 2008. We can use the *Zoom Box* tool to zoom into the Northeast corner of the image.
Zooming occurs virtually instantly. We can zoom again for an even closer view of San Francisco Airport.
The image is so detailed that if we were to zoom to maximum resolution we could easily see every vehicle and in many cases individual people throughout many square miles of the San Francisco peninsula from the airport to Half Moon Bay. Despite the large size of the image, the power and speed of SQL Server together with Manifold are so fast that we can pan and zoom to any desired view virtually instantaneously.

Notes

Manifold spatial DBMS storage of images is so fast that if we have a fast DBMS like SQL Server 2008 available for image storage there is no gain in using compressed image technology like ECW.

For that matter, the technology in this topic scales so well that if we have the database server space and performance available to handle really large data, there is no need to manually chop up very large images into image libraries or other means of assembling larger images from smaller files. The performance available by combining Manifold with a fast DBMS allows a change in strategy for handling large files as compared to earlier technology.

For example, many government agencies and jurisdictions, from small cities to states and countries, are now compiling collections of very detailed aerial imagery. Such collections of images are often available to the public, if the public is able to handle the very large numbers of very large images involved. Such collections often include hundreds of images that are each hundreds of megabytes in size.

With older technology we might have had to deal with many large images by keeping the images separate so that each could be displayed with reasonable performance. Manifold storage of images in DBMS is so fast that an entire collection of hundreds of images could be combined into a single 100 GB+ image stored within a DBMS and Manifold would be able to display it almost instantly, using the spatial structures maintained by Manifold to fetch the right tiles for the right intermediate or full-resolution data for whatever view is required.
As a practical matter, most users will still keep some reasonable upper limit to the size of any one image in order to facilitate interchange and uploading into the DBMS, but there is no longer much of an upper limit in most applications to the size of images that, once stored in the DBMS, can be displayed within Manifold.

**Historical Note**

Gaspar de Portola (1717? - 1784?)

To the West of the Northern portion of San Andreas Lake stands Sweeney Ridge, upon the 1200 foot summit of which the expedition led by Gaspar de Portola on November 4, 1769, became the first Europeans to see San Francisco Bay.

For hundreds of years explorers had sailed past the rocky, narrow, difficult-to-see entrance to the greatest bay and natural anchorage in California without realizing the bay existed. For example, in 1580 Sir Francis Drake sailed past the entrance to San Francisco Bay and even put in for repairs to his ship, the Golden Hind, on the California coast just a few miles from the bay. Portola's overland expedition had walked past his earlier discovery of Monterey to find at last the great bay by land.

An intrepid explorer and able leader, Portola led numerous expeditions throughout Alta California, playing a key role in the founding of San Diego and Monterey and serving as Governor of Las Californias.

Manifold Spatial Extender for SQL Server

The Manifold Spatial Extender for SQL Server is a free extension module for SQL Server which provides spatial index functionality for Manifold System. Manifold Spatial Extender works with all versions of SQL Server starting with SQL Server 2005. Using Manifold Spatial Extender on SQL Server 2005 Express requires SQL Server 2005 Express SP2. The extender operates via the use of the common language runtime (CLR) integration feature of SQL Server.

SQL Server 2008 spatial users should note that the Manifold Spatial Extender is not required to utilize SQL Server 2008 spatial capabilities. The Manifold Spatial Extender is an add-in that allows Manifold-managed spatial infrastructure for SQL Server 2005 to operate with especially high performance. SQL Server 2008 spatial users should use native SQL Server 2008 spatial capability.

Download the Manifold Spatial Extender from links in the Manifold Updates page at http://www.manifold.net/updates or from other links on the manifold.net web site. The download provides the extender and a small installation utility to simplify installation of the extension and configuration of SQL Server.

The utility installs on the machine on which SQL Server runs. It works as an extension to SQL Server to provide more effective management of spatial indices using SQL Server resources. It does not provide built-in spatial operators to SQL Server or otherwise give SQL Server the ability to function as a spatial DBMS if Manifold is not used as a client.

The spatial extender automatically works together with Manifold as a client when Manifold connects to SQL Server via OLE DB. Manifold will automatically recognize the presence of the spatial extender and will use it to create and manage spatial indices when drawings are exported to SQL Server. A key benefit of the spatial extender is that it will automatically grow spatial indices as required. This makes it possible to add new objects to a drawing beyond the original extents of the drawing when it was uploaded.

Exporting a drawing using a Manifold drawing type with the geometry type set to Geometry or Geometry (WKB) to an instance of SQL Server with the Manifold spatial extender installed creates a server-side index managed by the extender. Using a server-side index provides for slightly better performance on reads, significantly better performance on writes, and makes writes more robust. The spatial extender also allows SQL Server to operate more efficiently in a spatial server / Manifold client relationship, so it lowers load on the server as well.

The Manifold spatial extender is a free utility made available to Manifold System licensees at no charge. It is nonetheless licensed software that is covered by the Manifold EULA. You may install it on as many machines as you like so long as your intent is to use it primarily with Manifold System.

SQL Server Alternatives

The purpose of the spatial extender is to give SQL Server 2005 users the fastest possible spatial indices when used with Manifold System. This will allow users committed to SQL Server to get started today with speedy spatial technology in a way that will in the future allow easy migration to SQL Server 2008 and will (hopefully) help avoid fragmentation of the pre-2008 SQL Server user base into many different, incompatible spatial extenders that collectively will be difficult to migrate to SQL Server 2008.

Note that there are two similar but significantly different Manifold approaches to providing spatial indices for SQL Server that are managed by Manifold (as opposed to using built-in Microsoft spatial facilities as are provided in SQL Server 2008 spatial). The first is using generic spatial indices as can be done with almost any DBMS. The second is installing the Manifold spatial extender in SQL Server and then using spatial indices managed by the spatial extender.

Both can even be used at the same time, although that would be a rare and unusual situation since the spatial extender swings into action automatically with Manifold once it is installed. However, if we began work with, say, SQL Server 2005 using generic spatial indices and then later on installed the spatial extender and uploaded some more drawings, in that case Manifold would use either the generic spatial index originally created or the new spatial index managed by spatial extender as the case may be for individual drawings. To avoid any guesswork as to what spatial index is being used it is strongly recommended that the spatial extender be installed on SQL Server 2005 installations and used from the beginning for all Manifold work.

As a practical matter, the spatial extender improves performance so much that it should always be used in SQL Server 2005 installations in preference to using generic spatial indices without the spatial extender. The manifold.net team knows of no disadvantage to using it. It is small, robust, very fast, perfectly integrated with Manifold and, of course, free of charge.
The spatial extender can work with Manifold drawings uploaded using either Manifold Geometry or OGC Geometry (WKB) geometry types. Because Manifold Geometry is a higher performance and more robust type than OGC Geometry (WKB), if direct interoperability with WKB applications is not a requirement then Manifold Geometry should always be used as the geometry type.

Manifold Spatial DBMS Facilities
Manifold Spatial DBMS Facilities
Before beginning this topic please read the Spatial DBMS and the Spatial DBMS Facilities topics for an introduction to spatial DBMS usage with Manifold.

In addition to working with a variety of spatial DBMS packages that have built in spatial capability, Manifold can confer upon almost any DBMS the ability to work as a spatial DBMS even if the DBMS vendor has not provided a native geometry type or other built-in spatial infrastructure. Manifold provides such capabilities by providing:

- **Manifold-managed geometry types** - Manifold can operate using either Manifold's own high performance GEOMETRY type or using an open standard such as OGC WKB.
- **Manifold-managed spatial indices** - Manifold can automatically create a spatial index that enables high performance spatial operations.

A spatial index declared by Manifold is processed mostly by the DBMS server and not by the client, so the performance attained will in general be set by the DBMS server, just as with a dedicated spatial DBMS. Editing a linked drawing will automatically update the spatial index.

The main usage of spatial DBMS storage when a GIS package front ends the DBMS is to extract an area of interest so that drawings of manageable size can be viewed and edited in the GIS client even though the DBMS contains a huge, seamless data set that otherwise would be too big to edit in its entirety. Filtering using the
spatial index to achieve extraction of an area of interest subset is likewise done mostly on the server so in this key task using a generic spatial index with GEOMETRY stored in the DBMS works quite well.

Manifold's ability to confer spatial DBMS capabilities to almost any DBMS does not require the use of Manifold's own GEOMETRY type. It could well use generic, non-Manifold, open standards for geometry types such as OGC WKB, and is often deployed in that way. Nonetheless, in this documentation the generic use of Manifold to confer spatial DBMS capability is referred to as Manifold spatial DBMS usage, to indicate it is a capability conferred by Manifold as opposed to being a built-in spatial DBMS capability like that with Oracle Spatial or SQL Server 2008 spatial capabilities.

Requirements

The following are required for Manifold spatial DBMS usage:

- A DBMS that can support binary data types, such as MySQL, Informix, SQL Server 2005, DB2 (not requiring IBM's Spatial Extender), Oracle (used as a regular DBMS exclusive of the built-in spatial features) or PostgreSQL (without spatial extensions).
- Although it is not required when using SQL Server 2005, it is strongly recommended that the Manifold Spatial Extender for SQL Server be installed on SQL Server machines for improved performance. The Manifold spatial extender is a free download.
- Manifold Enterprise Edition or higher edition is required to upload drawings into a DBMS and to confer spatial DBMS capability to that DBMS by creation of a spatial index and supporting facilities. Once such a drawing has been uploaded into the DBMS any Manifold edition can utilize that spatial data set with full spatial DBMS capabilities, including Area of Interest (AOI) windowing.
- Manifold Database Administrator Edition is required to use Administrator Console features such as providing friendly names for components stored in the DBMS. Once such features have been configured using Administrator Console, any Manifold edition can utilize them when connecting to that DBMS.

A Manifold spatial DBMS can store drawings, images and surfaces (which are stored as images).

Exporting and Linking a Drawing

This section uses SQL Server 2005 Express as an example of a generic, non-spatial DBMS. The procedure described will work with almost any modern DBMS.

How to Export a Drawing into SQL Server Express

1. In the project pane right click on the drawing and choose Export.
2. In the Export Drawing dialog choose Data Sources () in the Save as type box.
3. In the Data Source dialog click the data source for the SQL Server Express database you wish to use to highlight it. If a data source for the desired SQL Server Express database has not yet been added to the list of data sources provided in the Data Source dialog, please see the Data Source Dialog topic for instructions on adding a new data source to that dialog. Press OK.
4. In the Export Drawing dialog that pops up choose the fields to be exported with the drawing. By default, all fields except intrinsic fields are checked. Accept the other settings. (Note that the Create spatial index box is checked by default, which will create a spatial index for this drawing and thus confer upon SQL Server Express essential functionality as a spatial DBMS.) Press OK.

The drawing will be exported to SQL Server with a spatial index created.

We can now use Database Console to import or link the drawing into any Manifold project:

1. Launch Database Console and connect to the SQL Server data source.
2. We will see the drawing appear with a Manifold drawing icon next to it. If we have used Administrator Console (available within Database Administrator Edition) to give it a friendly name it will appear using whatever name was given to it in Administrator Console using the Properties dialog.
3. Import or link the drawing by clicking on it to highlight it and then pressing the Import or Link button in the toolbar. Because we declared a spatial index for the drawing we can choose to import or link objects only from a desired area of interest.
Manifold dialogs for export by default use the native Manifold **Geometry** type. Manifold's **Geometry** type is a high performance type that is just as efficient or more so than the native geometry types employed by various spatial DBMS vendors, but if desired some other geometry type such as **Geometry(WKB)** may be used and supported with a spatial index.

The above comments for use of SQL Server 2005 as a spatial DBMS using Manifold geometry and spatial indices apply to almost any big-name DBMS. For example, we can use MySQL in the same way.

**Spatial Indices**

Manifold can establish a spatial index within a DBMS for a database object (a table) that is to be treated as a drawing. A spatial index can only be created for a table that has a primary key. A primary key is created automatically whenever a drawing is exported to a DBMS and whenever the ID field is exported when a table is exported into a DBMS.

Once a spatial index is established for a table that is treated as a drawing, that index will be maintained primarily by the DBMS server. The spatial index allows the DBMS to fetch subsets of objects based upon location and extent, an obvious usage being to fetch manageable subsets of objects for a given area of interest from very large drawings.

A key limitation of using generic spatial indices is that they cannot grow outside the bounding box (the maximum East / West and North / South extents) of the original drawing for which they were created. This makes it impossible to add new objects to the drawing that extend beyond the original, bounding box. There are three ways to get around this limitation when using Manifold-managed spatial DBMS:

- Remove the spatial index, do the desired operation and then re-build the spatial index. Easy to do, but this requires the Administrator Console which is a part of more expensive Manifold editions such as Database Administrator edition and Ultimate Edition.
- Before uploading a drawing into the DBMS, create four temporary objects in the drawing that are at the corners of a larger region than ever will be needed for that drawing. Upload the drawing and the spatial index will be created to fit the larger region. After uploading, link the drawing and delete the temporary objects. This can be done with Enterprise edition, but it does require guessing at what will be the maximum extent required for the drawing.
- Use SQL Server and use the Manifold Spatial Extender for SQL Server. The Spatial Extender runs as a SQL Server add-in and will automatically grow spatial indices as required.

A spatial index declared by Manifold is processed mostly by the DBMS server and not by the client, so the performance attained will in general be set by the DBMS server, just as with a dedicated spatial DBMS. Editing a linked drawing will automatically update the spatial index.

The main usage of spatial DBMS storage when a GIS package front ends the DBMS is to extract an area of interest so that drawings of manageable size can be viewed and edited in the GIS client even though the DBMS contains a huge, seamless data set that otherwise would be too big to edit in its entirety. Filtering using the spatial index to achieve extraction of an area of interest subset is likewise done mostly on the server so in this key task using a generic spatial index with **Geometry** stored in a DBMS works quite well.

**Examples**

The following examples use Microsoft SQL Server Express 2005 as a default example of a DBMS. The examples assume the DBMS has been installed using defaults as set forth in the SQL Server Express Edition topic, that the Manifold spatial extender has been installed on the server machine and that a data source has been created in the **Data Source** dialog to connect to that SQL Server Express database as set forth in the Data Source dialog topic.

Example: Storing a Drawing in Manifold Spatial DBMS

This example uses Microsoft SQL Server Express 2005 as a default example of a non-spatial DBMS to which spatial DBMS capabilities can be added by using Manifold. Such usage is referred to as Manifold Spatial DBMS since Manifold is used to manage the storage, even though the actual geometry stored might be some non-Manifold type such as OGC WKB.

This example assumes the SQL Server Express 2005 DBMS has been installed using defaults as set forth in the SQL Server Express Edition topic and that a data source has been created in the Data Source dialog to connect to that SQL Server Express database as set forth in the Data Source dialog topic.

As advised in the Spatial DBMS topic, users are strongly encouraged to install the Manifold Spatial Extender for SQL Server when using SQL Server 2005 as a spatial DBMS. Procedures using with the spatial extender installed or not are identical, but use of the Manifold spatial extender will improve performance of spatial indices.

Manifold Enterprise Edition is required to export a drawing into a non-spatial DBMS in a way that grants spatial DBMS capabilities. Thereafter, any Manifold edition can utilize those spatial DBMS capabilities for drawings stored using Enterprise Edition. In addition, Manifold Database Administrator Edition provides very useful and convenient features that may be employed by administrators to configure DBMS storage to make life easier for ordinary users using other Manifold editions. Database Administrator Edition is required for the Administrator Console procedures shown later in this example.

Export a Drawing to SQL Server Express 2005

In this example we use Manifold Enterprise Edition to export a sample drawing of Mexico to SQL Server Express 2005:

In the project pane we right click on the drawing and choose Export.

In the Export Drawing dialog we choose Data Sources in the Save as type box.
In the **Data Source** dialog we click on the entry for SQL Server and then press **OK**.

[This screen shot assumes we have previously created an entry for our SQL Server connection as set forth in the Data Sources dialog topic and have named it **Local SQL Server Express**.]

We can see that this particular Manifold installation also has a connection configured to an Oracle Express data source.]
In the Export Drawing dialog we accept defaults and press OK. All fields (columns) will be exported except intrinsic fields. The drawing will be uploaded into the DBMS using standard Manifold geometry types and a spatial index will be created.

**Important:** When exporting a drawing to a spatial DBMS it is best if the drawing does not contain a column called OID. This name is used by Manifold as the default name for the object identity field. If we like, we can still export a drawing that contains such a column but then we will have to remember in the export dialog to change the name of the identity field to something else.

While that is certainly easy enough to do, it is also easy to forget to do in which case the export will fail and we will wonder why. Also, it is useful to always assume that an OID field is the identity field. Therefore, it is strongly recommended to treat this field name as a reserved name.

The Export Drawing dialog gives us some options as to how we store the geometry. The Type box near the top of the dialog in this case will have only one choice, Manifold, unless the DBMS to which we are exporting has native spatial DBMS capabilities. If we are exporting to a non-spatial DBMS such as SQL Server 2005 (as opposed to SQL Server 2008 with the new spatial capability Microsoft has announced for SQL Server 2008) the only choice will be Manifold, meaning that Manifold will provide the spatial DBMS capabilities. If we were exporting to a DBMS with native spatial capabilities, such as Oracle, there would be a choice of the native spatial DBMS type as well, for example, Oracle, in addition to the Manifold choice.
Manifold can support non-Manifold geometry types for drawing storage and such are available within the Geometry type box even though it is a terrible idea for beginners not to use the default choice, Geometry, which chooses the Manifold Geometry type. Manifold geometry is by far the fastest, most robust and most modern of any of the various geometry types available.

In certain rare circumstances experts may prefer to choose Geometry(WKB) to use OGC WKB geometry or even Geometry (SHP) for an ESRI-style, "shapefile"-derived geometry type. If we pick something other than Geometry we are asking for trouble, as the other geometry types don't do as good a job of storing coordinate information as Manifold Geometry. There might be some justification for experts to use WKB if they like OGC ways of doing things and are willing to deal with the difficulties involved, but there is no good reason to use Geometry(SHP) outside of very unusual and exotic applications.

**Link a Drawing from SQL Server Express 2005**

Now that we have a drawing in SQL Server we can import it or link it into Manifold using any Manifold edition. The following sequence, for example, can be used in Manifold Personal Edition or any other Manifold edition.

We open a project and launch Database Console. Within Database Console we choose the SQL Server Express installation from the Data Source dialog if it is not already loaded into the Data Source box. We press the Refresh button to see the contents of the DBMS server.
Database Console shows us the contents of the server. The drawing will appear using a Manifold drawing icon.

By default, Database Console will show us all of the contents of the server. If our budget allows, we can use the Administrator Console feature from Manifold Database Administrator Edition to configure the database to use friendly names so that the display is simplified for new users. See an example below.

To link the drawing into our project we click on it to highlight it and then we press the **Link** button in the Database Console toolbar.
The Import / Link Options dialog allows us to specify a name to use for the linked component and to choose between using all objects or only using those objects which fall within a desired area of interest. Note that area of interest specification, a serious spatial DBMS capability, is available to us even though the DBMS we are using is not a DBMS with built-in spatial features and even though we might not be using Manifold Enterprise Edition. Press OK to continue.

The result is that a new, linked drawing appears in the project.

If we click this drawing open we see it is indeed the sample Mexico drawing exported in the previous part of this example. It has been linked complete with all projection information exactly as it was when exported.

Configure a Drawing using Administrator Console

Being able to export drawings into almost any DBMS with true spatial DBMS capabilities available upon import is extremely useful. However, as seen above the example is limited for two main reasons: First, it exposes complicated DBMS objects and names which might potentially confuse beginning users and second, it does not allow formatting for the linked drawing to be stored on the DBMS server.
We can add both capabilities by using Administrator Console, a feature provided by Manifold Database Administrator Edition and by Ultimate Edition. Once drawings are so configured using Database Administrator edition, thereafter any Manifold edition can connect to the database and use friendly names and formatting stored on the database. For that reason, organizations that have many users using drawings stored within databases will usually have a few Manifold Database Administrator or Ultimate licenses for use by managers to configure drawings within the database to use friendly names and to allow formatting, while the majority of their licenses are Enterprise or Universal licenses.

We will first turn on storage of formatting within the DBMS and then provide a friendly name (component name) to use.

Launch Manifold Database Administrator Edition and connect to the SQL Server Express database with Administrator Console. Press Refresh to see the contents of the database.

We note that the column showing format status is not turned on in the display. To turn it on, we press the Columns button.
In the **Columns** dialog we check the **Format** box to display that column.

We double-click into the **Format** cell for the entry for the Mexico drawing and set the **Format** value to **Yes**.

Note that Administrator Console shows all database objects using their database names. It's easy to tell which are drawings because they will have a projection and a spatial index value.

Next we will provide a component name, that is, a friendly name.
To do so, double-click into the Component cell for the Mexico drawing and provide a desired name. For lack of anything better coming to mind, we will use the name Mexico. This name will be displayed when Database Console shows the contents of the database.

**Linking a Drawing Configured with Administrator Console**

Now that the drawing in the database has been configured with Administrator Console we can use any Manifold edition to import it or link it, with the benefits of friendly names and formatting on the database.

Launch any Manifold System edition, open a project and launch Database Console. Connect to the SQL Server Express database used and press the Refresh button.

Database Console will see that component names are available in the database and will automatically engage the Component View button to display database items in the console view using friendly names. Instead of a list of confusing database objects we see Manifold components using friendly names as configured by Administrator Console in the previous parts of this example. Excellent!

To link a drawing, click on it to highlight it and then press the Link button.
When we open the drawing we can apply formatting, and the formatting will be stored on the database so that any other user linking the drawing will see that formatting.

Notes

The procedures used herein will work with almost any DBMS that can store binary data, such as MySQL, Informix or others. SQL Server Express 2005 is used as a convenient example since many people have it already. Oracle Express or DB2 could have been used just as conveniently. However, since Oracle Express includes built-in Locator capability (Oracle's spatial DBMS technology for drawings as in Oracle Spatial) and DB2 Express-C can be equipped with the free DB2 Spatial Extender, we have used SQL Server 2005 to provide an example of a modern DBMS that does not include built-in spatial DBMS.

When discussing spatial storage in SQL Server one should keep in mind there are several possibilities depending upon which version of SQL Server is being used and which spatial technology is employed. See the discussion in the Spatial DBMS topic.

Example: Storing an Image in Manifold Spatial DBMS

This example uses Microsoft SQL Server Express 2005 as a default example of a non-spatial DBMS to which spatial DBMS capabilities can be added by using Manifold. Such usage is referred to as Manifold Spatial DBMS since Manifold is used to manage the storage.

This example assumes the SQL Server Express 2005 DBMS has been installed using defaults as set forth in the SQL Server Express Edition topic and that a data source has been created in the Data Source dialog to connect to that SQL Server Express database as set forth in the Data Source dialog topic.

As advised in the Spatial DBMS topic, users are strongly encouraged to install the Manifold Spatial Extender for SQL Server when using SQL Server 2005 as a spatial DBMS. Procedures using with the spatial extender installed or not are identical, but use of the Manifold spatial extender will improve performance of spatial indices.

Manifold Enterprise Edition is required to export an image into a non-spatial DBMS in a way that grants spatial DBMS capabilities. Thereafter, any Manifold edition can utilize those spatial DBMS capabilities for images stored using Enterprise Edition. In addition, Manifold Database Administrator Edition provides very useful and convenient features that may be employed by administrators to configure DBMS storage to make life easier for ordinary users using other Manifold editions. Database Administrator Edition is required for the Administrator Console procedures shown later in this example.

Export an Image to SQL Server Express 2005

In this example we use Manifold Enterprise Edition to export a sample image to SQL Server Express 2005:

We open a project with the image.

If we open the image we see it shows portion of the Microsoft campus in Redmond, Washington.
This image is reasonably well detailed, at about 0.3 meter resolution, as we can see by zooming in.

To export the image to a database we right click on the image in the project pane and choose Export.

In the Export Image dialog we choose Data Sources in the Save as type box.
In the **Data Source** dialog we click on the entry for SQL Server and then press **OK**.

This screen shot assumes we have previously created an entry for our SQL Server connection as set forth in the Data Sources dialog topic and have named it **Local SQL Server Express**.

We can see that this particular Manifold installation also has a connection configured to an Oracle Express data source.

In the **Export Image** dialog we accept defaults and press **OK**. The image will be uploaded into the DBMS using standard Manifold spatial DBMS surface storage technology for raster data sets (images and surfaces). Manifold stores images as tiles so that subsections of images can be retrieved very rapidly. The default **Tile size** recommended by Manifold may be adjusted up or down, but usually is the best choice.

The option to **Create Pyramids** creates pre-computed, intermediate views, called **pyramids**, which enable faster display of very large images when zoomed out. **Compression** using the default **Deflate** option is a good
idea because the computational cost of decompression is negligible and there is no image quality lost, yet having a smaller amount of data in the database not only saves disk space but it helps the DBMS perform faster.

**Note:** Export of images to databases is robust. For example, exporting an image to a database as a tiled table (the actual storage mechanism used within the database) correctly rolls back all changes upon a failure.

**Link an image from SQL Server Express 2005**

Now that we have an image in SQL Server we can import it or link it into Manifold using any Manifold edition. The following sequence, for example, can be used in Manifold Personal Edition or any other Manifold edition.

We open a project and launch Database Console. Within Database Console we choose the SQL Server Express installation from the Data Source dialog if it is not already loaded into the Data Source box. We press the **Refresh** button to see the contents of the DBMS server.
Database Console shows us the contents of the server.

**Important:** In this example, we have continued using the same SQL Server Express installation employed in the Example: Storing a Drawing in Manifold Spatial DBMS topic. At the end of that example we used Administrator Console to configure a friendly name for the drawing that was stored. When Database Console connects to a DBMS that contains friendly names it automatically turns on with the Component View button enabled, so that only friendly names are shown and database object names that might be confusing to inexpert users are hidden.

Uploading an image into a DBMS uploads it without a friendly name until we configure a friendly name using Administrator Console. To see the image that was just uploaded we will have to turn Component View off to see everything in the database.
The image will appear using a Manifold image icon. To link the image into our project we click on it to highlight it and then we press the **Link** button in the Database Console toolbar.

Note that unlike the case of importing or linking a drawing as seen in the previous Example, no **Import / Link Options** dialog appears when importing or linking an image to allow specifying a subset of the image for the area of interest. The reason is that the nature of image storage technology using tiles is such that at any moment there is, in effect, a virtual area of interest subset acquisition from the database, with tiles being fetched as needed for whatever view is commanded through panning and zooming a display window.

If we click this image open we see it is indeed the image exported in the previous part of this example. It has been linked complete with all projection information exactly as it was when exported.

**Configure an image using Administrator Console**

Being able to export images into almost any DBMS with true spatial DBMS tiled storage is extremely useful. However, as seen above the example is limited because it exposes complicated DBMS objects and names which might potentially confuse beginning users.

We can avoid complicated database names by using friendly names (component names) as provided through Administrator Console, a feature that is part of Manifold Database Administrator Edition and by Ultimate Edition. Once images are so configured using Database Administrator edition, thereafter any Manifold edition can connect to the database and use friendly names. For that reason, organizations that have many users using images stored within databases will usually have a few Manifold Database Administrator or Ultimate licenses for use by managers to configure images within the database to use friendly names, while the majority of their licenses are Enterprise or Universal licenses.

Using Database Administrator Edition we will specify a friendly name (**component name**) to use. Launch Manifold Database Administrator Edition and connect to the SQL Server Express database with Administrator Console. Press **Refresh** to see the contents of the database.
Administrator Console shows all database objects using their database names. It's easy to tell which are images because they will have a Manifold image icon.

To provide a component name, that is, a friendly name, double-click into the Component cell for the Microsoft image and provide a desired name. For lack of anything better coming to mind, we will use the name Microsoft HQ. This name will be displayed when Database Console shows the contents of the database.

**Linking an image Configured with Administrator Console**

Now that the image in the database has been configured with Administrator Console we can use any Manifold edition to import it or link it with the benefit of friendly names.
Launch any Manifold System edition, open a project and launch Database Console. Connect to the SQL Server Express database used and press the **Refresh** button.

Database Console will see that component names are available in the database and will automatically engage the Component View button to display database items in the console view using friendly names. Instead of a list of confusing database objects we see Manifold components using friendly names as configured by Administrator Console in the previous parts of this example.

To link an image, click on it to highlight it and then press the **Link** button.

![Microsoft HQ](image)

The result is an image within the project pane that is identical to the original image we exported.

**Notes**

New users may wonder about the need to switch off **Component View** to see the newly-uploaded image before a friendly name has been specified with Administrator Console. Would that not be an inconvenience to most users?

As a practical matter, no. When Manifold users have Administrator Console available it is used to assign friendly names when drawings, images or surfaces are uploaded into a database. In that case, the **Component View** button will always be on and users will always see the contents of their databases using friendly names. Friendly names are such a convenience that most users, even experts, strongly prefer them to raw, database names for items within a database.

In contrast, if a Database Administrator Edition license has not been acquired then no friendly names will be in use, the **Component View** button will always be off and users will always see the contents of their databases using the naming style used by that database. Many users will not mind that if their budgets do not allow for a Database Administrator Edition license.

See also the notes on SQL Server Express as an example DBMS at the end of the previous Example topic.
This example uses SQL Server 2005. We can also use a spatial DBMS such as SQL Server 2008 to store images using Manifold spatial capabilities. See the Example: Storing an Image in SQL Server 2008 topic for such an example.

Example: Storing a Surface in Manifold Spatial DBMS

This example uses Microsoft SQL Server Express 2005 as a default example of a non-spatial DBMS to which spatial DBMS capabilities can be added by using Manifold. Such usage is referred to as Manifold Spatial DBMS since Manifold is used to manage the storage.

This example assumes the SQL Server Express 2005 DBMS has been installed using defaults as set forth in the SQL Server Express Edition topic and that a data source has been created in the Data Source dialog to connect to that SQL Server Express database as set forth in the Data Source dialog topic.

As advised in the Spatial DBMS topic, users are strongly encouraged to install the Manifold Spatial Extender for SQL Server when using SQL Server 2005 as a spatial DBMS. Procedures using with the spatial extender installed or not are identical, but use of the Manifold spatial extender will improve performance of spatial indices.

Manifold Enterprise Edition is required to export a surface into a non-spatial DBMS in a way that grants spatial DBMS capabilities. Thereafter, any Manifold edition can utilize those spatial DBMS capabilities for surfaces stored using Enterprise Edition. In addition, Manifold Database Administrator Edition provides very useful and convenient features that may be employed by administrators to configure DBMS storage to make life easier for ordinary users using other Manifold editions.

Exporting a surface is essentially identical to exporting an image as shown in the Example: Storing an Image in Manifold Spatial DBMS topic in that surfaces are stored within databases as though they were images, but with a Height channel. The difference between surfaces and images arises upon import, when the Height channel is imported to recreate the surface. At the present time, surfaces cannot be linked from a database.

Export a surface to SQL Server Express 2005

In this example we use Manifold Enterprise Edition to export a sample surface to SQL Server Express 2005:

We open a project with the surface to be exported.
If we open the surface we see it shows the Montara Mountain sample elevation data set. The surface has been colored with a palette using the View - Display Options dialog.

To export the surface to a database we right click on the surface in the project pane and choose Export.

In the Export Surface dialog we choose Data Sources in the Save as type box.

In the Data Source dialog we click on the entry for SQL Server and then press OK.

[This screen shot assumes we have previously created an entry for our SQL Server connection as set forth in the Data Sources dialog topic and have named it Local SQL Server Express.

We can see that this particular Manifold installation also has a connection configured to an Oracle Express data source.]
In the Export Surface dialog we accept defaults and press OK. The surface will be uploaded into the DBMS using standard Manifold spatial DBMS surface storage technology for raster data sets (images and surfaces). As with images, Manifold stores surfaces as tiles so that subsections of surfaces can be retrieved very rapidly. The default Tile size recommended by Manifold may be adjusted up or down, but usually is the best choice.

The option to Create Pyramids creates pre-computed, intermediate views, called pyramids, which enable faster display of very large surfaces when zoomed out. Compression using the default Deflate option is a good idea because the computational cost of decompression is negligible and there is no surface quality lost, yet having a smaller amount of data in the database not only saves disk space but it helps the DBMS perform faster.

Import a surface from SQL Server Express 2005

Now that we have a surface in SQL Server we can import it into Manifold using any Manifold edition. The following sequence, for example, can be used in Manifold Personal Edition or any other Manifold edition.

We open a project and launch Database Console. Within Database Console we choose the SQL Server Express installation from the Data Source dialog if it is not already loaded into the Data Source box. We press the Refresh button to see the contents of the DBMS server.

Important: In this example, we have continued using the same SQL Server Express installation employed in the Example: Storing a Drawing in Manifold Spatial DBMS topic and in the Example: Storing an Image in Manifold Spatial DBMS topic. At the end of those examples we used Administrator Console to configure a friendly name for the drawing or the image that was stored. When Database Console connects to a DBMS that contains friendly names it automatically turns on with the Component View button enabled, so that only friendly names are shown and database object names that might be confusing to inexpert users are hidden.
Uploading a surface into a DBMS uploads it without a friendly name until we configure a friendly name using the Administrator Console. To see the surface that was just uploaded we will have to turn Component View off to see everything in the database.

The surface will appear using a Manifold image icon, because it exists within the DBMS as a raster data set, the same as images. To import the surface into our project we must first click on the + icon to the left of the image icon to expand the entry so that the different channels of the image can be seen. We can then click on the Heights channel to highlight it and then we press the Import button in the Database Console toolbar.
The result is that a new surface appears in the project.

Note that unlike the case of importing or linking a drawing as seen in the Example of storing drawings to a DBMS, no Import / Link Options dialog appears when importing a surface to allow specifying a subset of the surface for the area of interest.

If we click this surface open we see it is indeed the surface exported in the previous part of this example, albeit with no formatting specified. It has been imported complete with all projection information as it was when exported.

Notes

If we have Database Administrator Edition we can configure surfaces stored in databases with friendly names just as we can with drawings and images. See the Example: Storing an Image in Manifold Spatial DBMS topic for an example of configuring friendly names.

New users may wonder about the need to switch off Component View to see the newly-uploaded surface before a friendly name has been specified with Administrator Console. Would that not be an inconvenience to most users?

As a practical matter, no. When Manifold users have Administrator Console available it is used to assign friendly names when drawings, surfaces or surfaces are uploaded into a database. In that case, the Component View button will always be on and users will always see the contents of their databases using friendly names. Friendly names are such a convenience that most users, even experts, strongly prefer them to raw, database names for items within a database.

In contrast, if a Database Administrator Edition license has not been acquired then no friendly names will be in use, the Component View button will always be off and users will always see the contents of their databases
using the naming style used by that database. Many users will not mind that if their budgets do not allow for a Database Administrator Edition license.

Programming

Programming Manifold

Manifold may be programmed in several ways:

- "Ad hoc" programming using Active Columns in tables or ViewBots.
- Using SQL queries in the classic DBMS way to alter table structure and otherwise make updates.
- Using Spatial SQL for sophisticated spatial operations on vector (drawings) or raster (images and surfaces) data or a combination thereof.
- Writing scripts using ActiveX scripting languages such as VBScript (the scripting edition of Visual Basic), JScript (also called JavaScript), Perl or Python, or .NET languages such as C#, VB .NET or JScript .NET. Scripts components may be created for Forms or may be created as standalone Script components.
- Scripts may invoke and control user interface elements such as dialogs. See the User Interface Scripting topic.
- Calling Manifold System from external programs written in standard languages like Visual Basic and Visual C++ or their .NET language equivalents, such as Visual Basic .NET, C#, Iron Python, etc.
- Adding scripts (which may call external COM objects) as custom toolbar buttons or menu items. See the Add-Ins topic for information on adding new toolbar buttons or menu commands.
- Programming in ASP or ASP.NET pages to create custom web pages that utilize Manifold IMS to create dynamic, Manifold-enabled web sites. Web applications on intranets are quite often the fastest, easiest and lowest cost way of creating customized GIS applications for distribution and use within an organization.

There is no additional programming language or toolkit that must be purchased in order to program Manifold. Every system includes the ability to use ActiveX languages or .NET languages to write sophisticated, forms-based programs using standard Windows controls. If you do have an external programming environment such as Visual Studio .NET, you can use that as well without the need to purchase any other options. You can even get a free Express version of Visual Studio from Microsoft.

Manifold also provides a Debugger for ActiveX scripting similar to those used in professional programming environments. The Debugger allows stepping through multiple scripts with automatic stops at breakpoints, paused execution and stepping into, over and out of routines. The Call Stack, Variables and Watches panes provide dynamic, editable displays of variables, functions, computed values and contexts. The Debugger works with VBScript, JScript and any other ActiveX scripting engine that supports Microsoft debugging calls. It is not used when scripting in a .NET language like C#.

Advice for Applications Developers

Many developers are creating commercial products based upon Manifold. There are two approaches, standalone applications or web applications, which in some sophisticated applications may be combined:

Standalone Applications

In this traditional way of creating and distributing applications a developer acquires however many Manifold licenses are required for the development team and an application is created that utilizes Manifold features through the API set forth in the Programming Reference chapter.

The application is then deployed using Manifold runtime licenses, which include the full Manifold API but not the Manifold GUI. A Manifold runtime license must be installed on every machine on which an application that calls Manifold facilities is deployed. That will require some means of keeping track of the serial number for each license and arranging for activation of each runtime license. Different developers have different preferences on how to arrange for installation and activation of the Manifold runtime license.

At one end of the spectrum are developers who tell their customers to acquire, install and activate a Manifold runtime license before installing the developer’s product. In this scenario the developer leaves it up to the customer to buy and to install and activate the necessary Manifold runtime. There are advantages and disadvantages to this strategy.

On the plus side, this strategy reduces the developer’s use of cash to acquire and inventory Manifold runtime licenses and it eliminates the need for the developer to figure out how to acquire a Manifold license and then
remotely install and activate it for the customer. However, on the minus side this strategy does risk that a potentially inexperienced customer might not license the right Manifold product or install and activate it correctly. It also makes it clearly known to the customer that Manifold is the engine used for the application. A final disadvantage is that if the developer does not copy protect the application then he or she will soon find out that a significant percentage of customers buy one application but then will acquire many Manifold runtime licenses to enable installation of that one application on many machines.

Many developers will charge much higher prices for their application than the price of a Manifold runtime license and so they will not want it advertised that their application is based upon Manifold. Such developers will prefer to handle all parts of the installation and will install the Manifold runtime as part of their application's installation. There are many different approaches to managing serial numbers and activating the runtime installation.

One approach favored by developers who send personnel to install applications and train customers is to have the developer's own personnel install and activate the runtime. A second approach favored by developers with applications that are intended to be installed by the customer is to use an automated approach to Manifold activation.

The usual automated approach is that the developer creates a small, web-hosted DBMS application that contains the serial numbers acquired by the developer for the Manifold runtime licenses acquired by the developer. When the developer sells an application he or she assigns the new customer a hash code that corresponds to an available license. The developer's application installation script includes a dialog in which the customer provides the hash code, allowing the installation script to connect to the developer's DBMS, grab the serial number associated with that hash code and then activate the Manifold runtime (using command line activation) with that serial number.

Either technique allows the developer to utilize Manifold's serial number and Activation key copy protection mechanism as a handy way of providing copy protection for their own applications as well (since the developed application won't run without an authorized Manifold runtime license). Developers are sometimes annoyed with the need to deal with Manifold activation until they realize how that mechanism discourages piracy of their own applications, at which point they become enthusiastic supporters of that Manifold mechanism.

See the Activation Keys and Serial Numbers topic for a discussion of the Manifold serial number and activation key mechanism. See the Developing Applications topic for specific advice of interest when developing standalone applications.

Web Applications

When customers are known to have an Internet connection available, many lightweight applications can be implemented as web applications that utilize Manifold IMS on a web server and free web browsers on client machines. In this case a developer will acquire Manifold licenses as needed for the development team and then deploy the application to a web server using either a runtime license or a regular license. Developers will often deploy to a web server using a full license because costs are so low in any case that they deem it worthwhile to have a fully interactive Manifold GUI available on the web server should it ever be necessary for debugging purposes.

There are many advantages to such an architecture, the most obvious being that there is near-zero cost for Manifold since client-side software consists of a free browser and the server-side software could consist of only a single Manifold runtime license. There are other advantages to web applications as well:

- **Control over data** - The applications developer can retain full control over data because it is resident on the server and need not be installed on client machines.
- **Easier data updates** - Changing data on the server instantly updates all client usage without need to distributed updated files to client machines.
- **Easier application updates** - Updating the application on the server updates the application for all clients.
- **Potential for subscription model** - A web based application allows business models that charge for application usage in real time. This allows conversion of what is usually a one-time purchase into a subscription or annuity, which can assist cash flow for developers.
- **No redistribution issues** - Because no vendor software is used client-side there is no need for the applications developer to deal with redistributing or activating runtime licenses into client machines.

Of course there are disadvantages to web applications as well. Web applications are limited by Internet bandwidth to lower performance applications than are possible with standalone applications. See the GIS and Networking and the What about Ajax? topics for a discussion of the issues involved.
Web applications can also require a greater amount of server-side programming in comparison to the local programming many programmers are familiar with using tools like the Microsoft Express series.

**Advice for New Programmers**

Because Microsoft languages and language standards are used within Manifold, to program Manifold we need to understand the Microsoft approach to languages and to Windows programming. In addition, although Manifold System is itself coded entirely in Microsoft Visual C++, many applications developers prefer to work with Microsoft's Visual Basic languages for customization of applications.

Experienced programmers already have strong opinions as to the languages they prefer. In modern times, most experienced programmers are already working with Visual Studio .NET using some .NET language they like. In contrast, beginners often start with scripts using some scripting language and, in the Microsoft world, often begin using some version of Visual Basic. It is therefore important to understand the differences between various versions of Visual Basic offered by Microsoft. This topic provides some guidance for beginners, to help them avoid traps such as coding in VBA.

**Microsoft BASIC and Scripting Languages**

At the present time, there are several Microsoft languages of interest to beginning Windows developers who do scripting or who prefer to work with a BASIC language:

- **Javascript (JScript or JScript .NET)** - JScript is Microsoft's superb implementation of the widely used Javascript language, a scripting version of the Java language. Javascript is a favorite of "cross platform" writers creating Internet applications who wish to write scripts that work with many different browsers on Windows and non-Windows operating systems. JScript is an interpreted language that executes within an ActiveX scripting engine.

- **Visual Basic (VB or VB .NET)** - A full-fledged development language that is normally used within Microsoft's Visual Studio development environment. Visual Basic is a compiled language. Many professional applications that are not coded in Visual C++ are coded in Visual Basic. Visual Basic includes superb editing, forms creation and other accessories that facilitate use of this language.

- **Visual Basic Scripting Edition (VBScript)** - A subset of Visual Basic that is a very widely used scripting language, in part because it comes free with every copy of Microsoft's Internet Explorer browser and may be freely redistributed with applications created using Visual Studio. VBScript is the scripting language of choice (with JScript being a second choice) for Microsoft web applications. It is the main language used with ActiveX scripting. Microsoft's push into Internet has made VBScript immensely popular and well supported by third parties with numerous books and objects. An interpreted language, VBScript has become so popular that third parties (such as manifold.net) are now extending it with forms creation and other tools. VBScript is virtually identical to VB so expertise in either VB or VBScript is automatically useful in the other language as well. VBScript has also emerged as the main language used to configure and customize Microsoft's Enterprise class servers.

- **Visual Basic for Applications (VBA)** - A VB variation that likely would have no life were it not bundled with Microsoft's own Office applications. This is a Visual Basic of sorts that is embedded within an application. It is an interpreted language, so any programs or add-ins written in it automatically deliver the source code for the add-in to every user (a real showstopper for most commercial developers). In recent years Microsoft has tried to sell VBA under license for use by third parties; however, despite a marketing push by Microsoft as of this writing fewer than 200 non-Microsoft applications use VBA. There are two main reasons VBA has not caught on: For professional applications, VBA has a high hassle-factor without offering the benefits of true Visual Basic or Visual Studio. For casual use VBA is not significantly better than VBScript while costing far more (potentially adding hundreds of dollars of end user cost) and being clumsier. At one point, VBA had a richer set of tools than VBScript but the surging popularity of VBScript has erased that advantage.

Even within Office application programming, VBA is being pushed aside by programming in real VB or the use of VBScript. As popular as VBA has been for amateur programmers in the Office application programming niche, the engineering team at manifold.net believe that VBA is a technological and business dead-end. We think that the highest value approach to programming with applications in Microsoft operating systems is a two-fold approach using VBScript and VB:

- Use Visual Basic Scripting or JScript for rapid scripting within Manifold. There is so much support for these languages as a result of the growth of Internet that they are clearly the way to go for casual scripting. By adding some elegant support facilities such as Manifold's form designer, they can be used to do everything VBA can do, but without the overhead, cost, hassle-factor and weirdness of VBA.
Scripts written in VBScript or JScript are perfect for use within Active Columns as well. If possible, move to the .NET versions of these languages in order to take advantage of .NET capabilities.

- **Use Visual Basic or Visual C++ within Visual Studio** for extensive applications development with Manifold. This allows source code protection within compiled code, the speed advantages of compiled code and most importantly the ability to use the full array of professional code-warrior tools available within Studio. SourceSafe alone is worth the jump to Studio when working in teams and the Visual Studio editor is a dream come true.

- Of course, when coding in .NET environments (a good idea), use Visual Basic .NET or JScript .NET or C#, the .NET equivalents of the above two strategies. Although coding with .NET involves a steeper learning curve for the complete beginner, almost all professional programmers working in Microsoft environments are writing .NET code. If writing code is an important part of your professional life, the sooner you get a copy of Visual Studio .NET and get your head around .NET, the better.

The above, two-fold approach appears to be the strategy chosen by Microsoft itself for all of its next generation products. A review of Microsoft's online Knowledge Base and other resources on the www.microsoft.com site shows extensive Microsoft use of VBScript or Visual Studio tools for .NET and the Enterprise servers such as SQL Server, Commerce Server and Exchange Server, but virtually no new work in VBA outside of a handful of consumer examples for Office.

Users of Visual Studio need no encouragement for coding in this superb environment. For world-class, professional program development, get a copy of Visual Studio .NET and learn to code in .NET using Visual C++ or Visual Basic .NET. Microsoft makes it easy for people to get started by providing free downloads of the Express version of Visual Studio. Go for it!

To support the use of VBScript for casual scripting, manifold.net has developed forms-based, drag and drop tools drawn from our experience with Windows and Visual Studio that make it very easy to write scripts of amazing sophistication and power in VBScript. In fact, VBScript is so good and the Manifold development environment so easy to use, it is quite likely that professional developers as well as proficient amateurs might reach first for VBScript even for complex tasks.

Using VBScript also means that no additional software is required to program scripts of great sophistication in Manifold. There is no need to purchase Visual Basic or other Visual Studio components, no need to buy any third party accessories, no SDK, and no embedded license fee for VBA. If you have Manifold System you can program right away using true Windows, event-driven and forms-based programming methods. VBScript is a fine "first language" to learn for someone who has never programmed before. It's fast, easy, fun and when it is used with ActiveX controls it is extremely powerful for many practical purposes.

VBScript scripts in Manifold can call any standard ActiveX object if desired. For example, one can add a third party ActiveX control to a form that draws a custom picture of some sensing instrument's readout. There are many thousands of freeware, shareware and inexpensive ActiveX controls we can use in Manifold scripts. Manifold provides a large "starter set" of fun controls like calendars, toolbars and other useful items.

Although Manifold scripts may be written in VBScript or JScript (or even PERL or Python) all of the documentation examples and other support resources from Manifold are based on VBScript. Technically, any ActiveX scripting engine language that you have installed in your machine can be made to work. However, to keep documentation and tech support down to a realistically manageable size we focus on VBScript. There is no technical support available from manifold.net for scripting languages other than VBScript. If you choose to work in other languages it is up to you to learn enough about VBScript and Microsoft methods to figure out how to translate what is said in a VBScript context to your language.

This documentation also assumes the programmer is fluent in Windows programming. Windows programming is based on an **event-driven** model, which is very different than traditional, "procedural" applications programming. Although there are tips scattered throughout this documentation (including the brief introduction below), if you are not fluent in Windows programming you will need to get some good books on Visual Basic, VBScript, Windows, ActiveX and other key Microsoft products and concepts. There are hundreds of good choices. Because Manifold uses standard Microsoft languages and methods you have an entire world of resources to utilize.

One small caveat: because VBScript is so popular for web stuff scripting, many books will discuss it in the middle of lots of other talk about HTML, Active Server Pages (ASP) and other web topics. That's OK. The same characteristics that make VBScript a good first choice in web programming also make it ideal for casual scripting in Manifold as well. The only differences between VBScript books with a web orientation and VBScript use in Manifold will be the environment within which one actually writes the scripts.

**Windows Programming**
Almost everything we see in a Windows application is itself a window. That includes not only the usual "windows" in which applications such as Windows Explorer or Manifold run, but also all the various command buttons, toolbar buttons, dialogs, menu bars and other items one sees on screen. A "window" is just a rectangular region. Each window in Microsoft Windows is assigned a unique id number called the window handle or hWnd.

The operating system continuously surveys each window for any activity. Different types of activity, such as a mouse click or the window being uncovered by another window is an event. When the operating system sees an event occur, it sends a message to all windows, broadcasting news of the event to literally all of the windows. Each window then decides what to do with that message by consulting whatever instructions it has on hand for handling messages of that sort. For example, a window can repaint itself if it has been exposed by another window. Most messages are handled for us automatically by the Windows operating system so we rarely need to think about low-level housekeeping details. Higher level messages are exposed as event procedures that we can utilize as we see fit.

Event-Driven Programming

Traditional, "procedural" languages like the original BASIC language are conceptually quite simple: the program begins at the first line of code and then steps through all the other lines of code in order, making departures from time to time to visit procedural subroutines or to follow loops.

Event-driven programming is quite different, since any part of the code might be called at any time when an event that triggers it occurs. We have to write our code so that any assumptions we make we know will be true at all times. For example, we should keep an "OK" command button disabled if it requires user entry of text into an edit box until we know the edit box actually contains text. Since programs as well as humans can write text into a text box (and thus trigger an event), we have to keep in mind that things may change without human user intervention. This model requires some more thought but it is wonderfully flexible and often results in far more reusable and adaptable code than traditional procedural code.

Forms-Based Programming

Traditional languages involve development along a typical path consisting of three steps: writing the code, compiling it, and then running it. We iterate through this path over and over when creating an application. Creating the user interface in traditional applications is an interwoven part of writing the code and at times will result in spaghetti code connections between various parts of the program to service different user interface situations.

Because everything in Windows programming revolves around windows, events and messages, we take a different approach in most Windows programming and use Forms-Based programming. This involves three steps:

- Create the user interface (a form).
- Set properties for the controls used in the form.
- Write code within a script that implements program logic and tells the controls what to do.

Forms are used to create the windows used to interface to your script or application. They are also used to view tables and otherwise interact with databases through a forms-based human interface. In Manifold, we use the File - Create - Form menu command to create a new form. We can then pop open that form and add controls to it from the Tools toolbar, from the Tools (Advanced) toolbar or from other sources.

Next, we set the properties for each item in the form if we would like to change them from the defaults. This lets us take advantage of the very rich set of automated user interface capabilities Windows provides to control appearance and behavior and otherwise deal with events.

For example, instead of showing a command button as a simple 3D button with a caption we can show it as button with an image on it. We can even use different images in the up and down position, if desired. If we like, in about three seconds we can change the button's properties so that whenever the mouse cursor passes over it the cursor will change to a custom graphic. Cool!

Finally, we open the script associated with the form and write the code that powers the form in VBScript using classic ActiveX, Visual Basic and Windows ideas such as objects, object properties, and object methods. The discipline of having a form that keeps our controls and their properties well organized is a great help in keeping our code clearly organized.
The above sequence of three steps in forms-based programming is typical of Visual Basic application development within Visual Studio. The magic of Manifold System is that the above methodology also may be used with VBScript within Manifold scripts as well. This allows rapid development of sophisticated scripts that provide first-rate user interfaces created in a point-and-click manner.

**ActiveX Languages**

Scripting within Manifold is implemented using either .NET languages or ActiveX scripting. This means that you can use any language for scripting within Manifold for which an ActiveX scripting engine is installed on your computer. For the present, VBScript and JScript are installed with Internet Explorer, a required prerequisite for running Manifold.

At the present writing, downloadable, free-of-charge ActiveX scripting engines for PERL and Python are available from sources such as [www.activestate.com](http://www.activestate.com). End users may download these engines, install them and then merrily write Manifold scripts in either PERL or Python. Manifold.net personnel have experimentally used PERL and Python enthusiastically with both languages on a casual basis.

Other scripting languages, such as REXX and Tcl/Tk, are said to be available as ActiveX scripting engines and presumably could be used within Manifold. These have not been used at Manifold.net but we would be interested in hearing from users who have experimented with them or with any other scripting languages within Manifold.

The practical limitations of development and technical support mean that Manifold's form based programming facilities are designed for VBScript. Users of other languages should not expect to be able to use Manifold's forms and drag and drop controls with those languages. If you work with those other languages you should plan on scripting within the ordinary, text-based facilities of that language. Nonetheless scripts of immense power can be created using languages other than VBScript. We think it's neat that Manifold users can choose the scripting language they like best for the task at hand.

**Choosing a Scripting Language**

To specify a language other than VBScript, open a script for editing in a script window and then choose Script - Language. This dialog allows choice of which scripting language is used. Any scripting language installed in your Windows system may be used. Examples in this documentation are provided for VBScript, JScript, ActivePython, and ActivePERL (the latter two languages from [www.activestate.com](http://www.activestate.com)). Overall, we suggest use of VBScript, JScript, C#, JScript .NET or Visual Basic .NET.

Although .NET languages like C# can have a slightly steeper learning curve for total beginners than ActiveX scripting languages like VBScript or JScript, it is clear that more and more people, even beginners, are writing their Manifold scripts in .NET languages.

**A Future for VBA Enthusiasts**

Avid VBA users may rise to the defense of VBA and may complain this topic overstates the case against VBA. It's true that VBA is a beloved first introduction to VB for many people who are transitioning from casual macro creation and application configuration into serious, professional programming. For that, one should be grateful for VBA, but one's gratitude should not cloud one's eyes into not seeing the many disadvantages of VBA compared to real VB, VB .NET or VBScript.

If you have spent years working with VBA, be happy that you have invested time and effort into developing expertise that is readily portable into VB, VB .NET and VBScript. If you like VBA you'll love working in VB .NET in Visual Studio .NET and you'll feel right at home snapping out sparkling web stuff and Manifold scripts in VBScript.

**.NET and Version Skew**

Manifold utilizes Microsoft's .NET Framework which is being actively evolved for everyone's benefit by Microsoft. Developers should therefore take care to pay attention to what versions of the .NET Framework and their development tools are in use.

For example, Visual Studio .NET 2003 only supports .NET 1.1 assemblies, not .NET 2.0 assemblies. Manifold 6.50 used .NET 1.1 and so could be used with Visual Studio .NET 2003. In contrast, however, Manifold 6.50 SP1 uses .NET 2.0 and so requires Visual Studio .NET 2005 or later.
If we do not yet have Visual Studio .NET 2005, we can download various Express editions of it for free from the Microsoft web site.

**Scripting the User Interface**

Manifold scripts can control user interface elements such as dialogs. A script that controls the user interface must run in a separate thread, which can be arranged via the Properties context menu that pops up when we right click on a script in the project pane and choose Properties. This menu allows us to check the Run in separate thread property. Running a script in a separate thread allows using advanced scripting techniques such as scripting the user interface, but might be slightly slower in some cases. By default, the option is turned off. See the User Interface Scripting topic.

**Notes**

Visual Basic .NET is often abbreviated "VB .NET" within Manifold dialogs, apparently inserting an extra space between the "VB" and the " .NET." This usage follows the most common Microsoft practise. However, Microsoft is so large that there is not a totally uniform usage within the company and some Microsoft publications will use "VB .NET", "VB.Net" and even "VB NET." This documentation tends to use VB .NET.

Within Manifold, all .NET assemblies (including Manifold.Interop) are installed into the global assembly cache to facilitate reuse.

**Internet Resources**

Visit the Manifold website at http://www.manifold.net and drill down into the Free Stuff page for links to scripting and programming examples.

Visit the Support page on the Manifold website to find links to the latest Manifold User Group forums in which scripting and programming are discussed. It is extremely important to tap into the collective experience of the Manifold user community when first learning to program Manifold System. Seeing examples and reading discussion on programming is a very important part of learning.

The easiest forum to access is the Georeference forum originally started by the Manifold System User Group and now run by the Manifold online community. Click on the Community page at the manifold.net home page or simply visit http://forum.manifold.net - Thousands of Manifold users from all over the world meet at that forum to discuss Manifold System, programming, IMS and related topics.

Developing Applications

Manifold applications may be developed using a variety of approaches, from simple scripts within Manifold, to code that functions as add-ins within Manifold, to standalone applications utilizing Manifold through the object model, to web applications. See the Programming Manifold topic for an introduction to the range of possibilities.

This topic provides some supplemental notes for programmers creating external applications which utilize Manifold through the object model, via COM or .NET.

Licensing

Every machine than runs Manifold or any part of Manifold must have a Manifold license. A purely external application that utilizes Manifold only through the object model needs only a Manifold runtime license. At the present writing there are two Manifold runtime licenses available:

- **Professional Runtime x64** - This license provides access to most Manifold API features and is used for applications that do not need Enterprise Edition features or features in Manifold extension options.
- **Universal Runtime x64** - This license provides access to all Manifold API features including Enterprise Edition, Business Tools, Geocoding Tools and Surface Tools features. It is used in cases where Enterprise features such as access to a spatial DBMS like Oracle Spatial are required or when some specific feature within an extension is required.

Note that an x64 license will run in 32-bit Windows as well as 64-bit Windows. See the 32-bit and 64-bit Manifold Editions topic for a discussion of 32-bit and 64-bit licenses and issues.

Volume discounts are available for runtime licenses. See the manifold.net website for the volume discount price schedule. See the Advice for Applications Developers section in the Programming Manifold topic for a discussion of serial number and activation issues of interest to developers.

Learning and Support

Microsoft Visual Studio is the most common development tool used for developing applications that utilize the Manifold API. Visual Studio is used to create Manifold itself and is the only development environment supported by Manifold Technical Support when processing developer support incidents. It is therefore wise for programmers who wish to have maximum support resources from manifold.net and from other programmers in the Manifold user community to utilize Visual Studio as well. Visual Studio Express editions are available for free download from Microsoft.

General tips for programmers developing their first applications using the Manifold API:

- **Gain proficiency with Visual Studio** - Programming a sophisticated, complex and extensive API like Manifold is not a project for beginners. The better your programming skills are in general and the greater your expertise with Visual Studio, the smoother your projects with Manifold will go.
- **Master accessory technologies** - Many applications will involve other software: web applications, for example, will require the usual web development skills such as precise familiarity with IIS, administrative and security expertise and so forth. Almost all sophisticated web applications and many standalone applications will utilize a DBMS. Solid mastery of such accessory technologies will help avoid confusion while learning Manifold.
- **Learn Manifold as an interactive application** - Manifold is an immense application with numerous controls that help manage the intrinsic sophistication and complexity of GIS. If you don't learn Manifold interactively you won't have the conceptual and practical foundation to use the API effectively.
- **Study documentation** - Information of interest to programmers will often be found in the documentation within topics aimed at interactive users as well as within the programming reference.
- **Study examples** - Carefully study all examples published on the manifold.net web site, in the documentation, on other sites and in the forum.
- **Use the forum** - Become a master at using the GeoReference forum, at http://forum.manifold.net as of this writing. Follow threads, learn to search deep into the forum, study examples and contribute to discussions on Manifold programming in the forum.
- **Leverage tech support** - Read the Technical Support topic and the Support page on the manifold.net web site. Programmers who have mastered Visual Studio, who have learned Manifold interactively, who read documentation and study examples effectively and who participate in the forum
will usually never seek technical support. Nonetheless, should you need to use a developer technical support incident it is important to use that incident effectively.

The above assumes that programmers have a basic foundation in those GIS concepts they will need that cannot be learned through Manifold documentation. If a programming project involves sophisticated manipulation of projections, for example, it could be that the developer will need some supplemental education through distance learning, use of a consultant or attendance at a local university course.

**Updates and New Releases**

Manifold frequently issues routine updates to existing releases and every year or so issues a major new release. Programmers upgrading either to an update or to a new release should carefully study the release notes for the update or new release, as small changes (or major changes) may require rewriting of code for compatibility.

In general, upgrading between major versions of Manifold, for example, from Release 7x to Release 8, requires a recompilation but upgrading within routine updates, such as any updates published for Release 8, does not.

Following are step-by-step examples of using Visual Studio to upgrade applications in typical scenarios involving a new Manifold release:

**Upgrading a console application or class library written in C#, that only uses Manifold.Interop.dll:**

1. Launch Visual Studio, open the project, open the Solution Explorer pane, open the References node for the project,
2. Remove the reference for Manifold (right-click the reference and select Remove),
3. Right-click the References node, select Add Reference, switch to the COM tab, select Manifold System Type Library, click OK,
4. Rebuild.

**Upgrading a Windows application written in C#, that uses the Manifold ActiveX control:**

1. Remove both the bin and obj folders
2. Launch Visual Studio, open the project, open the Solution Explorer pane, open the References node for the project,
3. Remove the references for AxManifold and Manifold,
4. Right-click the project node, select Add - Windows Form, click Add, open the Toolbox pane,
5. Drop any old items for the Manifold ActiveX control you might have,
6. Add an item for the currently installed version of the Manifold ActiveX control (right-click the empty area in the toolbox, select Choose Items, switch to the COM Components tab, check Manifold MapControl Object, click OK),
7. Drop the item for the Manifold ActiveX control onto the form (to re-generate the dropped references),
8. Switch to the Solution Explorer pane, remove the new form,
9. Rebuild.

**Upgrading a console application or class library written in VB.NET, that only uses Manifold.Interop.dll:**

1. Launch Visual Studio, open the project, open the Solution Explorer pane, double click the My Project node,
2. Switch to the References tab, remove the reference for Manifold,
3. Click Add and select Reference, switch to the COM tab, select Manifold System Type Library, click OK,
4. Rebuild.

**Upgrading a Windows application written in VB.NET, that uses the Manifold ActiveX control:**

1. Remove both the bin and obj folders,
2. Launch Visual Studio, open the project, open the Solution Explorer pane, double click the My Project node, switch to the References tab,
3. Remove the references for AxManifold and Manifold (which will turn blank after you remove AxManifold - that's OK).

4. Right-click the project node, select Add - Windows Form, click Add, open the Toolbox pane, drop any old items for the Manifold ActiveX control you might have,

5. Add an item for the currently installed version of the Manifold ActiveX control,

6. Drop the item for the Manifold ActiveX control onto the form,

7. Switch to the Solution Explorer pane, remove the new form,

8. Rebuild.

Many of the mechanical details of creating and maintaining applications are specific to the choice of a particular development environment such as Visual Studio, as can be seen in the examples above. Programmers are therefore strongly encouraged to use Visual Studio to get the benefit of as many support and informational resources as possible.

Programming Manifold

Scripts

Scripts are Manifold programs written in an ActiveX or .NET programming language that is installed on the computer system.

Visual Basic Scripting Edition is the default ActiveX scripting language used with Manifold; however, JScript (Microsoft's implementation of Javascript) is also frequently used. Scripts may be written in any language for which an ActiveX scripting engine is available. Some users, for example, prefer to write scripts in Python or Perl using ActiveX scripting engines for those languages that are available from third party suppliers.

Documentation and technical support for scripting in Manifold uses VBScript with occasional examples in JScript. The use of other languages is respected but is not covered by documentation or technical support. VBScript and JScript are covered since these are standard Microsoft languages that may be redistributed by manifold.net with Manifold.

Manifold also supports scripting in Microsoft .NET languages such as C#, JScript .NET, IronPython .NET and VB .NET.

Scripts are components that appear in the project pane.

- To create a script, choose File - Create - Script or using the Create button in the project pane toolbar, choose Script.
- Double click a script component to edit it in a script window. Specify the language to be used with Scripts - Language.
- Highlight a script in the project pane and press the Run button to execute it.

When a script window is open, the Script menu is available:

- Open Form
  Open the form associated with this script.

- Open Table
  Open the table associated with this script.

- Run
  Run the script

- Run under Debugger
  Run a script under control of the debugger. Available if the Debugger is installed.

- Pause
  Pause execution of a script. Available if the Debugger is installed.

- Stop
  Stop execution of a script. Available if the Debugger is installed.
Step Into  Step over a routine. Available if the Debugger is installed.

Step Out  Step into a routine. Available if the Debugger is installed.

Step Over  Step out of a routine. Available if the Debugger is installed.

Language  Specify a scripting language. Available choices will include all supported ActiveX scripting engines installed on the computer system as well as all supported .NET scripting languages.

References  View and modify script references. Available for .NET scripts.

Compile to DLL  Compile a script into a DLL. Available for .NET scripts.

Note: In the above comments, "Available if the Debugger is installed" means the capability is available if an ActiveX language is being used and the necessary Microsoft facilities to enable the Manifold debugger have been installed. See the Debugger topic.

Use keyboard shortcuts to set and clear breakpoints. Click on a text line in the script window and then press F9 to toggle a breakpoint at that line.

Example

Choose File - Create - Script to create a new script component in the project pane.

The Create Script dialog box will allow us to name our new script, provide an optional description and choose a language (default choices being C#, JScript, JScript.NET, VB.NET and VBScript). If a .NET language is selected, we can check the Add references for standard .NET modules box. Regardless of whether or not you check this box, you can always add new references or remove existing references using the Script - References command.

The new script component will appear in the project pane marked with a script icon. Clicking on the component to highlight it will provide information about script in the project pane status bar, including the size of the script and the language used.

Double-click the script component to open it in a script window. The new script will appear with startup text appropriate for that language, by default showing a simple script to print "Hello, World!" to a message box.

Running a Script
Creating a new script automatically loads it with code for the language of choice to display the classic "Hello, World!" message in a message box. This helps us get started by providing a framework and is extremely useful when writing applications that say "Hello."

Suppose we have created a VB .NET script. The default text in the script will be:

```
Imports Manifold.Interop.Scripts

Class Script
    Shared Sub Main
        Context.Application.MessageBox("Hello, World!", "Script")
    End Sub
End Class
```

Note that the above script uses the built-in Application object.

Press the Run button in the Tools toolbar to run the script. We can also click onto the script component in the project pane to highlight it and then press the Run button in the project pane.

A message box appears with our desired message. Press OK to close the message box.

If we had used a .NET language like VB .NET, whenever we run the script it will first be compiled, which may add a delay before the script launches in the case of large scripts. We can avoid this delay by using the Script - Compile to DLL command to compile the script into a DLL.

Any errors detected during compilation of a .NET script will be displayed in the Errors pane.

Note: If we are working in an ActiveX language and the Debugger has been configured we can run scripts using the Debugger. See the Debugger topic for more information.

**Command Line Script Startup**

The `autoexec:<scriptname>` command line switch allows running a script after opening the MAP file specified in the same command line. For example, the following command line will open the `mymap.map` project file and then run the `myscript` script found in that project file.

```
manifold.exe /autoexec:myscript c:\MyProjects\mymap.map
```

**Saying Hello in C#**

The C# version of "Hello, World" is:
using Manifold.Interop.Scripts;

class Script {
    static void Main()
    {
        Context.Application.MessageBox("Hello, World!", "Script");
    }
}

Saying Hello in JScript

The JScript version of "Hello, World" is:

function Main()
    {
        Application.MessageBox("Hello, World!", "Script");
    }

Saying Hello in JScript .NET

The JScript .NET version of "Hello, World" is:

import Manifold.Interop.Scripts.*;

class Script {
    static void Main()
    {
        Context.get_Application().MessageBox("Hello, World!", "Script");
    }
}

Saying Hello in VB .NET

The VB .NET version of "Hello, World" is:

Imports Manifold.Interop.Scripts

Class Script
    Shared Sub Main
        Context.Application.MessageBox("Hello, World!", "Script")
    End Sub
End Class

Saying Hello in VBScript

The VBScript version of "Hello, World" is:

Sub Main
    Application.MessageBox "Hello, World!", "Script"
End Sub

Saying Hello in IronPython
IronPython is the fine .NET language created by Jim Hugunin and supported by Microsoft. It has emerged as the Python of choice for Microsoft .NET and is supported by Manifold Technical Support for developer level support incident questions.

```python

def Main():
    Application.MessageBox("Hello, World!", "Script")

Main();
```

The above example consists of four lines of code, the third line of which is blank. Whitespace is significant in Python so it is important that the third line remain blank for the example to function.

IronPython scripts intended to be used for active columns should only include the body for a single script function.

Creating a script in IronPython automatically adds references to the IronPython assemblies. To work correctly in all cases, the IronPython assemblies should be installed in the Global Assembly Cache. The Global Assembly Cache (GAC) is a central place for .NET assemblies on a machine. Putting an assembly into the GAC makes it possible for all .NET applications to locate and use that assembly.

To put IronPython assemblies into the GAC, open the Command Prompt as a user with administrative privileges (use Run As Administrator in Windows Vista), navigate to the IronPython folder, and run the following commands:

```cmd
    gacutil -i ironpython.dll
    gacutil -i ironmath.dll
```

The above requires installation of the .NET SDK (which contains the GACUTIL program). The .NET SDK is easily found and downloaded from the Microsoft web site.

Thanks go out to Jim Hugunin for creating IronPython (excellent name!) and also to Microsoft for supporting IronPython. Well done!

**Saying Hello in PythonScript and PerlScript**

Many languages are available as ActiveX scripting languages for Windows. For example, installing the Active State Python or Perl distributions (free as of this writing from http://www.activestate.com) will add Python and Perl scripting capabilities to Manifold. As with JScript, scripts in these languages use the built-in Application object.

**PythonScript:**

```python
def Main():
    Application.MessageBox("Hello, World!"

Main();
```

**PerlScript:**

```perl
sub Main {
    $Application->MessageBox("Hello, World!");
}
```

Some users prefer scripting in Python or Perl to scripting in VBScript or JScript; however, Manifold technical support is able to support only VBScript, JScript and the .NET languages.

**Adding Scripts as Toolbar Buttons or Menu Commands**

Scripts (which may call external COM objects) may be added as custom toolbar buttons or menu items. See the Add-Ins topic for information on adding new toolbar buttons or menu commands.

**Script Window Keyboard Shortcuts**
Script windows support well-known Windows keyboard shortcuts, including those often used in Windows programming editors:

- **CTRL-A** Select All
- **CTRL-X** Cut selected text and copy to the Clipboard.
- **CTRL-C** Copy selected text to the Clipboard.
- **CTRL-V** Paste text contents of the Clipboard.
- **CTRL-L** Delete current line.
- **CTRL-K** Comment out selected text.
- **SHIFT-CTRL-K** Uncomment selected text.
- **CTRL-M** Convert selected text to lower case.
- **SHIFT-CTRL-M** Convert selected text to upper case.
- **CTRL-Insert** Equivalent to **CTRL-C**. An old Windows shortcut kept for compatibility.
- **SHIFT-Insert** Equivalent to **CTRL-V**. An old Windows shortcut kept for compatibility.
- **CTRL-Z** Multi-level Undo.
- **CTRL-Y** Multi-level Redo.
- **CTRL-[]** Check the character near the cursor and, if it is a bracket character, jump to the matching bracket.
- **CTRL-SHIFT-[]** Check the character near the cursor and, if it is a bracket character select the text between the bracket and the matching bracket.
- **SHIFT-Delete** Same as **CTRL-X** or Cut.
- **ALT-Backspace** Same as **CTRL-Z** or multi-level Undo.

**CTRL-K** and **SHIFT-CTRL-K** comment/uncomment commands will automatically switch between commenting styles based on the language specified for the script window with the Script - Language command. Works for C#, JScript, JScript .NET, PERL, Python, VBScript and VB .NET.

Recognized bracket combinations for use with **Ctrl-[]** and **Ctrl-SHIFT-[]** are { and }, [ and ], ' and '”, and # and # (used to delimit dates in queries).

**Example: Referencing a Script that has been Compiled into a DLL**

The Script - Compile to DLL command may be used with .NET languages to avoid the slight compile delay when the .NET script is compiled before running. The command may also be used to compile .NET language scripts into DLLs for future use in other scripts, as in the following example:

1. Launch Manifold. Create a new project.

2. Create a new script using VB .NET. Enter the following script text:

```vbnet
Imports Manifold.Interop
Public Class Test
    Public Shared Function ComponentCount(D As Document) As String
```

Public Class Test
    Public Shared Function ComponentCount(D As Document) As String
Return D.ComponentSet.Count
End Function
End Class

3. Choose Script - Compile to DLL and save the DLL into the Manifold installation folder (that is, the Windows folder into which Manifold System itself was installed, by default, C:\Program Files\Manifold System).

4. Create another script using VB .NET. Invoke Script - References. Click New, and select the compiled DLL created in the above steps. Enter the following script text:

Imports Manifold.Interop.Scripts

Class Script
    Shared Sub Main
        Context.Application.MessageBox( _
        Test.ComponentCount( _
        Context.Application.ActiveDocument), "Script")
    End Sub
End Class

Invoke Script - Run. The script will show the number of components in the currently opened MAP file.

It is, of course, possible to place a compiled DLL into a folder that is different from the Manifold installation folder, but then we would have to make sure the .NET loader will be able to find both:

a) the compiled DLL when running a Manifold script that refers to it (usually achieved by either signing the compiled DLL and putting it into the global assembly cache, or by putting the compiled DLL into a folder mentioned in the PATH environment variable), and

b) all Manifold DLLs required when loading the compiled DLL (usually achieved by using a custom configuration file).

Running a .NET script first searches for referenced assemblies that use relative paths in the Manifold installation folder and then searches in the Configuration folder set in Tools - Options in File Locations.

See Microsoft documentation on .NET languages for details, including MSDN. In particular see this MSDN topic (URL current as of the time of writing) for more information:

Notes

Attempting to save or close a project in the middle of an executing script will display a warning message. Stop any executing scripts before saving or closing a project.

Script windows support multi-level Undo / Redo. One can CTRL-Z (Undo) backwards through many changes and CTRL-Y (Redo) forwards to redo many Undo operations.

Script windows will show their contents using different colored font for different parts of the script. This is called syntax highlighting and is a helpful way of identifying typographical errors. Fonts used in script windows may be specified in Tools - Options. However, fonts used with script windows will be restricted to fixed-width fonts.

Add-Ins
Script Examples
See the Active Columns topic for a cool use of scripts within tables. See Active Columns using VBScript and Active Columns using JScript for examples using active columns and script functions written in VBScript and JScript.

See the Forms and Scripts topic for examples of using scripts together with forms.

See the Debugger topic if you are working with ActiveX languages and interested in using the Debugger.
Click Events
Manifold scripts may be written for processing of mouse clicks and double clicks done in drawing, image, labels, map, profile, surface, or theme windows. Click events are routed to a script or form named OnClick. Double click events are routed to a script or form named OnDoubleClick. The parameters of both events are delivered through the global EventArgs object.

The Process global events with scripts option in Tools - Options - Miscellaneous allows (the default) or disallows the processing of click and double click events with scripts.

If desired, the OnDoubleClick event handler can cancel further processing of a clicked object (which might otherwise go to an URL or result in the display of the Object Fields dialog) by setting the Handled property of the EventArgs object to True.

Example
Create a VBScript script named OnClick and enter the following script:

```vbscript
Sub Main
    If EventArgs.HasObject Then
        Application.MessageBox EventArgs.Object.ID, "Clicked Object"
    End If
End Sub
```
Create a new drawing and populate it with some objects. Click an object. The system will display a message box reporting the object's ID.

EventArgs Object
Tools - Options
Update Batching

The BatchUpdate property of a Document object turns batch update mode on and off. The Document object manages components and document-wide properties. Batch update mode controls how changes made by a script are propagated to the mapfile.

When BatchUpdate is off (the default), any changes made in the script are immediately propagated to the mapfile. This is convenient for many purposes and assures that script objects always report fresh information. However, at times making a update on every change will hurt performance. For example, when selecting pixels in a surface or image one loops through program logic that sets the pixel mask for each pixel. Propagating each change would mean a refresh of the entire display for each pixel. It would be best in such cases to turn BatchUpdate on, run the selection logic, and then turn BatchUpdate off.

When batch mode is on, changes made by a script are not immediately propagated to the mapfile. This is faster but can make script objects report outdated information. The recommended technique is to turn BatchUpdates on when bulk changes are being made to data and to then turn it back off when all necessary changes have been done. This is especially important with operations on images and surfaces, but also makes sense for selection operations with objects in drawings.

Example

Suppose we are working with pixels in a surface. We will select or deselect each pixel based on some criterion. The following VBScript script fragment shows use of BatchUpdate with some lines boldfaced for emphasis:

```
Sub Main
    Set app = Application

    ' -- locate opened window and ensure it displays surface
    Set window = app.WindowSet.ActiveWindow
    Set component = window.Component
    If window.Component.Type <> ComponentSurface Then
        MsgBox "No surface."
        Exit Sub
    End If

    Set surface = window.Component
    Set pixels = surface.PixelSet

    ' -- miscellaneous program logic goes here

    ' -- turn batch updates on
    app.ActiveDocument.BatchUpdates = True

    ' -- select pixels
    For i = 0 To pixels.Count-1
        ' -- pixel selection logic goes here, for example,
        ' -- pixel.Mask = pixel.Mask Or 1 to select and
        ' -- pixel.Mask = pixel.Mask And Not 1 to deselect.
        Next

    ' -- turn batch updates off
    app.ActiveDocument.BatchUpdates = False

End Sub
```

Note that all program logic except the bulk selection process done in a loop is done with BatchUpdates turned off. Only the pixel-by-pixel selection loop has BatchUpdates turned on.

User Interface Scripting

Manifold supports scripting of user interface elements such as dialogs and controls. User interface scripting is available for regular scripts and forms, but is unavailable for active columns, where it would be impractical for performance reasons, external applications and web sites using Manifold objects (where there is no Manifold user interface present).

Scripting of the user interface allows running interactive commands and controlling dialogs and controls, with scripting supported for common Windows controls such as buttons, check boxes, labels, text boxes, list boxes, combo boxes, tree views and list views. User interface scripting objects support scripting of the progress bar and slider controls, via the Text property. All Manifold dialogs support user interface scripting.

Scripts that operate with user interface elements must be run in a thread separate from the user interface thread. This can be arranged via the Properties context menu that pops up when we right click on a script in the project pane and choose Properties. This menu allows us to check the Run in separate thread property. Running a script in a separate thread allows using advanced scripting techniques such as scripting the user interface, but might be slightly slower in some cases. By default, the option is turned off so this property must be explicitly set to enable user interface scripting.

Form scripts can be configured to run in a separate thread, which allows scripting the user interface. Running a script from another script spawns a new thread, in case the callee is configured to run in a separate thread. This allows freely mixing scripts that are configured to run in the calling thread or a new thread.

User interface scripting objects support numerous Manifold facilities, including:

- Scripting panes in the main window as well as scripting toolbar controls. Each toolbar button is interpreted as a separate user interface control.
- Scripting combo boxes, text boxes and other non-button controls in toolbars.
- Support for "pushing" buttons in the drop-down portions of color, size, and style wells, such as buttons for invoking the thematic formatting dialog, and similar windows.
- Support for scripting format lists such as the list of colors in the Display Options dialog for surfaces.
- Invoking a user interface command within a script allows specifying the command context to access commands available in the various context menus and in panes.
- User interface scripting objects support reading and writing values of items in list view controls, such as the list view in the contouring dialog.

User interface scripting objects also support scripting non-Manifold dialogs, such as the open file dialog. Names of controls for non-Manifold dialogs are synthesized on the fly.

Example - Spatial Overlays

Suppose we have a map component called Map that includes a drawing of areas named States and a drawing of points named Cities. The drawings share some common columns. We can script a spatial overlay with the following:

Sub Main
    Document.ComponentSet("Map").Open
    Set ui = Application.UserInterface
    ui.InvokeCommand "MapSpatialOverlay"
    Set dlg = ui.ModalDialog
    dlg.ControlSet("ComboBoxSource").Text = "[All Objects in States]"
    dlg.ControlSet("ComboBoxTarget").Text = "[All Objects in Cities]"
    dlg.ControlSet("ComboBoxMethod").Text = "Areas to contained points"
    dlg.Accept
End Sub

Discovering Control Names
It’s easy to discover the names assigned to various controls in Manifold dialogs. Right clicking the caption of a dialog or undocked pane or toolbar and choosing List Controls from the context menu will display a list of programmatic names of dialog or pane controls or toolbar commands that may be used with user interface scripting.

Another choice is to use the /clist command line option, which dumps the names of all commands available for user interface scripting using the InvokeCommand method of the UserInterface object into a text file.

Example - Discover Control Names in the Dissolve Dialog

If we open a drawing and then choose Drawing - Dissolve we open the Dissolve dialog.

Right clicking on the caption for the dialog...

...and then choosing List Controls from the context menu...
Programming

...will display the Controls list of the names of controls available for programmatic use.
Tech Tip
Attempting to locate a pane using its name within a script allows omitting the component name postfix. For
example, attempting to locate a pane named Control Points will succeed even if there is an active component,
which sets the pane name to Control Points - [Component Name].

Scripts

Script Examples

Script Examples
See the Manifold web site for scripting examples that may be published from time to time in addition to those
below.
.NET Language Examples
Manifold may be programmed in .NET languages such as VB .NET or C#. Some elementary examples follow.
Example
Display all drawings found in the active project using VB .NET:
Imports Manifold.Interop
Imports Manifold.Interop.Scripts
Imports Microsoft.VisualBasic
Class Script
Shared Sub Main
Dim doc As Document = Context.Application.ActiveDocument
Dim cmp As Component
Dim rpt As String = ""

2393


' traverse all components and add name of each drawing to
' report
For Each cmp In doc.ComponentSet
    If cmp.Type = ComponentType.ComponentDrawing Then
        If rpt <> "" Then
            rpt = rpt & vbCrLf
        End If
        rpt = rpt & cmp.Name
    End If
Next

' check if there are no drawings
If rpt = "" Then
    rpt = "No drawings."
End If

Context.Application.MessageBox(rpt, "Script")
End Sub
End Class

Example

Do the same using C#:

using System;
using Manifold.Interop;
using Manifold.Interop.Scripts;
class Script {
    static void Main() {
        String rpt = "";

        // traverse all components and add name of each drawing to
        // report
        foreach (Component cmp in doc.ComponentSet) {
            if (cmp.Type == ComponentType.ComponentDrawing) {
                if (rpt != "")
                    rpt = rpt + "\n";
                rpt = rpt + cmp.Name;
            }
        }

        // check if there are no drawings
        if (rpt == "")
            rpt = "No drawings."

        Context.Application.MessageBox(rpt, "Script");
    }
}

Example
Create a new drawing and populate it with a point object using VB .NET:

Imports Manifold.Interop
Imports Manifold.Interop.Scripts

Class Script
    Shared Sub Main
        Dim app As Application = Context.Application
        Dim doc As Document = app.ActiveDocument

        ' create new drawing
        Dim drw As Drawing = doc.NewDrawing("New Drawing")

        ' create new point and then new object
        Dim pnt As Point = app.NewPoint(10, 20)
        Dim pntGeom As Geom = app.NewGeom(GeomType.GeomPoint, pnt)
        drw.ObjectSet.Add(pntGeom)

        ' open created drawing
        drw.Open
    End Sub
End Class

See Also

See the manifold.net web site for additional scripting examples.

Forms

Forms are Windows dialogs created within Manifold that provide customized user interfaces to scripts, queries, tables and other items. Forms are themselves programming object that have properties and methods and can react to events. When a form is created, a script for that form is automatically created as well. The scripting code written in the script specifies the program logic that is used with the controls on the form.

For example, a script that showed the positions of trucks might utilize a form that included the controls shown above to allow inexperienced users to choose which class of trucks they wished to see on the map. Manifold forms can include a very wide array of controls, including toolbars, status bars, hierarchical tree diagrams, iconic data browsers, rich text panes, multimedia controls and much, much more.

Forms play the same role in Manifold scripting using Visual Basic scripting that they do in development of Visual Basic Applications within Visual Studio. In fact, almost all of the MSDN and Visual Basic documentation from Visual Studio may be used with Manifold System. Manifold's form design and form editing capabilities are similar to those of Visual Studio.

For a quick introduction to Windows programming, event-driven programming and forms-based programming, see the Programming Manifold introductory topic.
Creating a Form

1. Use the File - Create - Form command to add a form to a project. Use a template if desired.
2. Click open the form.
3. Resize the form as desired and set its Form Properties, such as the caption for its title bar.
4. Add controls from the Tools toolbar and the Tools (Advanced) toolbar.
5. Arrange controls by selecting them and using the Alignment toolbar.
6. For each control, specify its Properties.
7. Open the script associated with the form and write code to implement program logic and control behavior.

Forms may be edited using the methods described in Editing Forms. For example, controls from other forms may be dragged and dropped into a form.

Forms Context Menu

Right click onto any unused part of a form to call up the context menu for forms. Right clicking onto a control in a form will call up the context menu for that control.

- **Size to Fit**  
  Resize the form so it just encloses the controls that are in it.

- **Test**  
  Execute the form for placement of controls. This is not a full test of the script and only provides a visual preview. Use Alt-F4 to close the form if it is not equipped with a Control Box "close" button in the upper right corner.

- **Properties**  
  See and set the form's properties.

Tech Tips

Forms may be copied and pasted. Forms may also be imported from other .map files using the File - Import - Component command. This allows us to save collections of frequently used forms in a .map file from which a desired form may be imported when needed.

Although forms cannot be shared on an Enterprise server if Enterprise Edition is being used, there is an alternative way of creating reusable forms using .NET scripts: The Script - References dialog is available whenever a script window using a .NET language as the Script - Language is opened. The dialog allows specification of external .NET modules to which the script may refer. For example, one can refer to System.Windows.Forms.dll and have a script display a form. The resulting script can then be shared on an Enterprise server and reused in other projects.

Form Properties

Forms are Windows dialogs created within Manifold that provide customized user interfaces to scripts, queries, tables and other items. Forms are themselves programming objects that have properties and methods and can react to events. See the Programming Manifold topic for an introduction to programming and the Forms topic for a brief introduction to forms.

Form Properties

Right click onto a form (except directly onto a control) and choose Properties from the context menu to see and set the form’s properties:

- **Caption**: The text string for the title bar.
- **Tag**: A string available for free use by the programmer. Often used for comments.
- **Control Box**: Check the Control Box to create the X “close” box in the upper right corner of the form and to enable creation of Minimize and Maximize boxes. If checked, will add to the title bar a standard Windows right mouse context menu with Restore, Move, Size, Minimize, Maximize and Close (ALT+F4) choices.
  
  **Note**: if you create a form with no Control Box there is no obvious way to close it with the mouse when it is being tested. Use ALT F4 to close it.
- **Maximize Box**: Create a maximize box control in the title bar along with the control box.
- **Minimize Box**: Create a minimize box control in the title bar along with the control box.
- **Center on Screen**: Display the form in the center of the main Manifold window.
  
  **Left**: Left margin position of the form, if Center on Screen is not checked.
  
  **Top**: Top margin position of the form, if Center on Screen is not checked.
- **Width**: Width of the form.
- **Height**: Height of the form.

**Very Important**: If you uncheck the Control Box and then use Form - Test there will be no way to close the form except by doing an ALT-F4. Even if controls (such as a "Close" command button) are added to the form to close it without having to use the X control box in the upper right corner, those controls will not be functional in "test" mode. They will only work if the form is run using the Run button from the project pane.

The form property sheet also has standard Color and Font property pages used to customize colors and font used in the form.

Form Properties Set Programmatically

Forms are created with the most frequently used defaults for properties. In addition to the above properties that are changed through the Properties dialog, several more properties may be set programmatically within the form’s script.

- **Border**: FixedSingle (default) or None. None results in an uncaptioned rectangle of background color and will also cause minimize, maximize and system menu settings to be turned off.
  
  **Note**: if you create a form with no border there is no obvious way to close it with the mouse when it is being
tested. Use **ALT F4** to close it.

**Pointer**  
The type of mouse pointer displayed when over the form. Choose from 16 different types plus a custom pointer

**Visible**  
Make this form visible or invisible.

**Enabled**  
True or False. True means the form can respond to user-generated events, false prevents it from responding. We can disable a form if we wish it to display information in a read-only way.

### Form Properties for Controls

Right click onto a control in a form and choose **Properties** from the context menu to see and set properties for the control.

Manifold adds an extra tab, the Control tab, to the usual tabs that appear in the design time properties dialog for controls. This tab provides access to the properties for this control maintained by the form. This extra tab will appear at design time for all controls. Although strictly speaking these are properties of the form that is the container for the control and not of the control, they are easiest to specify at design time if they appear within each control’s properties dialog.

**Name**  
The name used by the form to identify this control.

**Tag**  
A string available for free use by the programmer. Often used for comments.

**Visible**  
Make this control visible or invisible.

**Left**  
Left margin position of the control.

**Top**  
Top margin position of the control.

**Width**  
Width of the control.

**Height**  
Height of the control.
Form Controls

The Tools toolbar and Tools (Advanced) toolbars are used with Forms to create Windows standard user interface controls. These toolbars are enabled when a Form is the active window. Forms are used to provide user interfaces to scripts, to view tables and for other functions within Manifold.

**Very Important:** Common ActiveX controls for forms are available only for use with scripting in Manifold System running in 32-bit mode. Common ActiveX controls for forms are *not* available when Manifold is running in 64-bit mode in 64-bit Windows systems. See the 32-bit and 64-bit Manifold Editions topic when running 64-bit Manifold System editions.

To add a control to a form, click open the form and then click on the control desired. Click and drag within the form to create the control in that location at the given size. Then, right-click on the control and set its properties as desired. When controls have been created in a form they may be rearranged as desired, aligned neatly and otherwise edited as described in Editing Forms. Manifold’s built-in forms editing uses Visual Studio style mouse moves coupled with the Selection toolbar and other cool Manifold methods.

As in Visual Studio language form creation, the tab order of controls is set by default by the order in which they were created. This may be adjusted at will by right clicking and choosing move up, etc.

**Sources of Controls**

Manifold can use any ActiveX control within scripts. There are several classes of controls that have been provided by manifold.net or that may be used within Manifold.

- Frequently used controls are hosted on the Tools toolbar.
- Advanced controls are hosted on the Tools (Advanced) toolbar.
- Numerous accessory controls are provided in various .ocx collections installed by Manifold for your use.
- Manifold scripts can use controls found in any .ocx installed on your machine by other applications, for example, by Microsoft Office 2000.
- Numerous freeware and shareware ActiveX controls are available for free download via Internet.
- Many vendors sell collections of ActiveX controls for special purposes.

Manifold installs the full set of standard, redistributable controls shipped by Microsoft with Visual Studio Enterprise Edition, plus all standard, redistributable controls made available by Microsoft to its ISV partners via the Microsoft Developer Network. Users of Manifold’s Visual Basic Scripting system therefore have the same access to redistributable controls as do developers working at the highest level with these professional-quality Microsoft tools.

Manifold includes everything you need to create new programs within Manifold in Visual Basic scripting or Javascript using the above controls. There is no need to purchase Visual Studio or any extra language. Of course, if you do have Visual Studio and tools such as Visual C++ and Visual Basic you can use those as well. We highly recommend Visual Studio for professional development: it is the environment within which Manifold itself was created using Visual C++.

**Documentation for Controls**

One major advantage of using Microsoft technology is the ease with which standard controls may be included within an application such as Manifold. A major benefit to the use of standard controls is the wide availability of comprehensive reference texts devoted to Visual Basic programming using those controls. The manifold.net team has included many very sophisticated controls within Manifold for your use. These are not documented in detail, since doing justice to the power and flexibility of these controls requires a dedicated text. Programmers using these controls should have at hand one of the many excellent texts on programming in Visual Basic that covers the various controls in detail. This documentation only covers those properties (in brief) that may be set at design time via the control's Properties dialog.

To give an idea of the comprehensive power of the controls included in Manifold, we have included a summary listing of run time properties in the RichTextBox control topic together with a summary listing of this control's methods. The RichTextBox control may be used to create a full-featured, professional quality word processor within a Manifold script, if so desired. Because it is a data bound control, a more frequent use in a GIS environment might be to create elaborate forms, reports, or other richly-formatted documents that automatically load text data from a variety of external data sources.
Properties pages for some controls will feature an enabled Help button. The Help button is linked to Microsoft Help for these Microsoft controls. If you have a Microsoft programming environment and associated Help documentation (like MSDN) installed, the Help button will launch the appropriate Microsoft Help topic. If you do not have a Microsoft programming environment with Help for these standard Microsoft controls, the Help button will not be able to launch any help pages.

Frequently Used Controls

<table>
<thead>
<tr>
<th>Tool</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Insert Check Box" /></td>
<td>Insert Check Box - Inserts check box controls.</td>
</tr>
<tr>
<td><img src="image" alt="Insert Option Button" /></td>
<td>Insert Option Button - Inserts option button controls. Only one option button in a group may be selected.</td>
</tr>
<tr>
<td><img src="image" alt="Insert Command Button" /></td>
<td>Insert Command Button - Inserts command button controls.</td>
</tr>
<tr>
<td><img src="image" alt="Insert Frame" /></td>
<td>Insert Frame - Draws frame with caption. Frames are used to set off groups of controls, often option buttons.</td>
</tr>
<tr>
<td><img src="image" alt="Insert Text Box" /></td>
<td>Insert Text Box - Inserts text box. Also called an edit field or edit control. This control can display text entered by the programmer at design time or entered by the user or assigned to the control by other code at run time.</td>
</tr>
<tr>
<td><img src="image" alt="Insert Static Text Box" /></td>
<td>Insert Static Text Box - Add a customized text box.</td>
</tr>
<tr>
<td><img src="image" alt="Insert List Box" /></td>
<td>Insert List Box - Inserts list box controls.</td>
</tr>
<tr>
<td><img src="image" alt="Insert Combo Box" /></td>
<td>Insert Combo Box - Inserts combo box controls.</td>
</tr>
<tr>
<td><img src="image" alt="Insert Horizontal Scroll Bar" /></td>
<td>Insert Horizontal Scroll Bar - Inserts horizontal scroll bar controls.</td>
</tr>
<tr>
<td><img src="image" alt="Insert Vertical Scroll Bar" /></td>
<td>Insert Vertical Scroll Bar - Inserts vertical scroll bar controls.</td>
</tr>
</tbody>
</table>

Advanced Controls

<table>
<thead>
<tr>
<th>Tool</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Insert Animation" /></td>
<td>Insert Animation - Plays silent .avi files to create dialog effects like the sheet of paper that flies between folders in the Windows copy progress dialog. Can also play silent .avi files dropped onto the control. Manifold provides 19 cool Windows dialog .avi files to get started.</td>
</tr>
<tr>
<td><img src="image" alt="Insert Chart" /></td>
<td>Insert Chart - Inserts a chart control.</td>
</tr>
<tr>
<td><img src="image" alt="Insert Image List" /></td>
<td>Insert Image List - Contains a collection of images that can be used by other Windows Common Controls such as ListView, TreeView, TabStrip and Toolbar controls, as well as with other controls with a Picture property. Saves development time by maintaining all images in a</td>
</tr>
</tbody>
</table>
standard, consistent catalog of images.

Insert Image Combo Box - Similar to standard combo but with ability to include pictures with each item in the list portion of the combo, with special facilities for list management.

Insert Date / Time Picker - Displays date and/or time info and provides an interface for modifying date and time. Dropdown menu provides a MonthView calendar.

Insert Month View - An easy way to view and set date information using a monthly calendar. Can select one or multiple dates or show up to 12 months at a time.

Insert List View - Displays data as ListItem objects with an optional icon. Four different views provide data as icons, small icons, a list or a report. A sophisticated control.

Insert Progress Bar - Create a progress bar display that can be used to show the progress of a process.

Insert Masked Text Box - Used to prompt users for input using a fixed format specified by a mask pattern, for example, a telephone number in a specified format. If a mask pattern is not used, this control behaves about the same as a standard text box.

Insert Rich Text Box - Allows entry and editing of text using advanced formatting features, such as paragraph formatting with left and right indents, hanging indents, bold and italic font and so on. Also supports object embedding using the OLEObjects collection. Write your own word processor or create elaborate forms for users.

Insert Slider - Insert a slider bar control that can be moved left and right.

Insert Tree View - Insert a hierarchical tree display. Designed to display data such as organization trees, entries in an index, files and directories on disk, etc.

Insert UpDown - Insert an increment/decrement control, also called spin buttons.

Insert Tab Strip - Insert a tabbed control where clicking on each tab brings it to the fore.

Insert Picture Clip - Inserts a picture clip.

Insert Multimedia Control - Manages Media Control Interface (MCI) devices like sound boards, MIDI sequencers, CD-ROM drives, audio players, videodisc players, etc. Add voice note recording to your dialog, or play spoken announcements.

Insert Status Bar - Insert a status bar like those at the bottom of many program windows. Complete with a nearly infinite set of properties for the intrepid programmer.

Insert Tool Bar - Insert a toolbar at the top of the form that hosts buttons or other controls. Yet another control with a vast array of properties.

Insert Cool Bar - Requires installation of Internet Explorer 3.0 or greater. Provides a modern, “railbar” look and the ability to create (get this!) user configurable toolbars like
those in IE.

- **Insert Common Dialog Control** - Provides a standard set of Windows dialog boxes for opening and saving files and selecting colors and fonts. Can also display Help.

- **Insert System Info Control** - Detects system events such as desktop resizing, resolution changes, time changes. Also provides operating system platform and version information and changes in AC/battery power status and Plug/Play hardware configuration. Used when writing applications for portable devices (GIS in the field) and for developing info for your tech support team.

- **Insert ActiveX Control** - Insert any ActiveX control available on this system.

**Other Controls**

Other controls from the various .ocx files registered on the system are available for your use. These include such cool controls such as Internet controls, winsock, comm controls and other fun objects that will dazzle your users and make your competitors regret they are not using Manifold.

Use the **Insert ActiveX Control** button in the **Tools (Advanced) toolbar** to draw a rectangle in the Form where the control should be placed. A dialog will pop-up showing all controls that are registered for use on this system from which the control may be selected.
Editing Forms

Forms are edited using a combination of commands from the Forms window itself, the Alignment toolbar, the Selection toolbar and by adding controls from the Tools and Tools (Advanced) toolbars. The appearance of the form and the controls it contains are specified by setting the Form Properties of the form and the properties of the controls it contains.

![Form Window](image)

Set the size of the form at any time by resizing it within the form window.

We can change the properties of the form by right clicking on the form and choosing Properties from the context menu.

![Form Properties](image)

Change the Caption property to change the caption in the title bar.

- Control Box
- Maximize Box
- Minimize Box

Check the Control Box to create the X "close" box in the upper right corner of the form and to enable creation of Minimize and Maximize buttons. Checking the Control Box option also equips the form's title bar with a right-click context menu consisting of the standard Windows choices of Restore, Move, Size, Minimize, Maximize and Close. Click the Minimize Box and Maximize Box boxes to add these controls to the title bar.

![Form Window](image)

The result will be shown in the form window. Note the changes in the title bar.
**Very Important:** If you uncheck the Control Box and then use Form - Test there will be no way to close the form except by doing an ALT-F4. Even if controls (such as a "Close" command button) are added to the form to close it without having to use the X control box in the upper right corner, those controls will not be functional in "test" mode. They will only work if the form is run using the Run button from the project pane.

### Adding Controls

Click on any of the Tools toolbars for Form windows to choose a control. Add the control to the form by clicking and dragging where the form should appear. Standard controls when added to a form will be preconfigured with default captions and styles.

We can choose the Text Box control from the Tools toolbar.

To add this control we click and drag where we would like it to appear.

The result is a text box control with default properties. We can change those properties by right clicking on the control and choosing Properties from the resultant context menu. For example, we might wish to change the Text property of the text box from "Text" to "Sample Text".

We can also choose the Check Box control and add it to the form by clicking and dragging.
The above illustration shows the form after we have added a check box and then changed the Caption property of the check box to "A Check Box".

**Selecting Controls**

Like many things in Manifold, we will often want to select controls so that we edit them. This section is a general introduction to selecting controls using regular Manifold selection commands. Many programmers will also use "smart mouse" selection commands as discussed later on in this topic.

To save space, the subsequent illustrations will not show the Form window border or the outer border of the form. When any controls are selected the form itself is deselected and the edit handles on the form's edges will disappear. To edit (resize) the form itself, deselect the controls and the form will automatically be selected for editing.

Controls appear in the form in their unselected forms.

We can select them using any of the usual Manifold Selection mouse moves with selection modes applied as in all other uses of selection. For example, drawing a box around them with Select Box will select the two controls above. The controls will be marked with selection borders having selection handles.

Whenever a selection is made in a form one of the controls is the primary selection and all of the other selected controls are in the secondary selection. The primary selection control is the one that is used to guide actions such as alignment. This is a concept widely used in professional development tools such as Visual Studio and has proven to be very fast and intuitive. When coupled with smart mouse selection modes it allows rapid manipulation of controls in forms.

Solid black edit handles indicate the primary selected control. The primary selection is the only control that can be resized with the cursor (choose another control as the primary to resize it). The primary control guides alignment and resizing of all other selected controls within alignment and resizing commands. The most recently selected control becomes the primary selected control.
When the mouse is committed to a selection command it works in selection mode only. When we unclick the selection control toolbar button the mouse becomes available for other activities, such as resizing or moving controls. If we **unclick** the Select Box tool used earlier we will be able to use the mouse again in the Form.

For example, we can click and drag (the mouse will change to the move cursor shown above) to move a control.

We have just clicked and dragged on one control and moved both controls to the left. We can also click and drag on an edit handle in the primary control to resize it. If we click and drag on the rightmost edit handle we can resize the text box’s width.

The result is a wider text box.

Note that all Manifold selection commands will work correctly with forms. For example, the **Edit menu’s Select All, Select None and Select Inverse** commands work as expected.

As seen in the illustration above, if one control in a form is selected, using **Select Inverse** will deselect it and will select the other controls.
Keyboard TAB Key Selection

Pressing the TAB key will cycle the selection through all of the controls in the form, selecting each in turn as the primary selected object. Press the TAB key to jump the selection from one control to another. At times this is a handy way of selecting controls within a crowded form or selecting controls that lie behind other controls.

Smart Mouse Selection

Manifold form windows support "smart mouse" selection like that used in Visual Basic forms editing. If the mouse is not occupied with a command mode (such as a regular selection command like Select Box) it may be used for smart mouse selection and editing as follows:

- **Click** Click on an unselected control to select it.
- **SHIFT Click** SHIFT Click on an unselected control to add it to the selection.
- **CTRL Click** CTRL Click on a selected control to make it the primary.
- **Click and Drag** Click and drag a primary selected control to move it. Clicking and dragging a secondary selected control when more than one control is selected will move all the controls.

The best way to learn the above is to create a form with some controls and to experiment. Smart mouse selection is a fast and intuitive way of editing forms.

Moving Controls

Controls in forms may be moved using either the mouse or keyboard keys. If several controls are selected, move logic is as follows:

- Clicking and dragging on the primary selected control will move only that control.
- Clicking and dragging on any of the other (secondary selected) controls will move all of the controls.
- Arrow keys on the keyboards will reposition all selected controls one pixel at a time. Use these to "nudge" controls into position.

Arrow Key Short Cuts to Reposition and Resize

When controls are selected, arrow keys on the keyboard use the following logic:

- **Repositioning**: Arrow keys on the keyboards will reposition all selected controls one pixel at a time. Use these to "nudge" controls into position.
- **Resizing**: When only one control is selected, a SHIFT-arrow key press will resize the control. The left and right arrows will move the right margin of the control to the right or to the left. The up and down arrows will move the lower margin of the control down or up.

Using Grids and Snap to Grid

Use View - Grid to turn on a grid in the form and then use Snap to Grid to constrain the mouse cursor to moving between grid points. This greatly assists in creating controls that are reasonably aligned.
By default, forms are shown in a form window without a grid.

Choose View - Grid to launch the Grid dialog. Check the Show grid box to turn on the grid. Grids are created on a 5-pixel spacing for forms by default.

The result is that a grid of dots appears every 5 pixels within the form.

Turn on Snap to Grid by pushing the Snap to Grid button or by choosing Edit - Snap to - Grid from the main menu. When Snap to Grid is on, the mouse cursor will move only between grid points on the form. Controls may therefore be created that are shaped exactly to locations marked by grid points.
This greatly facilitates drawing grid controls that are evenly aligned. Note that the grid is displayed only on the form itself and does not appear on the controls.

**Alignment Commands**

It's often the case that one's managers, clients and other demanding users will insist on well-organized dialogs where all the controls line up neatly. These are usually the same sorts of users who complain about spelling mistakes and who expect programs to come with documentation. Fortunately for professional programmers, Manifold's forms editor provides alignment commands so we can make pretty forms without stealing too much time from downloading mp3's.

The alignment controls are found on the Alignment toolbar.

- **Align Left** - Move objects so their left edges are aligned to the left edge of the primary selected object.
- **Align Top** - Move objects so their top edges are aligned to the top edge of the primary selected object.
- **Align Right** - Move objects so their right edges are aligned to the right edge of the primary selected object.
- **Align Bottom** - Move objects so their bottom edges are aligned to the bottom edge of the primary selected object.
- **Center Horizontally** - Move objects so that their centroid is centered horizontally in the form.
- **Center Vertically** - Move objects so that their centroid is centered vertically in the form.
- **Space Across** - Space objects evenly across the form in a horizontal direction.
- **Space Down** - Space objects evenly up and down the form in a vertical direction.
- **Same Width** - Resize objects so that the width of all is the same as the width of the primary selected object.
- **Same Width (Max)** - Resize objects so that the width of all is the same as the width of the widest object.
**Alignment Example**

To align the controls above, we begin by selecting them.

Press the **Align Left** command in the **Alignment toolbar**.

The controls will instantly align so that the left margin of each is lined up with the leftmost margin of the primary selected control. In this case, the primary control was the text box.
Clicking the Select None button in the selection toolbar to deselect all the controls shows us the new, improved, neat and clean controls arrangement. Excellent! ... Now we can get back to downloading mp3's...

Seeing Controls in their Run Time Form

Many controls in forms will change their appearance from design time to run time. Push the Test button (or right click on the form and choose Test from the context menu) to see the form in its run time appearance. The Test run will allow many controls to function visually as well, so tabs may be clicked or command buttons pressed to test the visual behavior of controls during run time. However, it is not the same as running the actual form / script combination. In particular, if a control is scripted to close the form it will not work from the Test environment. Therefore, if one does not equip the form with a Control Box “X” close button in the upper right corner there will be no obvious way to close the form when Test is run. In such cases, use ALT-F4 to close the form.

Tech Tips

Remember to unclick a control creation tool (such as Insert Check Box) before reaching into the form window to move things about. Otherwise, you’ll end up creating lots of little check boxes on top of each other when you think you are clicking and dragging controls about.

Remember to unclick a selection mode box (such as Select Box) before doing trying to move or resize. Otherwise, the move and resize cursors won’t appear because the system thinks you still want to select things.

If you edit a form’s properties to eliminate the System Menu or to make it borderless, you may end up with a form that provides no way to Close the form when it is tested. In such cases use ALT F4 to close the form since this keyboard shortcut to closing is always enabled.

Since the grid does not appear within controls, this effect can interfere with placing controls within a frame, since the interior of the frame will also be grid-free. Mouse action will still be aligned to the grid if Snap to Grid is on, but we won’t see the grid within the frame control. To see the grid when inserting controls within a frame, draw clusters of controls and then draw frames that contain them.

Suppose we’ve drawn two checkbox controls using the grid.

Using the Insert Frame control we draw a frame.
The frame appears on top of the checkbox controls. The checkbox controls cannot be seen because the frame’s interior is solid.

We push out the **Insert Frame** button to turn off that command and then click on the new frame to select it. We can then right click on the frame and choose **Order - Move to Bottom** to move the control below the checkboxes.

We can now see the checkbox controls. If desired, we can select them and move them about together for precise placement within the frame.

Most professional programmers work with a grid on and **Snap to Grid** enabled. Using grids together with smart mouse selection (with keyboard modifiers), use of keyboard arrow keys to move and resize controls and the **Alignment toolbar** controls results in fast and accurate form creation.
Forms and Scripts

Creating a form automatically creates an empty script that is associated with the form. The script refers to controls in the form to achieve the programmatic functioning desired for the form.

By default, the script uses VBScript language. Suppose we create a new form in the project. The minimum script created by default simply shows the form:

```vbnet
Sub Main
    Form.Visible = True
End Sub
```

We can write a more elaborate script that upon the press of a button displays a message box showing "Hello, World!" To do this, we would first add a command button to the form.

Using the Insert Command Button tool insert a command button into the form as described in the Editing Forms topic. Right click onto the new command button, choose Properties and in the Control tab change the default Name to Hello and in the General tab change the default Caption to Hello.

The form with the new command button is seen above in a form window open for editing. We can now click open the form's script and add code to handle a click of the Hello button. This will be an additional Sub:

```vbnet
Sub Main
    Form.Visible = True
End Sub

' -- Launch message box on click
Sub Hello_Click
    MsgBox "Hello, World!"
End Sub
```

If we run the form from the project pane it creates a form:

Every time we click the Hello button a message box will launch with our desired text:
We can click **OK** on the message box and then click **Hello** to display the message again as often as we like. To close the form we can click on the **X** box in the upper right corner. We can add a second button, a **Close** button that will close the form using our own command button.

To do so we use the Insert Command Button tool again to insert a second command button into the form. Right click onto the new command button, choose **Properties** and in the **Control** tab change the default **Name** to **Close** and in the **General** tab change the default **Caption** to **Close**.

After a little tinkering with the alignment commands as described in the Editing Forms topic we have two buttons that are the same size and neatly aligned.

In the form's script we add a **Sub** to handle clicks of the **Close** button:

```vbnet
Sub Main
    Form.Visible = True
End Sub

' -- Launch message box on click
Sub Hello_Click
    MsgBox "Hello, World!"
End Sub

' -- close form
Sub Close_Click
    Form.Visible = False
End Sub
```

Running the form now shows it has two command buttons. The **Hello** button pops open a message box and the **Close** button closes the form.

A more sophisticated form would use controls like text boxes to display text that is generated programmatically. For example, we might create a form to view the contents of the **Employees** table of the **Nwind.mdb** sample database:
The script that powers this form is directly analogous to the simple example with two buttons. The script launches with a Main routine that makes the form visible. A Close button closes the form. Routines for each button apply some program logic and call the Reload routine to redisplay the form. The Reload routine loads up the various text boxes with appropriate text strings taken from the table record.

' -- launch form on startup
Sub Main
    Form.Visible = True
End Sub

' ---------------------------
Dim Employees
EmployeeIndex = -1
EmployeeCount = 10

' ---------------------------

' -- jump to first employee on load
Sub Form_OnLoad

    ' -- set up global variables
    Set Components = Application.ActiveDocument.ComponentSet
    EmpPos = Components.ItemByName("Employees")
    If EmpPos < 0 Then
        MsgBox ":'Employees' table not found."
        Form.Visible = False
    End If
    Set Employees = Components(EmpPos)
    EmployeeIndex = 0
    EmployeeCount = Employees.RecordSet.Count

    ' -- load controls
    Reload

End Sub

Notes: Education includes a BA in Psychology from Colorado State University in 1970. She also completed "The Art of the Cold Call." Nancy is a member of Toastmasters International.
End Sub

' -- close form
Sub Close_Click
    Form.Visible = False
End Sub

' -- jump to first employee
Sub First_Click
    If EmployeeIndex <> 0 Then
        EmployeeIndex = 0
        Reload
    End If
End Sub

' -- jump to last employee
Sub Last_Click
    If EmployeeIndex <> EmployeeCount-1 Then
        EmployeeIndex = EmployeeCount-1
        Reload
    End If
End Sub

' -- jump to next employee if any
Sub Next_Click
    If EmployeeIndex < EmployeeCount-1 Then
        EmployeeIndex = EmployeeIndex+1
        Reload
    End If
End Sub

' -- jump to previous employee if any
Sub Previous_Click
    If EmployeeIndex > 0 Then
        EmployeeIndex = EmployeeIndex-1
        Reload
    End If
End Sub

' -- load current employee
Sub Reload
    Set Rec = Employees.RecordSet(EmployeeIndex)

    ' -- set employee readouts
    Employee.Text = Rec.Data("First Name") & " " & Rec.Data("Last Name") & " (#" & CStr(EmployeeIndex+1) & ")"]
    Title.Text = Rec.Data("Title")
    BirthDate.Text = Rec.Data("Birth Date")
    HireDate.Text = Rec.Data("Hire Date")
    Country.Text = Rec.Data("Country")
    Region.Text = Rec.Data("Region")
    City.Text = Rec.Data("City")
    PostalCode.Text = Rec.Data("Postal Code")
Address.Text = Rec.Data("Address")
Notes.Text = Rec.Data("Notes")
End Sub

We've named the text box controls the same as the text captions (which are separate controls), so that code like...

Region.Text = Rec.Data("Region")

... refers to the text box named Region.

The form shown above allows us to step through the Employees table using First, Previous, Next and Last buttons. With each press of a button the appropriate record info will be displayed in the text boxes. The form is intended as a simple example but even so it is quite useful.

We could extend the form above by adding one more button, a Select button to select the record currently shown in the table. Just like adding buttons in the two button example at the beginning of this topic, we use the Insert Command Button tool to draw a new command button in the form. Right click onto the new command button, choose Properties and in the Control tab change the default Name to Select and in the General tab change the default Caption to Select. Use the alignment tools to make the button the same size as the other buttons and aligned neatly in the same row. We've placed the new Select button in the lower left corner of the form.

We can then add one more Sub to the script to handle any clicks of the Select button:

Sub Select_Click
' clear any selection
Set records = Employees.RecordSet
For nItem = 0 To records.Count-1
    Set record = records(nItem)
    record.Mask = record.Mask And Not 1
Next
' create selection
Set record = Employees.RecordSet(EmployeeIndex)
record.Mask = record.Mask Or 1
End Sub

This routine first clears the selection and then selects whatever is the current employee seen in the form.

Using Languages other than VBScript

Form scripts can use languages other than VBScript, for example, Javascript. The syntax of event handlers will vary from language to language.

Here is the Javascript version of the script for the form discussed at the beginning of this topic:

function Main() {
    Form.Visible = true;
}

function Hello::Click() {

Note that form scripts cannot use .NET languages such as C# or VB .NET. This is only a minor issue since .NET scripts can create forms in code, without using form components, through the use of Windows Forms. Advanced script writers will also frequently design forms outside of Manifold using Visual Studio .NET or other tools, and call these forms from Manifold scripts.

Frequently Used Controls

Control - Tools Toolbar

The Tools toolbar when used with forms hosts the most frequently used controls in Forms. There are many more controls available in the advanced tools toolbar. For advanced controls, see the Tools (Advanced) toolbar topic.

Click on a control in the Tools toolbar and then click and drag in the Form window to insert the control in the form in the position and size indicated by the mouse click and drag. Forms are then customized using the properties for each control.

Some attributes of controls, such as their size or position are properties not of the control but of the container for the control, in this case the Form itself. To change the size or position of controls we can simply click on them and resize or drag them to a new position.

Properties normally both return and set that particular property. The easiest way to edit properties is through the context menu's properties dialog for that control.

See the individual controls topics for details on each control.

**Insert Check Box** - Inserts check box controls.

**Insert Option Button** - Inserts option button controls. Only one option button in a group may be selected.

**Insert Command Button** - Inserts command button controls.

**Insert Frame** - Draws frame with caption. Frames are used to set off groups of controls, often option buttons.

**Insert Text Box** - Inserts text box. Also called an edit field or edit control. This control can display text entered by the programmer at design time or entered by the user or assigned to the control by other code at run time.

**Insert List Box** - Inserts list box controls.

**Insert Combo Box** - Inserts combo box controls.

**Insert Horizontal Scroll Bar** - Inserts horizontal scroll bar controls.

**Insert Vertical Scroll Bar** - Inserts vertical scroll bar controls.

Lightweight Controls
Manifold System implements the above controls using Microsoft's "windowless" lightweight ActiveX controls found in the Microsoft MSWLess.ocx file. Lightweight controls do not have an hWnd property, which dramatically conserves computer resources and enables rapid launch. Also, Dynamic Data Exchange (DDE) is not supported within lightweight controls. In all other aspects the lightweight version of the control works exactly the same as the standard VB version. There is a simple "group" substitute in the one case where the windowless nature of the controls has an effect, and there are many other choices other than DDE within Microsoft data access methodology. For these reasons, use of lightweight controls has no negative impact in scripts.

Microsoft's MSWLess.ocx ActiveX controls used within Manifold are **Unicode-enabled**. Following standard Windows practise, no conversion of Unicode data occurs when used within a Unicode-aware operating system such as Microsoft Windows Server 2003, Windows XP or Microsoft Windows 2000. The control will pass data with no conversion involved in such systems. When used within non-Unicode-enabled operating Windows editions (so long as such may be supported), data will be converted from ANSI to Unicode and back.

**Note:** All properties and controls from the lightweight series are prefaced with "wl" to indicate they are the windowless lightweight versions of the controls and properties settings. The "wl" prefix is suppressed in the documentation below to enhance legibility.

**Using the Group Property**

For the most part, the windowless nature of Microsoft lightweight controls does not interfere with the creation of whatever form we like. The key exception is the use of frames to group option buttons. In VB, frames are windows and will automatically group controls, such as option buttons, within them. This lets the system automatically require that only one option button within the same frame be chosen. It is standard practice within VB to segregate OptionButton controls within their own Frame control.

With windowless controls, we need to set the group property of each object that is to be in a particular group to the same unique string. For example, we might draw a frame called Truck Display Options that included three option buttons labeled Ahead, On Time and Delayed. Assuming we named our option buttons in a way that is easy to remember, we could assign each of these three option buttons to the same group with:

```vbnet
Ahead.Group = "TruckDisplayOption"
OnTime.Group = "TruckDisplayOption"
Delayed.Group = "TruckDisplayOption"
```

The string can be whatever we want it to be as long as it is unique for each group desired. It's usually wise to use a string that is self-documenting.

The above is not necessary with VB, but then again in VB it is really easy to not create controls in a form in the right order and so end up thinking that a control is in a frame when it is not (it's just positioned above the frame). Declaring the group property for each option button in the above explicit fashion eliminates such possible errors.

**Other Controls**

The controls in the Tools (Advanced) toolbar as well as all other controls in .ocx files provided with manifold are implemented using standard Microsoft window controls having an hWnd property.

**Form Properties for Controls**

Manifold adds an extra tab, the Control tab, to the usual tabs that appear in the design time properties dialog for controls. This tab provides access to the properties for this control maintained by the form. This extra tab will appear at design time for all controls. Although strictly speaking these are properties of the form that is the container for the control and not of the control, they are easiest to specify at design time if they appear within each control's properties dialog.

**Control**

- **Name**  The name used by the form to identify this control.
- **Tag**    A string available for free use by the programmer. Often used for comments.
Left  Left margin position of the control.
Top   Top margin position of the control.
Width Width of the control.
Height Height of the control.
Visible Make this control visible or invisible.
Control - Check Box

Insert a check box into the form.

To Add a Check Box to a Form

1. Click on the Insert Check Box button in the Tools toolbar.
2. Click and drag the location and size where it is to be created in the form.
3. Continue to create any additional check boxes desired.
4. Right click onto each check box and choose Properties from the context menu.
5. Set the properties for the check box as desired.
6. Move, resize and align the check box as desired.

Properties normally both return and set that particular property. The easiest way to edit properties is through the context menu's properties dialog for that control.

Some attributes of controls, such as their size or position are properties not of the control but of the container for the control, in this case the Form itself. To change the size or position of controls we can simply click on them and resize or drag them to a new position.

Keep in mind that programs can change the properties of controls at run time. Although this documentation is written as though the properties are set at design time using the Properties dialog for this control, there are many situations in which program code will be used to change a control's properties at run time.

Note: All properties and controls are prefaced with "wl" to indicate they are the windowless lightweight versions of the controls and properties settings. The "wl" prefix is suppressed in the documentation below to enhance legibility.

Properties

In addition to the properties listed below, a Control tab provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

Check Box

General

Caption  Text used to label the check box. Font is set in the font tab.

MousePointer  The type of mouse pointer displayed when over the check box. Choose from 16 different types plus a custom pointer.

Appearance  3D or Flat. 3D is the standard Windows look.

Alignment  Places check box to left or right of caption within the size of the control.

OLEDropMode  Set to None (default) if the check box does not accept OLE drops and is to display the No Drop cursor if an OLE drop is attempted. Set to Manual, the check box will trigger OLE drop events, allowing programs to handle the OLE drop operation in code.

Style  Standard (default) or Graphical. In Standard style check boxes display as a box/button with the caption label next to it. In graphical style, check boxes display as a button that can be pushed in/out and may also display an associated graphic.

Value  Default state of the control: Unchecked, Checked and Grayed (dimmed).
**Enabled**
True or False. True means the object can respond to user-generated events, false prevents it from responding. We can disable a control like a text box if we wish it to simply display information in a read-only way.

**UseMaskColor**
If checked, enables use of mask color in a button's picture if the **Style** is set to graphical. A mask color is the color that is to be made transparent.

### Color

**Back Color**
Color to be used for the check box's background, normally seen only when Flat **Style** is used.

**Fore Color**
Color to be used for the check box's foreground, the color of the text caption.

**Mask Color**
Color to be treated as transparent in an image used with the button when **UseMaskColor** is checked and **Style** is set to graphical.

**Color Set**
Choose from Standard Colors (standard Windows non-dithered colors) or Windows System Colors. The latter will be defined by the user's Control Panel settings and is normally the setting used so that the form changes appearance like the rest of Windows if the Control Panel settings are changed.

**Color Palette**
Displays available colors. Click on the property to be changed to highlight it in the **Properties** pane, click on the desired color in the **Color Palette** pane and then press **Apply**.

**Edit Custom Color**
Change the custom color presented in the **Color Palette** when the **Color Set** is set to Windows System Colors.

### Font

**Properties**
Font properties that may be changes.

**Font**
Choose a font installed on this system. It's wise to choose standard Windows fonts such as **MS Sans Serif** that are universally available.

**Size**
Size of font, in points.

**Effects**
Bold, Italic, Underline or Strikeout.

**Sample Text**
A preview of the selected settings.

### Picture

**DisabledPicture**
Graphic to show when control is disabled if **Style** is set to graphical.

**DownPicture**
Graphic to show on an enabled control in the DOWN position if **Style** is set to graphical.

**MouseIcon**
Custom icon to use when the **MousePointer** property is set to 99. Like Visual Basic, will not load animated cursor (**.ani**) files.

**Picture**
Graphic to show on an enabled control in the UP position if **Style** is set to graphical.
Note: graphics are loaded at design time and saved within the project. When browsing to find the graphic to be used, .bmp, .ico, .wmf, .gif or .jpeg files may be used.

Examples

Check boxes are often used as "mode" buttons in graphical style. Suppose we want our form to control the display of a map that shows airports, bus stations and train stations. Using Manifold's image capabilities, we have created six small images, each of which is 30 x 30 pixels in size:

The gray versions are simply copies of the green versions that were desaturated and had the lightness increased using Manifold's Hue / Saturation command. We first create three check boxes and clear their caption property:

In the default standard style they are just ordinary check boxes. We have created these check boxes with a Height and a Width of 40 pixels each.

If we choose graphical style for each of the check boxes, they appear as a 3D button.
We can also choose the **Picture** property for each of them to use the gray picture in their "up" position.

For the **DownPicture** property we use the green picture.

When the form is run, pressing the button (equivalent to checking the check box) switches the green picture into the button. This is a nice way of emphasizing that this button is pushed in. In the illustration above we have chosen airports and bus stations.
Here, we have chosen just train stations.

**Note:** It's very cool we can use graphics so easily in Manifold forms. However, one should use them with restraint to avoid cluttering up forms with distracting graphical junk. Sometimes a plain check box is a better approach.
Control - Option Button

Option buttons (also called radio buttons in programmer slang) are used for choices where only one choice in a group is allowed.

To Add an Option Button to a Form

1. Click on the Insert Option Button button in the Tools toolbar.
2. Click and drag the location and size where it is to be created in the form.
3. Continue to create any additional option buttons desired.
4. Right click onto each button and choose Properties from the context menu.
5. Set the properties for the option button as desired. Note that each option button must belong to a group.
6. Move, resize and align the option button as desired.

Properties normally both return and set that particular property. The easiest way to edit properties is through the context menu’s properties dialog for that control.

Some attributes of controls, such as their size or position are properties not of the control but of the container for the control, in this case the Form itself. To change the size or position of controls we can simply click on them and resize or drag them to a new position.

Keep in mind that programs can change the properties of controls at run time. Although this documentation is written as though the properties are set at design time using the Properties dialog for this control, there are many situations in which program code will be used to change a control's properties at run time.

Note: All properties and controls are prefaced with "wl" to indicate they are the windowless lightweight versions of the controls and properties settings. The "wl" prefix is suppressed in the documentation below to enhance legibility.

Using the Group Property

For the most part, the windowless nature of Microsoft lightweight controls does not interfere with the creation of whatever form we like. The key exception is the use of frames to group option buttons. In VB, frames are windows and will automatically group controls, such as option buttons, within them. This lets the system automatically require that only one option button within the same frame be chosen. It is standard practice within VB to segregate OptionButton controls within their own Frame control.

With windowless controls, we need to set the group property of each object that is to be in a particular group to the same unique string. For example, we might draw a frame called Truck Display Options that included three option buttons labeled Ahead, On Time and Delayed. Assuming we named our option buttons in a way that is easy to remember, we could assign each of these three option buttons to the same group with:

```
Ahead.Group = "TruckDisplayOption"
OnTime.Group = "TruckDisplayOption"
Delayed.Group = "TruckDisplayOption"
```

The string can be whatever we want it to be as long as it is unique for each group desired. It's usually wise to use a string that is self-documenting.

Default Values for Option Buttons

One and only one option button in a group should have a True value at all times. Because option buttons are created by default with a False value, after creating all of the option buttons in a group and setting their Group property to the same string, one of the buttons should have its Value box checked True so that it is by default the ON button.

Properties
In addition to the properties listed below, a Control tab provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

Option Button

**General**

**Caption** Text used to label the option button. Font is set in the font tab.

**Group** A text string. All option buttons with the same text string are considered part of the same group. Checking one option button in a group will uncheck all other option buttons in that group.

**MousePointer** The type of mouse pointer displayed when over the option button. Choose from 16 different types plus a custom pointer.

**Appearance** 3D or Flat. 3D is the standard Windows look.

**Alignment** Places option button to left or right of caption within the size of the control.

**OLEDropMode** Set to None (default) if the option button does not accept OLE drops and is to display the No Drop cursor if an OLE drop is attempted. Set to Manual, the option button will trigger OLE drop events, allowing programs to handle the OLE drop operation in code.

**Style** Standard (default) or Graphical. In Standard style option buttons display as a box/button with the caption label next to it. In graphical style, option buttons display as a button that can be pushed in/out, and may also display an associated graphic.

**Value** Default state of the control: Unchecked, Checked and Grayed (dimmed). Only one option button in a group can be checked.

**Enabled** True or False. True means the object can respond to user-generated events, false prevents it from responding. We can disable a control like a text box if we wish it to simply display information in a read-only way.

**UseMaskColor** If checked, enables use of mask color in a button’s picture if the Style is set to graphical. A mask color is the color that is to be made transparent.

**Color**

**Back Color** Color to be used for the option button’s background, normally seen only when Flat Style is used.

**Fore Color** Color to be used for the option button’s foreground, the color of the text caption.

**Mask Color** Color to be treated as transparent in an image used with the button when UseMaskColor is checked and Style is set to graphical.

**Color Set** Choose from Standard Colors (standard Windows non-dithered colors) or Windows System Colors. The latter will be defined by the user's Control Panel settings and is normally the setting used so that the form changes appearance like the rest of Windows if the Control Panel settings are changed.

**Color Palette** Displays available colors. Click on the property to be changed to highlight it in the Properties pane, click on the desired color in the Color Palette pane and then
Edit Custom Color

Change the custom color presented in the Color Palette when the Color Set is set to Windows System Colors.

Font

Properties

Font properties that may be changes.

Font

Choose a font installed on this system. It's wise to choose standard Windows fonts such as MS Sans Serif that are universally available.

Size

Size of font, in points.

Effects

Bold, Italic, Underline or Strikeout.

Sample Text

A preview of the selected settings.

Picture

DisabledPicture

Graphic to show when control is disabled if Style is set to graphical.

DownPicture

Graphic to show on an enabled control in the DOWN position if Style is set to graphical.

MouseIcon

Custom icon to use when the MousePointer property is set to 99. Like Visual Basic, will not load animated cursor (.ani) files.

Picture

Graphic to show on an enabled control in the UP position if Style is set to graphical.

Note: graphics are loaded at design time and saved within the project. When browsing to find the graphic to be used, .bmp, .ico, .wmf, .gif or .jpeg files may be used.

Examples

We will use a graphical style for this particular option button and also add a picture.

Default option button with standard Style.

The same button with graphical Style. The size of the 3D graphical button is set by the size of the control as shown in the form editor when it is selected.
To add a picture to this control, we use the Properties dialog's Picture tab as shown above.

The result is a picture. To get rid of the white background, we can check UseMaskColor and set the mask color to white.

That's better!

Note: To create this example, we used one of the standard manifold.net images from our corporate clip-art collection. The particular picture used had been optimized for use on web sites and so includes some anti-aliasing pixels in lighter colors on the edges of the red and yellow triangles. These anti-aliasing pixels are lighter shades of color between pure white and red. Using a pure white mask color to get rid of the background will leave the anti-aliasing pixels in place to provide a slight "halo" of lighter pixels that are visible in some spots against the gray color of the button. We can eliminate this effect by using an image that does not include anti-aliasing pixels in the first place.
**Control - Command Button**

Command buttons are used to issue commands in a form. The **OK** and **Cancel** buttons often seen in Windows dialogs are command buttons, for example.

**To Add a Command button to a Form**

1. Click on the **Insert Command button** button in the **Tools toolbar**.
2. Click and drag the location and size where it is to be created in the form.
3. Continue to create any additional command buttons desired.
4. Right click onto each command button and choose **Properties** from the context menu.
5. Set the properties for the command button as desired.
6. Move, resize and align the command button as desired.

Properties normally both return and set that particular property. The easiest way to edit properties is through the context menu’s **properties** dialog for that control.

Some attributes of controls, such as their size or position are properties not of the control but of the container for the control, in this case the Form itself. To change the size or position of controls we can simply click on them and resize or drag them to a new position.

Keep in mind that programs can change the properties of controls at run time. Although this documentation is written as though the properties are set at design time using the **Properties** dialog for this control, there are many situations in which program code will be used to change a control’s properties at run time.

**Note:** All properties and controls are prefaced with "wl" to indicate they are the windowless lightweight versions of the controls and properties settings. The "wl" prefix is suppressed in the documentation below to enhance legibility.

**Properties**

In addition to the properties listed below, a **Control tab** provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

**Command Button**

**General**

- **Caption** Text used to label the command button. Font is set in the font tab.
- **MousePointer** The type of mouse pointer displayed when over the command button. Choose from 16 different types plus a custom pointer.
- **Appearance** 3D or Flat. 3D is the standard Windows look. Flat has no effect with command buttons.
- **OLEDropMode** Set to None (default) if the command button does not accept OLE drops and is to display the No Drop cursor if an OLE drop is attempted. Set to Manual, the command button will trigger OLE drop events, allowing programs to handle the OLE drop operation in code.
- **Style** Standard (default) or Graphical. In standard style command buttons display as a button with the caption on top. In graphical style, command buttons may also display an associated graphic.
- **Enabled** True or False. True means the object can respond to user-generated events, false prevents it from responding. We can disable a control like a text box if we wish it to simply display information in a read-only way.
UseMaskColor  If checked, enables use of mask color in a button’s picture if the Style is set to graphical. A mask color is the color that is to be made transparent.

Color

Back Color  Color to be used for the command button’s background, normally seen only when Flat Style is used.

Fore Color  Color to be used for the command button’s foreground, the color of the text caption.

Mask Color  Color to be treated as transparent in an image used with the button when UseMaskColor is checked and Style is set to graphical.

Color Set  Choose from Standard Colors (standard Windows non-dithered colors) or Windows System Colors. The latter will be defined by the user’s Control Panel settings and is normally the setting used so that the form changes appearance like the rest of Windows if the Control Panel settings are changed.

Color Palette  Displays available colors. Click on the property to be changed to highlight it in the Properties pane, click on the desired color in the Color Palette pane and then press Apply.

Edit Custom Color  Change the custom color presented in the Color Palette when the Color Set is set to Windows System Colors.

Font

Properties  Font properties that may be changes.

Font  Choose a font installed on this system. It’s wise to choose standard Windows fonts such as MS Sans Serif that are universally available.

Size  Size of font, in points.

Effects  Bold, Italic, Underline or Strikeout.

Sample Text  A preview of the selected settings.

Picture

DisabledPicture  Graphic to show when control is disabled if Style is set to graphical.

DownPicture  Graphic to show on an enabled control in the DOWN position if Style is set to graphical.

MouseIcon  Custom icon to use when the MousePointer property is set to 99. Like Visual Basic, will not load animated cursor (.ani) files.

Picture  Graphic to show on an enabled control in the UP position if Style is set to graphical.

Note: graphics are loaded at design time and saved within the project. When browsing to find the graphic to be used, .bmp, .ico, .wmf, .gif or .jpeg files may be used.
Control - Frame

Frames are used to provide a border within the form that includes a caption. Frames are used to organize forms.

Frames are also used to organize option buttons into related groups. In compiled Visual Basic, frames will automatically group option buttons if the option buttons and frames are created in the correct sequence. In Manifold, frames are simply visual artifacts used to organize the form. We can use the group property of option buttons (see below) to organize them in a standard VB way.

To Add an Frame to a Form

1. Click on the Insert Frame button in the Tools toolbar.
2. Click and drag the location and size where it is to be created in the form.
3. Continue to create any additional frames desired.
4. Right click onto each button and choose Properties from the context menu.
5. Set the properties for the frame as desired. Note that each frame must belong to a group.
6. Move, resize and align the frame as desired.

Properties normally both return and set that particular property. The easiest way to edit properties is through the context menu's properties dialog for that control.

Some attributes of controls, such as their size or position are properties not of the control but of the container for the control, in this case the Form itself. To change the size or position of controls we can simply click on them and resize or drag them to a new position.

Keep in mind that programs can change the properties of controls at run time. Although this documentation is written as though the properties are set at design time using the Properties dialog for this control, there are many situations in which program code will be used to change a control's properties at run time.

Note: All properties and controls are prefaced with "wl" to indicate they are the windowless lightweight versions of the controls and properties settings. The "wl" prefix is suppressed in the documentation below to enhance legibility.

Using the Group Property

For the most part, the windowless nature of Microsoft lightweight controls does not interfere with the creation of whatever form we like. The key exception is the use of frames to group option buttons. In VB, frames are windows and will automatically group controls, such as option buttons, within them. This lets the system automatically require that only one option button within the same frame be chosen. It is standard practice within VB to segregate OptionButton controls within their own Frame control.

With windowless controls such as the frames control used within Manifold, we need to set the group property of each object that is to be in a particular group to the same unique string. For example, we might draw a frame called Truck Display Options that included three option buttons labeled Ahead, On Time and Delayed. Assuming we named our option buttons in a way that is easy to remember, we could assign each of these three option buttons to the same group with:

```vbnet
Ahead.Group = "TruckDisplayOption"
OnTime.Group = "TruckDisplayOption"
Delayed.Group = "TruckDisplayOption"
```

The string can be whatever we want it to be as long as it is unique for each group desired. It's usually wise to use a string that is self-documenting.

Properties

In addition to the properties listed below, a Control tab provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.
Frame

General

Caption  Text used to label the frame. Font is set in the font tab.

MousePointer  The type of mouse pointer displayed when over the frame. Choose from 16 different types plus a custom pointer

Appearance  3D or Flat. 3D is the standard Windows look. Flat results in a rectangular square of background color with a foreground color border and caption.

BorderStyle  FixedSingle (default) or None. None may be used with Flat Appearance to achieve an uncaptioned rectangle of background color.

OLEDropMode  Set to None (default) if the frame does not accept OLE drops and is to display the No Drop cursor if an OLE drop is attempted. Set to Manual, the frame will trigger OLE drop events, allowing programs to handle the OLE drop operation in code.

Enabled  True or False. True means the object can respond to user-generated events, false prevents it from responding. We can disable a control like a text box if we wish it to simply display information in a read-only way.

Color

Back Color  Color to be used for the frame's background, normally seen only when Flat Style is used.

Fore Color  Color to be used for the frame's foreground, the color of the text caption.

Color Set  Choose from Standard Colors (standard Windows non-dithered colors) or Windows System Colors. The latter will be defined by the user's Control Panel settings and is normally the setting used so that the form changes appearance like the rest of Windows if the Control Panel settings are changed.

Color Palette  Displays available colors. Click on the property to be changed to highlight it in the Properties pane, click on the desired color in the Color Palette pane and then press Apply.

Edit Custom Color  Change the custom color presented in the Color Palette when the Color Set is set to Windows System Colors.

Font

Properties  Font properties that may be changes.

Font  Choose a font installed on this system. It's wise to choose standard Windows fonts such as MS Sans Serif that are universally available.

Size  Size of font, in points.

Effects  Bold, Italic, Underline or Strikeout.

Sample Text  A preview of the selected settings.
Examples

- Truck Display Options
  - Ahead
  - On Time
  - Delayed
  - Update
Control - Text Box

Text boxes are used to display text and to accept text entry from users. They may be used either dynamically to display text from various data sources or (something of a kludge, but very handy) as a means of creating fixed labels within forms, built-in documentation or other fixed text.

At run time, Windows will provide text boxes with the full set of keyboard and text navigation controls normally associated with text in Windows.

To Add a Text Box to a Form

1. Click on the Insert Text box button in the Tools toolbar.
2. Click and drag the location and size where it is to be created in the form.
3. Continue to create any additional text boxes desired.
4. Right click onto each text box and choose Properties from the context menu.
5. Set the properties for the text box as desired.
6. Move, resize and align the text box as desired.

Properties normally both return and set that particular property. The easiest way to edit properties is through the context menu's properties dialog for that control.

Some attributes of controls, such as their size or position are properties not of the control but of the container for the control, in this case the Form itself. To change the size or position of controls we can simply click on them and resize or drag them to a new position.

Keep in mind that programs can change the properties of controls at run time. Although this documentation is written as though the properties are set at design time using the Properties dialog for this control, there are many situations in which program code will be used to change a control's properties at run time.

Note: All properties and controls are prefaced with "wl" to indicate they are the windowless lightweight versions of the controls and properties settings. The "wl" prefix is suppressed in the documentation below to enhance legibility.

Properties

In addition to the properties listed below, a Control tab provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

Text box

General

MousePointer The type of mouse pointer displayed when over the text box. Choose from 16 different types plus a custom pointer
Alignment  Left justify, right justify, or center the text in the box.
Appearance  3D or Flat. 3D is the standard Windows look. Flat results in a rectangular square of background color with a foreground color border.
BorderStyle  FixedSingle (default) or None. None may be used with Flat Appearance to achieve an uncaptioned rectangle of background color.
OLEDragMode  DragManual (default) or DragAutomatic. DragManual means the program handles all OLE drag/drop operations, while DragAutomatic means the text box handles all OLE drag/drop operations.
OLEDropMode  Set to None (default) if the text box does not accept OLE drops and is to display the No Drop cursor if an OLE drop is attempted. Set to Manual, the text box will trigger OLE
Programming

don't events, allowing programs to handle the OLE drop
operation in code.

**ScrollBars**
NoScrollbars, Horizontal, Vertical or Both. Set as desired
to cause scroll bars to appear. Scroll bars appear only if
**MultiLine** is set True (checked). Scroll bars will always
appear in text boxes if enabled by this property even if the
text does not extend beyond the borders of the box.

**Enabled**
True or False. True means the object can respond to
user-generated events, false prevents it from responding.
We can disable a control like a text box if we wish it to
simply display information in a read-only way.

**HideSelection**
True or False. True means that highlighted text will not
appear highlighted when the text box loses the focus.
False means that highlighted text stays highlighted even
when another form or dialog has the focus.

**Locked**
True or False. True means the user can scroll and
highlight the text in the box but cannot change it. The
program can change the text by modifying the text box's
**Text** property. False (default) means users can edit the
text in the text box.

**MultiLine**
True or False. True (checked) enables multiple lines of
text. A multiple line text box will wrap text as the user
enters text that extends past the text box. If a horizontal
scroll bar is present text will not wrap. On a form with no
default button, pressing ENTER in a multiple line text box
will move the focus to the next line. If a default button
exists in the form, the user must press CTRL Enter to
move to the next line.

**PasswordChar**
Used to create password boxes in dialogs. Placing any
character or string in this box sets that character (or,
the first character in the field) as the character to use for
whatever is typed into that box. Virtually all applications
use the asterisk character. If the **MultiLine** property is
set True, setting the **PasswordChar** property will have no
effect.

**MaxLength**
An integer that limits the number of characters that can
be entered into the text box. Default is 0, meaning no
limit. Text exceeding the given value in length will have
extra characters truncated.

**Text**
**Text** Text contents for this text box.

**Color**

**Back Color**
Color to be used for the text box's background.

**Fore Color**
Color to be used for the text box's foreground, the color of
the text caption.

**Color Set**
Choose from Standard Colors (standard Windows non-
dithered colors) or Windows System Colors. The latter
will be defined by the user's Control Panel settings and is
normally the setting used so that the form changes
appearance like the rest of Windows if the Control Panel
settings are changed.

**Color Palette**
Displays available colors. Click on the property to be
changed to highlight it in the **Properties** pane, click on
the desired color in the **Color Palette** pane and then
press **Apply**.
### Edit Custom Color
Change the custom color presented in the **Color Palette** when the **Color Set** is set to Windows System Colors.

### Font Properties
Font properties that may be changed.

- **Font**
  Choose a font installed on this system. It's wise to choose standard Windows fonts such as **MS Sans Serif** that are universally available.

- **Size**
  Size of font, in points.

- **Effects**
  Bold, Italic, Underline or Strikeout.

- **Sample Text**
  A preview of the selected settings.
Control - Static Text Box

Static text boxes are used to display text not modified by users. Static text boxes are a variation of ordinary, editable text boxes.

To Add a Text Box to a Form

1. Click on the Insert Static Text Box button in the Tools toolbar.
2. Click and drag the location and size where it is to be created in the form.
3. Continue to create any additional text boxes desired.
4. Right click onto each text box and choose Properties from the context menu.
5. Set the properties for the text box as desired.
6. Move, resize and align the text box as desired.

Properties normally both return and set that particular property. The easiest way to edit properties is through the context menu’s properties dialog for that control.

Some attributes of controls, such as their size or position are properties not of the control but of the container for the control, in this case the Form itself. To change the size or position of controls we can simply click on them and resize or drag them to a new position.

Keep in mind that programs can change the properties of controls at run time. Although this documentation is written as though the properties are set at design time using the Properties dialog for this control, there are many situations in which program code will be used to change a control’s properties at run time.

**Note:** All properties and controls are prefaced with "wl" to indicate they are the windowless lightweight versions of the controls and properties settings. The "wl" prefix is suppressed in the documentation below to enhance legibility.

### Properties

In addition to the properties listed below, a Control tab provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

Control - List Box

List boxes are used to display a list of items from which one or more items can be selected. If there are more items than will fit in the drop-down list, a scroll bar will be automatically added.

To create a list box that is a drop down menu style of list box, use a Combo Box control with Style set to DropdownList.

To Add a List box to a Form

1. Click on the Insert List box button in the Tools toolbar.
2. Click and drag the location and size where it is to be created in the form.
3. Continue to create any additional list boxes desired.
4. Right click onto each list box and choose Properties from the context menu.
5. Set the properties for the list box as desired.
6. Move, resize and align the list box as desired.

Properties normally both return and set that particular property. The easiest way to edit properties is through the context menu's properties dialog for that control.

Some attributes of controls, such as their size or position are properties not of the control but of the container for the control, in this case the Form itself. To change the size or position of controls we can simply click on them and resize or drag them to a new position.

Keep in mind that programs can change the properties of controls at run time. Although this documentation is written as though the properties are set at design time using the Properties dialog for this control, there are many situations in which program code will be used to change a control's properties at run time.

Note: All properties and controls in the Tools toolbar are prefaced with "wl" to indicate they are the windowless lightweight versions of the controls and properties settings. The "wl" prefix is suppressed in the documentation below to enhance legibility.

Properties

In addition to the properties listed below, a Control tab provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

List box

General

MousePointer The type of mouse pointer displayed when over the list box. Choose from 16 different types plus a custom pointer

Appearance 3D or Flat. 3D is the standard Windows look. Flat results in a rectangular square of background color with a foreground color border.

MultiSelect Whether or not user can make multiple selections from the list box. NoMultiSelect means none. Simple, means a mouse click or SPACEBAR selects/deselects while arrow keys move focus. Extended adds CTRL and SHIFT click selection in the usual way.

OLEDragMode DragManual (default) or DragAutomatic. DragManual means the program handles all OLE drag/drop operations, while DragAutomatic means the list box handles all OLE drag/drop operations.

OLEDropMode Set to None (default) if the list box does not accept OLE drops and is to display the No Drop cursor if an OLE drop is attempted. Set to Manual, the list box will trigger OLE drop events, allowing programs to handle the OLE drop.
operation in code.

**Style** Standard or Checkbox. Checkbox adds little boxes that may be checked ON or OFF to select an item in the list.

**Enabled** True or False. True means the object can respond to user-generated events, false prevents it from responding. We can disable a control like a list box if we wish it to simply display information in a read-only way.

**Integral Height** True by default, so list resizes to show only complete items. False allows list size so partial items are visible.

**Sorted** True or False. True means to sort the list alphabetically.

**Columns** An integer number from 0 to n. 0 means no columns and the list box will scroll vertically. 1 to n means up to n columns and the list box will scroll horizontally through snaking columns as the columns are filled in with list items. If originally set non-zero, the number of columns may be changed at run time, but a zero setting at design time cannot be made non-zero at run time and vice versa.

**List**

**List** List items for this list box. Add an item by entering it and then pressing CTRL-ENTER to move focus to another line. Press Apply.

**ItemData** After adding a list item in the List pane and pressing Apply, a 0 value by default will be added to the ItemData pane for that item. Change this to whatever value is desired.

**Color**

**BackColor** Color to be used for the list box's background.

**ForeColor** Color to be used for the list box's foreground, the color of the text caption.

**Color Set** Choose from Standard Colors (standard Windows non-dithered colors) or Windows System Colors. The latter will be defined by the user's Control Panel settings and is normally the setting used so that the form changes appearance like the rest of Windows if the Control Panel settings are changed.

**Color Palette** Displays available colors. Click on the property to be changed to highlight it in the Properties pane, click on the desired color in the Color Palette pane and then press Apply.

**Edit Custom Color** Change the custom color presented in the Color Palette when the Color Set is set to Windows System Colors.

**Font**

**Properties** Font properties that may be changes.

**Font** Choose a font installed on this system. It's wise to choose standard Windows fonts such as MS Sans Serif that are universally available.

**Size** Size of font, in points.

**Effects** Bold, Italic, Underline or Strikeout.
Sample Text  A preview of the selected settings.
**Control - Combo Box**

Combo boxes combine the capabilities of a text box control and a list box control. Combo boxes allow the user to either enter text into the box or to choose one or more items from a list. If there are more items than will fit in the drop-down list, a scroll bar will be automatically added.

When a DropDownList Style is selected, the combo box becomes a list box that has a dropdown menu without the "combo" text box.

**To Add a Combo box to a Form**

1. Click on the Insert Combo box button in the Tools toolbar.
2. Click and drag the location and size where it is to be created in the form.
3. Continue to create any additional combo boxes desired.
4. Right click onto each combo box and choose Properties from the context menu.
5. Set the properties for the combo box as desired.
6. Move, resize and align the combo box as desired.

Properties normally both return and set that particular property. The easiest way to edit properties is through the context menu's properties dialog for that control.

Some attributes of controls, such as their size or position are properties not of the control but of the container for the control, in this case the Form itself. To change the size or position of controls we can simply click on them and resize or drag them to a new position.

Keep in mind that programs can change the properties of controls at run time. Although this documentation is written as though the properties are set at design time using the Properties dialog for this control, there are many situations in which program code will be used to change a control's properties at run time.

**Note:** All properties and controls in the Tools toolbar are prefaced with "wl" to indicate they are the windowless lightweight versions of the controls and properties settings. The "wl" prefix is suppressed in the documentation below to enhance legibility.

**Properties**

In addition to the properties listed below, a Control tab provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

**Combo box**

**General**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Text</strong></td>
<td>The initial text for the combo box.</td>
</tr>
<tr>
<td><strong>MousePointer</strong></td>
<td>The type of mouse pointer displayed when over the combo box. Choose from 16 different types plus a custom pointer</td>
</tr>
<tr>
<td><strong>Appearance</strong></td>
<td>3D or Flat. 3D is the standard Windows look. Flat results in a rectangular square of background color with a foreground color border.</td>
</tr>
<tr>
<td><strong>OLEDragMode</strong></td>
<td>DragManual (default) or DragAutomatic. DragManual means the program handles all OLE drag/drop operations, while DragAutomatic means the combo box handles all OLE drag/drop operations</td>
</tr>
<tr>
<td><strong>OLEDropMode</strong></td>
<td>Set to None (default) if the combo box does not accept OLE drops and is to display the No Drop cursor if an OLE drop is attempted. Set to Manual, the combo box will trigger OLE drop events, allowing programs to handle the OLE drop operation in code.</td>
</tr>
</tbody>
</table>
Style
- DropdownCombo: classic Windows combo box.
- SimpleCombo: a text box and a list that does not drop down. Must increase the height to see the list after creating the box. DropdownList: just the dropdown list portion without the editable text box.

Enabled
True or False. True means the object can respond to user-generated events, false prevents it from responding. We can disable a control like a combo box if we wish it to simply display information in a read-only way.

Integral Height
True by default, so list resizes to show only complete items. False allows list size so partial items are visible.

Locked
True or False. True means the user can scroll and highlight the text in the box but cannot change it. The program can change the text by modifying the text box's Text property. False (default) means users can edit the text in the box.

Sorted
True or False. True means to sort the list alphabetically.

List
- List: List items for this combo box. Add an item by entering it and then pressing CTRL-ENTER to move focus to another line. Press Apply.
- ItemData: After adding a list item in the List pane and pressing Apply, a 0 value by default will be added to the ItemData pane for that item. Change this to whatever value is desired.

Color
- Back Color: Color to be used for the combo box's background.
- Fore Color: Color to be used for the combo box's foreground, the color of the text caption.
- Color Set: Choose from Standard Colors (standard Windows non-dithered colors) or Windows System Colors. The latter will be defined by the user's Control Panel settings and is normally the setting used so that the form changes appearance like the rest of Windows if the Control Panel settings are changed.
- Color Palette: Displays available colors. Click on the property to be changed to highlight it in the Properties pane, click on the desired color in the Color Palette pane and then press Apply.
- Edit Custom Color: Change the custom color presented in the Color Palette when the Color Set is set to Windows System Colors.

Font
- Properties: Font properties that may be changes.
- Font: Choose a font installed on this system. It's wise to choose standard Windows fonts such as MS Sans Serif that are universally available.
- Size: Size of font, in points.
- Effects: Bold, Italic, Underline or Strikeout.
Sample Text  A preview of the selected settings.
Control - Horiz / Vert Scroll Bars

Scroll bars allow navigation through lists of many items or through large amounts of information. They are also used to scroll through pictures or otherwise move position or to change values in an apparently analog way.

To Add a Scroll bar to a Form

1. Click on the Insert Horizontal Scroll bar or Insert Vertical Scroll bar button in the Tools toolbar.
2. Click and drag the location and size where it is to be created in the form.
3. Continue to create any additional scroll bars desired.
4. Right click onto each scroll bar and choose Properties from the context menu.
5. Set the properties for the scroll bar as desired.
6. Move, resize and align the scroll bar as desired.

Properties normally both return and set that particular property. The easiest way to edit properties is through the context menu’s properties dialog for that control.

Some attributes of controls, such as their size or position are properties not of the control but of the container for the control, in this case the Form itself. To change the size or position of controls we can simply click on them and resize or drag them to a new position.

Keep in mind that programs can change the properties of controls at run time. Although this documentation is written as though the properties are set at design time using the Properties dialog for this control, there are many situations in which program code will be used to change a control's properties at run time.

Note: All properties and controls in the Tools toolbar are prefaced with "wl" to indicate they are the windowless lightweight versions of the controls and properties settings. The "wl" prefix is suppressed in the documentation below to enhance legibility.

Properties

In addition to the properties listed below, a Control tab provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

Scroll bar

General

MousePointer The type of mouse pointer displayed when over the scroll bar. Choose from 16 different types plus a custom pointer

Min Minimum value returned by the scroll bar, from zero (default).

Max Maximum value returned by the scroll bar, to 32767 (default).

SmallChange The amount of change in scroll bar value when user clicks on scroll arrow.

LargeChange The amount of change in scroll bar value when user clicks in region between the scroll box and scroll arrow.

Value Current position of the scroll bar, between Min and Max, inclusive.

Enabled True or False. True means the object can respond to user-generated events, false prevents it from responding. We can disable a control like a scroll bar if we wish it to simply display information in a read-only way.
Advanced Controls

Control - Tools (Advanced) Toolbar

The Tools (Advanced) toolbar is used with Forms to create frequently used Windows standard user interface controls that are technically more advanced or less frequently used than those in the Tools toolbar. The toolbar is enabled when a Form is the active window. Forms are used to provide user interfaces to scripts, to view tables and for other functions within Manifold.

Click on a control in the Tools (Advanced) toolbar and then click and drag in the Form window to insert the control in the form in the position and size indicated by the mouse click and drag. Forms are then customized using the properties for each control.

See the individual controls topics for details on each control. The individual control topics are the briefest summary of the control properties that appear in the Manifold dialogs and should be supplemented by reference to any one of the numerous commercial texts on use of standard Windows controls from VB.

Properties listed in the individual controls topics are only those properties that appear at design time in the Properties dialog. Advanced controls typically have other properties that are set or read at run time. Properties in advanced controls that are typical to Windows Common Controls are prefaced with "cc", suppressed in the following topics for greater legibility. Prefixes are obvious from inspection of the options in the Properties dialogs.

Tools (Advanced) Controls

<table>
<thead>
<tr>
<th>Insert Animation</th>
<th>Plays silent .avi files to create dialog effects like the sheet of paper that flies between folders in the Windows copy progress dialog. Can also play silent .avi files dropped onto the control. Manifold provides 19 cool Windows dialog .avi files to get started.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Insert Image List</td>
<td>Contains a collection of images that can be used by other Windows Common Controls such as ListView, TreeView, TabStrip and Toolbar controls, as well as with other controls with a Picture property. Saves development time by maintaining all images in a standard, consistent catalog of images.</td>
</tr>
<tr>
<td>Insert Image Combo Box</td>
<td>Similar to standard combo but with ability to include pictures with each item in the list portion of the combo, with special facilities for list management.</td>
</tr>
<tr>
<td>Insert Date / Time Picker</td>
<td>Displays date and/or time info and provides an interface for modifying date and time. Dropdown menu provides a MonthView calendar.</td>
</tr>
<tr>
<td>Insert Month View</td>
<td>An easy way to view and set date information using a monthly calendar. Can select one or multiple dates or show up to 12 months at a time.</td>
</tr>
<tr>
<td>Insert List View</td>
<td>Displays data as ListItem objects with an optional icon. Four different views provide data as icons, small icons, a list or a report. A sophisticated control.</td>
</tr>
<tr>
<td>Insert Progress Bar</td>
<td>Create a progress bar display that can be used to show the progress of a process.</td>
</tr>
</tbody>
</table>
| Insert Masked Text Box | Used to prompt users for input using a fixed format specified by a mask pattern, for example, a telephone number in a specified format. If a
mask pattern is not used, this control behaves about the same as a standard text box.

**Insert Rich Text Box** - Allows entry and editing of text using advanced formatting features, such as paragraph formatting with left and right indents, hanging indents, bold and italic font and so on. It also supports object embedding using the OLEObjects collection. Write your own word processor or create elaborate forms for users.

**Insert Slider** - Insert a slider bar control that can be moved left and right.

**Insert Tree View** - Insert a hierarchical tree display. Designed to display data such as organization trees, entries in an index, files and directories on disk, etc.

**Insert UpDown** - Insert an increment/decrement control, also called **spin buttons**.

**Insert Tab Strip** - Insert a tabbed control where clicking on each tab brings it to the fore.

**Insert Picture Clip** - Displays graphics from bitmap, icon, metafile, JPEG or GIF files.

**Insert Multimedia Control** - Manages Media Control Interface (MCI) devices like sound boards, MIDI sequencers, CD-ROM drives, audio players, videodisc players, etc. Add voice note recording to your dialog, or play spoken announcements.

**Insert Status Bar** - Insert a status bar like those at the bottom of many program windows. Complete with a nearly infinite set of properties for the intrepid programmer.

**Insert Tool Bar** - Insert a toolbar at the top of the form that hosts buttons or other controls. Yet another control with a vast array of properties.

**Insert Cool Bar** - Requires installation of Internet Explorer 3.0 or greater. Provides a modern, "railbar" look and the ability to create (get this!) **user configurable** toolbars like those in IE.

**Insert Common Dialog Control** - Provides a standard set of Windows dialog boxes for opening and saving files and selecting colors and fonts. Can also display Help.

**Insert System Info Control** - Detects system events such as desktop resizing, resolution changes, time changes. Also provides operating system platform and version information and changes in AC/battery power status and Plug/Play hardware configuration. Used when writing applications for portable devices (GIS in the field) and for developing info for your tech support team.

**Insert ActiveX Control** - Insert any ActiveX control available on this system.

**Other Controls**

Frequently used controls appear in the Tools toolbar for Form windows. Read the introductory topic before using those controls since they are implemented using a special, windowless technology that requires attention from the programmer.

**Form Properties for Controls**
Manifold adds an extra tab, the Control tab, to the usual tabs that appear in the design time properties dialog for controls. This tab provides access to the properties for this control maintained by the form. This extra tab will appear at design time for all controls. Although strictly speaking these are properties of the form that is the container for the control and not of the control, they are easiest to specify at design time if they appear within each control's properties dialog.

Control

<table>
<thead>
<tr>
<th>Name</th>
<th>The name used by the form to identify this control.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tag</td>
<td>A string available for free use by the programmer. Often used for comments.</td>
</tr>
<tr>
<td>Left</td>
<td>Left margin position of the control.</td>
</tr>
<tr>
<td>Top</td>
<td>Top margin position of the control.</td>
</tr>
<tr>
<td>Width</td>
<td>Width of the control.</td>
</tr>
<tr>
<td>Height</td>
<td>Height of the control.</td>
</tr>
<tr>
<td>Visible</td>
<td>Make this control visible or invisible.</td>
</tr>
</tbody>
</table>
Control - Animation

Plays silent .avi files to create dialog effects like the sheet of paper that flies between folders in the Windows copy progress dialog. Can also play silent .avi files dropped onto the control. Manifold provides 19 cool Windows dialog .avi files to get started.

Properties

In addition to the properties listed below, a Control tab provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

Animation

General

**OLEDropMode**
Set to None (default) if the animation does not accept OLE drops and is to display the No Drop cursor if an OLE drop is attempted. Set to Manual, the animation will trigger OLE drop events, allowing programs to handle the OLE drop operation in code.

**AutoPlay**
True - the .avi file plays automatically in a continuous loop once it is loaded into the control. False - Does not play until the Play method is used.

**Center**
True (Default) - Center the .avi within the control. False - position the .avi at 0,0.

**BackStyle**
Transparent (Default) - background color of the control is shown. Opaque - background color from the .avi fills the control and covers the control's background color.

Color

**Back Color**
Color to be used for the animation box background.

**Color Set**
Choose from Standard Colors (standard Windows non-dithered colors) or Windows System Colors. The latter will be defined by the user's Control Panel settings and is normally the setting used so that the form changes appearance like the rest of Windows if the Control Panel settings are changed.

**Color Palette**
Displays available colors. Click on the property to be changed to highlight it in the Properties pane, click on the desired color in the Color Palette pane and then press Apply.

**Edit Custom Color**
Change the custom color presented in the Color Palette when the Color Set is set to Windows System Colors.
Control - Chart

Displays a chart.
Control - Image List

Contains a collection of images that can be used by other Windows Common Controls such as ListView, TreeView, TabStrip and Toolbar controls, as well as with other controls with a Picture property. Saves development time by maintaining all images in a standard, consistent catalog of images.

ImageList can use bitmap (.bmp), cursor (.cur), icon (.ico), JPEG (.jpg) or GIF (.gif) files for images. We can add/remove images at design time or at run time using the standard collection object properties (Key and Index) and the standard methods (Add, Remove, Clear, etc).

Use ImageList to store images representing open/closed folders, documents, etc for use in a TreeView. These can be dynamically assigned to the TreeView nodes as it expands or collapses. ImageList is a good place to save frequently used iconic images such as file open/close/print images for toolbar buttons or MousePointer icons and DragIcons.

To Add Images at Design Time

1. Click Insert Picture in the control's Images property tab.
2. Use the resulting Select Picture dialog to find the desired image file and open it (multiple files may be opened).
3. In the Key box assign a unique string for each image.
4. If desired, optionally assign a Tag string for each image. Tag strings need not be unique.

Properties

In addition to the properties listed below, a Control tab provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

Command Button

General

16 x 16, 32 x 32, 48 x 48, Custom

Image sizes in this control. Must be specified before any images are added. The size of the first image is what is used for all images when feeding images to a Windows Common Control bound to this one.

Height, Width

Size of image to use when Custom size is enabled.

UseMaskColor

If checked, enables use of mask color in a. A mask color is the color that is to be made transparent.

Images

Index

Integer that uniquely identifies an image in the ImageList collection. Numbered in order of creation from the first image, which is always 1.

Key

A unique string that identifies each image.

Tag

Stores a string available for the programmer to use as desired. Often used to store an identification string of some sort.

Images

Previews of the images in the ListImage collection. Add with InsertPicture and remove with RemovePicture.

Image Count

…Gosh… What could this number be?
<table>
<thead>
<tr>
<th><strong>Back Color</strong></th>
<th>Color to be used for image's background, if any.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Mask Color</strong></td>
<td>Color to be treated as transparent in an image used when UseMaskColor is checked.</td>
</tr>
<tr>
<td><strong>Color Set</strong></td>
<td>Choose from Standard Colors (standard Windows non-dithered colors) or Windows System Colors. The latter will be defined by the user's Control Panel settings and is normally the setting used so that the form changes appearance like the rest of Windows if the Control Panel settings are changed.</td>
</tr>
<tr>
<td><strong>Color Palette</strong></td>
<td>Displays available colors. Click on the property to be changed to highlight it in the Properties pane, click on the desired color in the Color Palette pane and then press Apply.</td>
</tr>
<tr>
<td><strong>Edit Custom Color</strong></td>
<td>Change the custom color presented in the Color Palette when the Color Set is set to Windows System Colors.</td>
</tr>
</tbody>
</table>
Control - Image Combo Box

Similar to standard combo but with ability to include pictures with each item in the list portion of the combo, with special facilities for list management.

Combo boxes combine the capabilities of a text box control and a list box control. Combo boxes allow the user to either enter text into the box or to choose one or more items from a list. If there are more items than will fit in the drop-down list, a scroll bar will be automatically added. Image Combo boxes allow indentation of the items within them.

Image Combo boxes must be used in conjunction with an associated Image List control, which contains the images to be used for the Image Combo box’s items. Unlike regular combo boxes, which may be populated at design time using their List tab, an Image Combo box is populated with items programmatically at run time. Only the choice of which Image List is associated with the Image Combo box is made at design time.

To Add an Image Combo box to a Form

1. Click on the Insert Image Combo box button in the Tools toolbar.
2. Click and drag the location and size where it is to be created in the form.
3. Continue to create any additional combo boxes desired.
4. Right click onto each combo box and choose Properties from the context menu.
5. Set the properties for the combo box as desired.
6. Move, resize and align the combo box as desired.
7. Create and populate with images the Image List associated with this Image Combo.
8. Set the ImageList property to the associated Image List.
9. At run time, populate the Image Combo with items.

Properties

In addition to the properties listed below, a Control tab provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

Combo box

General

MousePointer The type of mouse pointer displayed when over the combo box. Choose from 16 different types plus a custom pointer.

ImageList Associated ImageList control.

OLEDragMode DragManual (default) or DragAutomatic. DragManual means the program handles all OLE drag/drop operations, while DragAutomatic means the combo box handles all OLE drag/drop operations.

OLERefMode Set to None (default) if the combo box does not accept OLE drops and is to display the No Drop cursor if an OLE drop is attempted. Set to Manual, the combo box will trigger OLE drop events, allowing programs to handle the OLE drop operation in code.

Indentation Starting indentation for items in the drop down list.

Text Initial text string for the box.

Enabled True or False. True means the object can respond to user-generated events, false prevents it from responding. We can disable a control like a combo box if we wish it to simply display information in a read-only way.

Locked True or False. True means the user can scroll and highlight the text in the box but cannot change it.
program can change the text by modifying the text box's **Text** property. False (default) means users can edit the text in the box.

### Color

**Back Color**  
Color to be used for the combo box's background.

**Fore Color**  
Color to be used for the combo box's foreground, the color of the text caption.

**Color Set**  
Choose from Standard Colors (standard Windows nondithered colors) or Windows System Colors. The latter will be defined by the user's Control Panel settings and is normally the setting used so that the form changes appearance like the rest of Windows if the Control Panel settings are changed.

**Color Palette**  
Displays available colors. Click on the property to be changed to highlight it in the **Properties** pane, click on the desired color in the **Color Palette** pane and then press **Apply**.

**Edit Custom Color**  
Change the custom color presented in the **Color Palette** when the **Color Set** is set to Windows System Colors.

### Font

**Properties**  
Font properties that may be changes.

**Font**  
Choose a font installed on this system. It's wise to choose standard Windows fonts such as **MS Sans Serif** that are universally available.

**Size**  
Size of font, in points.

**Effects**  
Bold, Italic, Underline or Strikeout.

**Sample Text**  
A preview of the selected settings.

### Picture

**MouseIcon**  
Custom icon to use when the **MousePointer** property is set to 99. Like Visual Basic, will not load animated cursor (.ani) files.
Control - Date / Time Picker

Displays date and/or time info and provides an interface for modifying date and time. Dropdown menu provides a MonthView calendar.

The UpDown property sets whether this control operates as a masked edit box for dates and times, or if it operates with a dropdown calendar. Setting UpDown true adds an UpDown control to the box and suppresses the calendar. Using the UpDown button will tab the focus between each part of the date and time mask for entry of that part of the date/time.

Properties

In addition to the properties listed below, a Control tab provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

DateTimePicker

General

Value  Date expression that is the default property of the control. Set a default date, if desired.

MinDate  Date expression setting lower boundary of the calendar.

MaxDate  Date expression setting upper boundary of the calendar.

Format  LongDate, ShortDate, Time or Custom.

MousePointer  The type of mouse pointer displayed when over the DateTimePicker. Choose from 16 different types plus a custom pointer

OLEDropMode  Set to None (default) if the DateTimePicker does not accept OLE drops and is to display the No Drop cursor if an OLE drop is attempted. Set to Manual, the DateTimePicker will trigger OLE drop events, allowing programs to handle the OLE drop operation in code.

CustomFormat  string setting forth custom format when Format is set to custom.

Enabled  True or False. True means the object can respond to user-generated events, false prevents it from responding.

CheckBox  False (Default) - Control always returns a date. True - A checkbox appears. If the user does not check this box, no date is returned. Handy for forms where requiring a date ("Due date?") is an option.

UpDown  True - UpDown control appears to change the date instead of a drop down calendar. False (Default) - Calendar appears. When True, switches mode to become a masked edit control.

Time  Sets Hour, Minute and Second properties.

Font

Properties  Font properties that may be changes.

Font  Choose a font installed on this system. It's wise to choose standard Windows fonts such as MS Sans Serif that are universally available.

Size  Size of font, in points. The size of the font sets the size of the drop down portion of this control.
Effects  Bold, Italic, Underline or Strikeout.

Sample Text  A preview of the selected settings.

**Color**

**CalendarBackColor**  Color to be used for the DateTimePicker's background.

**CalendarForeColor**  Color to be used for the DateTimePicker's foreground, the color of the text caption.

**CalendarTitleBack Color**  Customize calendar title background color.

**CalendarTitleFore Color**  Customize calendar title foreground color.

**CalendarTrailingForeColor**  Color of dates that preceded and follow the displayed month or months.

**Color Set**  Choose from Standard Colors (standard Windows non-dithered colors) or Windows System Colors. The latter will be defined by the user's Control Panel settings and is normally the setting used so that the form changes appearance like the rest of Windows if the Control Panel settings are changed.

**Color Palette**  Displays available colors. Click on the property to be changed to highlight it in the Properties pane, click on the desired color in the Color Palette pane and then press **Apply**.

**Edit Custom Color**  Change the custom color presented in the Color Palette when the **Color Set** is set to Windows System Colors.

**Picture**

**MouseIcon**  Custom icon to use when the MousePointer property is set to 99. Like Visual Basic, will not load animated cursor (.ani) files.

**Custom Date and Time Formats**

The **CustomFormat** property of the **DateTimePicker** allows specifying fully custom formats for dates and times that can intermingle regular text and the following special format characters within the mast string.

- **d**  One- or two-digit day.
- **dd**  Two-digit days with single digits prefixed with 0.
- **ddd**  Three-character abbreviated weekday.
- **dddd**  Full weekday name.
- **h**  One- or two-digit hour in 12-hour format.
- **hh**  Two-digit hour in 12-hour format with single digit hours prefixed with 0.
- **H**  One- or two digit hour in 24-hour format.
- **HH**  Two-digit hour in 24-hour format with single digit hours prefixed with 0.
- **m**  One- or two-digit minute.
- **mm**  Two-digit minutes with single digits prefixed with 0.
Manifold® System Release 8.00 User Manual

M  One- or two-digit month number.

MM  Two-digit month numbers with single digits prefixed with 0.

MMM  Three-character month name abbreviation.

MMMM  Full month name.

s  One- or two-digit second.

ss  Two-digit seconds with single digits prefixed with 0.

t  One-letter AM/PM abbreviation: either "A" or "P"

tt  Either "AM" or "PM"

X  A callback field. The control fills in all other fields and then asks the owner how to fill in the portion with "X" characters. Use different numbers of X's (like, XX or XXXX for different call back fields in the same mask string).

y  The last digit of the year.

yy  The last two digits of the year.

yyy  The full year.

Example:

"The date is 'ddddMMMMdd, yyy ' and the time is 'h:mtt"

Will result in dates such as:

"The date is Friday February 04, 2000 and the time is 3:34 PM"

Callbacks are used with format strings like “dddd XX ” to see what should be put in the XX based on what is in the dddd, for example to substitute the XX with a non-English day name in addition to the English name. If the dddd is "Wednesday" you could write the appropriate non-English name for the target audience. Consult a good VB reference text for use of callbacks with this control.

Notes

- More than one month may be displayed at a time by setting MonthRows and MonthColumns properties at run time.
- Determine which day of the week appears as the first day at run time by changing the value of the StartOfWeek property.
- Individual days can have their day number boldfaced at run time to emphasize holidays, etc.
Control - Month View

An easy way to view and set date information using monthly calendars. Can select one or multiple dates or show up to 12 months at a time.

Properties

In addition to the properties listed below, a Control tab provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

MonthView

General

**Value**
- Date expression that is the default property of the control. Set a default date, if desired.

**MinDate**
- Date expression setting lower boundary of the calendar.

**MaxDate**
- Date expression setting upper boundary of the calendar.

**StartOfWeek**
- Day of the week to use to start each week.

**MousePointer**
- The type of mouse pointer displayed when over the MonthView. Choose from 16 different types plus a custom pointer.

**OLEDropMode**
- Set to None (default) if the MonthView does not accept OLE drops and is to display the No Drop cursor if an OLE drop is attempted. Set to Manual, the MonthView will trigger OLE drop events, allowing programs to handle the OLE drop operation in code.

**BorderStyle**
- FixedSingle (default) or None. None may be used with Flat Appearance to achieve an uncaptioned rectangle of background color.

**Appearance**
- 3D or Flat. 3D is the standard Windows look. Flat results in a rectangular square of background color with a foreground color border.

**ShowWeekNumbers**
- Show week number (week position in year) along left column border.

**MultiSelect**
- Whether or not user can make multiple selections from the MonthView.

**Enabled**
- True or False. True means the object can respond to user-generated events, false prevents it from responding.

**ShowToday**
- True to show “Today is” date line at bottom of calendar.

**MonthRows**
- How many rows to use to show multiple months.

**MonthColumns**
- How many columns to use to show multiple months.

**ScrollRate**
- The number of months that are scrolled when user clicks a month scroll button. Allows scrolling of more than one month at a time, so if four months are displayed an even four months at a time can be scrolled.

**MaxSelCount**
- Valid when MultiSelect is True. Sets the maximum number of contiguous days that can be selected at once.

Font

Properties
- Font properties that may be changes.
Font  Choose a font installed on this system. It's wise to choose standard Windows fonts such as **MS Sans Serif** that are universally available.

Size  Size of font, in points. The size of the font sets the size of the drop down portion of this control.

Effects  Bold, Italic, Underline or Strikeout.

Sample Text  A preview of the selected settings.

**Color**

BackColor  Color to be used for the MonthView's background.

ForeColor  Color to be used for the MonthView's foreground, the color of the text caption.

MonthBackColor  Background color for months.

TitleBackColor  Customize calendar title background color.

TitleForeColor  Customize calendar title foreground color.

TrailingForeColor  Color of dates that preceded and follow the displayed month or months.

Color Set  Choose from Standard Colors (standard Windows non-dithered colors) or Windows System Colors. The latter will be defined by the user's Control Panel settings and is normally the setting used so that the form changes appearance like the rest of Windows if the Control Panel settings are changed.

Color Palette  Displays available colors. Click on the property to be changed to highlight it in the Properties pane, click on the desired color in the Color Palette pane and then press Apply.

Edit Custom Color  Change the custom color presented in the Color Palette when the Color Set is set to Windows System Colors.

**Picture**

MouseIcon  Custom icon to use when the MousePointer property is set to 99. Like Visual Basic, will not load animated cursor (.ani) files.

**Custom Date and Time Formats**

The CustomFormat property of the MonthView allows specifying fully custom formats for dates and times that can intermingle regular text and the following special format characters within the mast string.

- **d**  One- or two-digit day.
- **dd**  Two-digit days with single digits prefixed with 0.
- **ddd**  Three-character abbreviated weekday.
- **dddd**  Full weekday name.
- **h**  One- or two-digit hour in 12-hour format.
- **hh**  Two-digit hour in 12-hour format with single digit hours prefixed with 0.
H  One- or two digit hour in 24-hour format.
HH  Two-digit hour in 24-hour format with single digit hours prefixed with 0.
m  One- or two-digit minute.
mm  Two-digit minutes with single digits prefixed with 0.
M  One- or two-digit month number.
MM  Two-digit month numbers with single digits prefixed with 0.
MMM  Three-character month name abbreviation.
MMMM  Full month name.
s  One- or two-digit second.
ss  Two-digit seconds with single digits prefixed with 0.
t  One-letter AM/PM abbreviation: either "A" or "P"
tt  Either "AM" or "PM"
X  A callback field. The control fills in all other fields and then asks the owner how to fill in the portion with "X" characters. Use different numbers of X's (like, XX or XXXX for different call back fields in the same mask string).
y  The last digit of the year.
yy  The last two digits of the year.
yyy  The full year.

**Example:**

"'The date is 'ddddMMMMdd, yyy ' and the time is 'h:mtt"

Will result in dates such as:

"The date is Friday February 04, 2000 and the time is 3:34 PM"

Callbacks are used with format strings like "dddd XX " to see what should be put in the XX based on what is in the dddd, for example to substitute the XX with a non-English day name in addition to the English name. If the dddd is "Wednesday" you could write the appropriate non-English name for the target audience. Consult a good VB reference text for use of callbacks with this control.

**Note:** Individual days can have their day number boldfaced at run time to emphasize holidays, etc.
Control - List View

Displays data as ListItem objects with an optional icon. Four different views provide data as icons, small icons, a list or a report. Can show data in columns with or without column heads. A very sophisticated control.

Note: Non-Common Control properties are prefaced with "lvw", suppressed in the following for greater legibility.

Properties

In addition to the properties listed below, a Control tab provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

List View

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MousePointer</td>
<td>The type of mouse pointer displayed when over the list view. Choose from 16 different types plus a custom pointer</td>
</tr>
<tr>
<td>View</td>
<td>Style of display for each item: Icon - Full size icon and text label. SmallIcon - small icon and text label arranged horizontally. List - small icon and text label arranged vertically in columns. Report - small icons and text labels arranged in columns with additional info columns as desired.</td>
</tr>
<tr>
<td>Arrange</td>
<td>None, AutoLeft, AutoTop: Left and top align items along the left side or top of the control.</td>
</tr>
<tr>
<td>LabelEdit</td>
<td>Automatic - BeforeLabelEdit event is generated when the user clicks the label of a selected node. Manual - BeforeLabelEdit event generated only when the StartLabelEdit method is invoked.</td>
</tr>
<tr>
<td>BorderStyle</td>
<td>FixedSingle (default) or None. None may be used with Flat Appearance to achieve an uncaptioned rectangle of background color.</td>
</tr>
<tr>
<td>Appearance</td>
<td>3D or Flat. 3D is the standard Windows look. Flat results in a rectangular square of background color with a foreground color border.</td>
</tr>
<tr>
<td>OLEDragMode</td>
<td>DragManual (default) or DragAutomatic. DragManual means the program handles all OLE drag/drop operations, while DragAutomatic means the list view handles all OLE drag/drop operations</td>
</tr>
<tr>
<td>OLEDropMode</td>
<td>Set to None (default) if the list view does not accept OLE drops and is to display the No Drop cursor if an OLE drop is attempted. Set to Manual, the list view will trigger OLE drop events, allowing programs to handle the OLE drop operation in code.</td>
</tr>
<tr>
<td>HideColumnHeaders</td>
<td>False (default) - Column headers are visible. True - column headers are hidden.</td>
</tr>
<tr>
<td>HideSelection</td>
<td>True or False. True means that highlighted text will not appear highlighted when the list view loses the focus. False means that highlighted text stays highlighted even when another form or dialog has the focus.</td>
</tr>
<tr>
<td>LabelWrap</td>
<td>True (Default) - labels wrap. False - labels don't wrap.</td>
</tr>
<tr>
<td>MultiSelect</td>
<td>Whether or not user can make multiple selections from the list view. NoMultiSelect means none. Simple, means a mouse click or SPACEBAR selects/deselects while arrow keys move focus. Extended adds CTRL and SHIFT click selection in the usual way.</td>

<td>Enabled</td>
<td>True or False. True means the object can respond to user-</td>
</tr>
</tbody>
</table>
generated events, false prevents it from responding. We can disable a control like a list view if we wish it to simply display information in a read-only way.

**AllowColumnReorder**
- False (Default) - User cannot reorder columns.
- True - Users can reorder columns.

**Checkboxes**
- False (Default) - Checkboxes do not appear.
- True - Checkboxes appear.

**FlatScrollbar**
- False (Default) - Standard scrollbars appear.
- True - FlatScrollBar style scrollbars appear.

**FullScreenSelect**
- Specifies if the entire row is selected. Valid only when View is set to Report.

**Gridlines**
- Specifies if gridlines appear when View is set to Report.
- False (Default) - No gridlines.
- True - Display gridlines.

**HotTracking**
- Whether or not mouse-sensitive highlighting is enabled.
- True - Header captions are highlighted as the mouse passes over them.
- False - HeaderItem objects do not respond to mouse movement unless the mouse button is clicked.

**HoverSelection**
- Whether or not a ListItem object is select on a mouse hover.
- False (Default) - No selection when the mouse hovers over an item.
- True - Item is selected on mouse hover.

**Image Lists**
- **Normal** ImageList to use for images of standard sized icons.
- **Small** ImageList to use for small icons.
- **Column Header** ImageList to use for images in column headers.

**Sorting**
- **Sorted** True - Items are sorted according to the SortOrder property.
- False - Items are not sorted.

**SortKey** A positive integer or zero.
- 0 - Sort using the ListItem object’s Text property.
- >=1 - Sort using subitem whose collection index is specified here.

**SortOrder** Ascending - From beginning of alphabet, earliest date or lowest number.
- Descending - The other way.

**Column Headers**
- **Index** Uniquely identifies the column. If changing columns dynamically, use the Key since the index might change. Begins with 1.

**Insert/Remove Column** Add or remove columns at design time.

**Text** Caption for this column.

**Alignment**
- Left - Text in columns is aligned left.
- Right - Text aligned right.
- Center - Text is centered.

**Width** Width of this column.

**Key** A unique string that identifies each column.
Tag
Stores a string available for the programmer to use as desired. Often used to store an identification or description string of some sort.

Icon Index
Which image to use in the Column Header ImageList to use for this column. Begins with 0.

Color

Back Color
Color to be used for the list view's background.

Fore Color
Color to be used for the list view's foreground, the color of the text caption.

Color Set
Choose from Standard Colors (standard Windows non-dithered colors) or Windows System Colors. The latter will be defined by the user's Control Panel settings and is normally the setting used so that the form changes appearance like the rest of Windows if the Control Panel settings are changed.

Color Palette
Displays available colors. Click on the property to be changed to highlight it in the Properties pane, click on the desired color in the Color Palette pane and then press Apply.

Edit Custom Color
Change the custom color presented in the Color Palette when the Color Set is set to Windows System Colors.

Font

Properties
Font properties that may be changes.

Font
Choose a font installed on this system. It's wise to choose standard Windows fonts such as MS Sans Serif that are universally available.

Size
Size of font, in points.

Effects
Bold, Italic, Underline or Strikeout.

Sample Text
A preview of the selected settings.

Picture

MouselIcon
Custom icon to use when the MousePointer property is set to 99. Like Visual Basic, will not load animated cursor (.ani) files.

Picture
Graphic to show on an enabled control.

Note: graphics are loaded at design time and saved within the project. When browsing to find the graphic to be used, .bmp, .ico, .wmf, .gif or .jpeg files may be used.
Control - Progress Bar

Create a progress bar display that can be used to show the progress of a process.

Properties

In addition to the properties listed below, a Control tab provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

Progress bar

General

Min Minimum value returned by the progress bar, from zero (default).

Max Maximum value returned by the progress bar, typically to 100 (default).

MousePointer The type of mouse pointer displayed when over the progress bar. Choose from 16 different types plus a custom pointer

BorderStyle FixedSingle (default) or None. None may be used with Flat Appearance to achieve an uncaptioned rectangle of background color.

Appearance 3D or Flat. 3D is the standard Windows look. Flat results in a rectangular square of background color with a foreground color border.

OLEDropMode Set to None (default) if the progress bar does not accept OLE drops and is to display the No Drop cursor if an OLE drop is attempted. Set to Manual, the progress bar will trigger OLE drop events, allowing programs to handle the OLE drop operation in code.

Orientation Horizontal (Default) or Vertical progress bar.

Scrolling Standard - Progress bar grows in chunks in the usual way. Make the progress bar at least 12 times wider than it is high for a reasonable effect. Smooth - A solid bar that grows smoothly.

Enabled True or False. True means the object can respond to user-generated events, false prevents it from responding. We can disable a control like a progress bar if we wish it to simply display information in a read-only way.

Picture

MouseIcon Custom icon to use when the MousePointer property is set to 99. Like Visual Basic, will not load animated cursor (.ani) files.

Tips

Set the Visible property to False to hide the progress bar until the process on which it reports agonizingly slow progress begins, and then set the Visible property to True to show the progress bar. When it is done, set the Visible property to False again.

Big fun: the progress bar displays whatever the Value is so you can make it run backwards by decrementing Value at regular intervals. Use this capability with restraint, as it is not good karma to play with people's minds by having progress bars go back and forth. Backward running progress bars are sometimes used to show de-installation or file removal progress.
Control - Masked Text Box

Used to prompt users for input using a fixed format specified by a mask pattern, for example, a telephone number in a specified format. If a mask pattern is not used, this control behaves about the same as a standard text box.

Note: Non-Common Control properties are prefaced with "msk", suppressed in the following for greater legibility.

Properties

In addition to the properties listed below, a Control tab provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

Masked Edit box

General

AutoTab Whether or not the next control in the tab order receives the focus as soon as the Text property of the Masked Edit box is filled with valid data. False (Default) - AutoTab is not on. A ValidationError event occurs if more characters are entered than allowed by the input mask. True - AutoTab is on and the focus moves immediately to the next control, which then receives any extra characters entered.

PromptInclude Whether the Text property contains the prompt character. True (Default) - Text contains prompt characters, if any. False - Text property does not contain prompt characters.

HideSelection True or False. True means that highlighted text will not appear highlighted when the masked edit box loses the focus. False means that highlighted text stays highlighted even when another form or dialog has the focus.

Enabled True or False. True means the object can respond to user-generated events, false prevents it from responding.

AllowPrompt Determines if prompt character is a valid input character. False (Default) - Prompt character is not a valid input character. True - Prompt character is a valid input.

Mask Enter literal characters to be used as a mask, or choose from presets in the Format box.

Format Choose from a set of predefined formats to specify how the data in the MaskedEdit box displays and prints. Can be different than the input mask (weird!).

MousePointer The type of mouse pointer displayed when over the masked edit box. Choose from 16 different types plus a custom pointer.

BorderStyle FixedSingle (default) or None. None may be used with Flat Appearance to achieve an uncaptioned rectangle of background color.

ClipMode Whether or not literal characters are included when doing a cut or copy command. True will limit copy operations to only data entered by the user, without literals.

OLEDragMode DragManual (default) or DragAutomatic. DragManual means the program handles all OLE drag/drop operations, while DragAutomatic means the masked edit box handles all OLE drag/drop operations.

OLEDropMode Set to None (default) if the masked edit box does not accept OLE drops and is to display the No Drop cursor if an OLE drop is attempted. Set to Manual, the masked edit box will trigger OLE drop events, allowing programs...
to handle the OLE drop operation in code.

**MaxLength**  From 1 to 64. A mask field can have up to 64 characters.

**PromptChar**  The character to use for prompting users, almost always an underscore character.

### Color

**Back Color**  Color to be used for the masked edit box's background.

**Fore Color**  Color to be used for the masked edit box's foreground, the color of the text caption.

**Color Set**  Choose from Standard Colors (standard Windows non-dithered colors) or Windows System Colors. The latter will be defined by the user's Control Panel settings and is normally the setting used so that the form changes appearance like the rest of Windows if the Control Panel settings are changed.

**Color Palette**  Displays available colors. Click on the property to be changed to highlight it in the Properties pane, click on the desired color in the Color Palette pane and then press **Apply**.

**Edit Custom Color**  Change the custom color presented in the Color Palette when the Color Set is set to Windows System Colors.

### Font

**Properties**  Font properties that may be changes.

**Font**  Choose a font installed on this system. It's wise to choose standard Windows fonts such as **MS Sans Serif** that are universally available.

**Size**  Size of font, in points.

**Effects**  Bold, Italic, Underline or Strikeout.

**Sample Text**  A preview of the selected settings.

### Picture

**MouseIcon**  Custom icon to use when the MousePointer property is set to 99. Like Visual Basic, will not load animated cursor (.ani) files.

### Masks

Each character position in the input mask maps to a placeholder of a specified type or to a literal character. For example, a (###) mask has two literal characters () surrounding three digit placeholder characters, the #. As the user enters data the insertion point will automatically skip over literals to the next placeholder position indicated by the prompt character.

**Mask Characters**

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#  Digit placeholder.</td>
</tr>
<tr>
<td>.  Decimal placeholder. Actual character shown will be</td>
</tr>
</tbody>
</table>
substituted (, or .) based on international settings.

, Thousands placeholder. Actual character shown will be substituted (, or .) based on international settings.

: Time separator. Actual character shown will be substituted based on international settings.

/ Date separator. Actual character shown will be substituted based on international settings.

\ Treat next character as a literal. Allows use of placeholder characters as literals. Treated as a literal for masking purposes.

& Character placeholder. ANSI characters from 32-126 and from 128-255.

> Convert all characters that follow to uppercase.

< Convert all characters that follow to lowercase.

A Required alphanumeric character placeholder.

a Optional alphanumeric character placeholder.

9 Optional digit character placeholder.

C Optional character or space placeholder.

? Letter placeholder.

[Literal] All other characters are displayed as themselves as literals.

Format Property

The Format property modifies how the MaskedEdit control displays and prints using standard formats for numbers, currency and date/time data.

<table>
<thead>
<tr>
<th>Format Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Empty)</td>
<td>Default numeric format. Displays as entered.</td>
</tr>
<tr>
<td>$#,##0.00;($#,##0.00)</td>
<td>Currency format using thousands separator with negative numbers in parentheses.</td>
</tr>
<tr>
<td>0</td>
<td>Fixed number format displaying at least one digit.</td>
</tr>
<tr>
<td>#,##0</td>
<td>Commas format using commas as thousands separator.</td>
</tr>
<tr>
<td>0%</td>
<td>Percent format. Multiply Value by 100 and append a percent sign.</td>
</tr>
<tr>
<td>0.00E+00</td>
<td>Scientific notation.</td>
</tr>
<tr>
<td>c</td>
<td>Default general date and time format. Display date, time or both.</td>
</tr>
<tr>
<td>ddddd</td>
<td>Long date format taken from International setting of Control Panel.</td>
</tr>
<tr>
<td>dd-mmm-yy</td>
<td>Medium date format.</td>
</tr>
<tr>
<td>ddddd</td>
<td>Short date format taken from International setting of Control Panel.</td>
</tr>
</tbody>
</table>
Long time format taken from International setting of Control Panel.

Medium time format.

Short time format.

Tips

The MaskedEdit control is a bound control, so it can be linked to a data control and thus display field values for the current record in a data set. It can also write values to a data set. Use the three bound properties of MaskedEdit to do this: DataChanged, DataField and DataSource. See your favorite reference on the ADO Data Control for more info on such uses.
Control - Rich Text Box

Allows entry and editing of text using advanced formatting features, such as paragraph formatting with left and right indents, hanging indents, bold and italic font and so on. Also supports object embedding using the OLEObjects collection.

RichTextBox does not have the 64K character limit of ordinary TextBox controls, plus it also handles drag and drop from both the clipboard and OLE with mouse button behavior like Microsoft Word. In just a few weekends of work, you too can write your very own word processor using this control in a Manifold script.

This control has a large number of run time properties that do not appear in the Properties dialog. These are listed in this topic together with a summary list of methods to show the great range covered by a "big" control. They should be used based on guidance from a comprehensive text on Visual Basic programming that includes a detailed reference for this control.

Note: Non-Common Control properties are prefaced with "rtf", suppressed in the following for greater legibility.

Properties

In addition to the properties listed below, a Control tab provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

RichTextBox

General

FileName [load from] The filename of the .txt or .rtf file loaded into the rich text box.

OLEDragMode DragManual (default) or DragAutomatic. DragManual means the program handles all OLE drag/drop operations, while DragAutomatic means the rich text box handles all OLE drag/drop operations.

OLEDropMode Set to None (default) if the rich text box does not accept OLE drops and is to display the No Drop cursor if an OLE drop is attempted. Set to Manual, the rich text box will trigger OLE drop events, allowing programs to handle the OLE drop operation in code.

RightMargin An integer specifying the indent in twips from the right edge of the text to the right edge of the control. Used for text wrapping, centering and indentation. Default 0 wraps to rightmost part of the control. Take into account border widths if using FixedSingle is set in BorderStyle.

MaxLength Long integer specifying the maximum number of characters a user can enter. Default is zero, indicating no maximum.

BulletIndent If SetBullet is True, indicates the amount of indent in dialog based units. Will return NULL if the selection spans multiple paragraphs with different margin settings.

AutoVerbMenu Determines if a pop-up menu containing a selected object's verbs is displayed when the user right-clicks an OLE object. True - Menu displayed. False - No menu. When True, Click and MouseDown events won't occur when the OLE object is right clicked.

Enabled True or False. True means the object can respond to user-generated events, false prevents it from responding. We can disable a control like a rich text box if we wish it to simply display information in a read-only way.

Locked True or False. True means the user can scroll and highlight the text in the box but cannot change it. The

program can change the text by modifying the rich text box's **Text** property. False (default) means users can edit the text in the rich text box.

**MultiLine** True or False. True (checked) enables multiple lines of text. A multiple line rich text box will wrap text as the user enters text that extends past the rich text box. If a horizontal scroll bar is present text will not wrap. On a form with no default button, pressing ENTER in a multiple line rich text box will move the focus to the next line. If a default button exists in the form, the user must press CTRL Enter to move to the next line.

**HideSelection** True or False. True means that highlighted text will not appear highlighted when the rich text box loses the focus. False means that highlighted text stays highlighted even when another form or dialog has the focus.

**Appearance**

**Appearance** 3D or Flat. 3D is the standard Windows look. Flat results in a rectangular square of background color with a foreground color border.

**BorderStyle** FixedSingle (default) or None. None may be used with Flat **Appearance** to achieve an uncaptioned rectangle of background color.

**MousePointer** The type of mouse pointer displayed when over the rich text box. Choose from 16 different types plus a custom pointer.

**ScrollBars** NoScrollbars, Horizontal, Vertical or Both. Set as desired to cause scroll bars to appear. Scroll bars appear only if **MultiLine** is set True (checked). Scroll bars will always appear in rich text boxes if enabled by this property even if the text does not extend beyond the borders of the box.

**DisableNoScroll** Determines if scroll bars are disabled. False (Default) - Scroll bars appear normally when displayed. True - scroll bars appear dimmed when displayed and are not enabled. Ignored when ScrollBars property is set to zero, and otherwise scroll bars appear dimmed when lines are too short or lines too few to require scrolling.

**Color**

**Back Color** Color to be used for the rich text box's background.

**Color Set** Choose from Standard Colors (standard Windows non-dithered colors) or Windows System Colors. The latter will be defined by the user's Control Panel settings and is normally the setting used so that the form changes appearance like the rest of Windows if the Control Panel settings are changed.

**Color Palette** Displays available colors. Click on the property to be changed to highlight it in the **Properties** pane, click on the desired color in the **Color Palette** pane and then press **Apply**.

**Edit Custom Color** Change the custom color presented in the **Color Palette** when the **Color Set** is set to Windows System Colors.

**Font**
Properties
Font properties that may be changes.

Font
Choose a font installed on this system. It's wise to choose standard Windows fonts such as MS Sans Serif that are universally available.

Size
Size of font, in points.

Effects
Bold, Italic, Underline or Strikeout.

Sample Text
A preview of the selected settings.

Picture

Mouselcon
Custom icon to use when the MousePointer property is set to 99. Like Visual Basic, will not load animated cursor (.ani) files.

Note: The RichTextBox is a data-bound control, so we can bind it with a Data control to a large capacity field in a database system (for example, a TEXT type field in SQL Server or a Binary or Memo field in Access).

Properties
Following is a listing of properties for the RichTextBox control that may be used at run time. We can exploit these properties to create a full-power, professional word processor if so desired.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SelHangingIndent</td>
<td>Return or set integer margins for the paragraph(s).</td>
</tr>
<tr>
<td>SelIndent</td>
<td></td>
</tr>
<tr>
<td>SelRightIndent</td>
<td></td>
</tr>
<tr>
<td>SelAlignment</td>
<td>Controls alignment of paragraph(s). rtfLeft, rtfRight, rtfCenter or Null (current selection spans paragraphs with different alignments).</td>
</tr>
<tr>
<td>SelBold</td>
<td>Return or set font style of currently selected text. False (Default) - None of the characters in the selection or character following the insertion point have the font style. True - All characters have the font style. Null - A mix of font styles.</td>
</tr>
<tr>
<td>SelItalic</td>
<td></td>
</tr>
<tr>
<td>SelStrikethur</td>
<td></td>
</tr>
<tr>
<td>SelUnderline</td>
<td></td>
</tr>
<tr>
<td>SelCharOffset</td>
<td>Integer: Whether character(s) are on the normal text baseline. 0 - character(s) all are on baseline. Null - mix of offsets. &gt; 0 - Superscript above the baseline by given number in twips. &lt; 0 - Subscript below the baseline by given number in twips.</td>
</tr>
<tr>
<td>SelColor</td>
<td>Returns or sets value that determines color of selected text. The value specifies RGB colors in code using RGB or QBColor functions, or System color constants. Null - a mix of colors in selected text.</td>
</tr>
<tr>
<td>SelFontName</td>
<td>Returns or sets font for currently selected text or character(s) immediately following insertion point, using a string that identifies a font installed on the the system.</td>
</tr>
</tbody>
</table>
system. Returns Null if text contains a mix of fonts.

SelFontSize
Returns or sets font size for currently selected text or character(s) immediately following insertion point, using an integer for font size in points up to 2160. Returns Null if text contains a mix of sizes.

Set the SelFontName first, then the size and style.

SelBullet
Returns or sets value (integer or constant) determining bullet style of paragraph containing current selection or insertion point. False (Default) - paragraph(s) don’t have the bullet style. True - paragraph(s) have bullet style. Null - paragraph(s) have a mix of bullet and non-bullet styles.

SelTabCount
The number of tab positions in the selected paragraph(s) or in those paragraph(s) following insertion point.

SelTabs(index)
Returns or sets location for a designated tab, where index is an integer beginning at zero that identifies a specific tab. Location is an integer in dialog units.

SelRTF
Returns or sets the text string (in .rtf format) in the current selection. Returns zero length string if no text selected. Used with Print function to write .rtf files.

TextRTF
Returns or sets text in a RichTextBox control, including all .rtf code. Setting this property replaces entire contents with the new string. Used with Print function to write .rtf files.

SelProtected
Determines if current selection is protected. True - All characters are protected. False - None are protected. Null - A mix of protected/unprotected characters in the selection.

Protected text cannot be modified by the user. Used to create forms including areas of fixed text.

OLEObjects
Returns a reference to the OLEObjects collection.

DataMember
Returns or sets a specified data member from those offered by the data provider.

DataFormat
Returns or sets the StdDataFormat object to which a bound object is attached. [Available at design time.]

DataBindings
Returns DataBindings collection object containing the bindable properties available to the programmer.

TabIndex
Returns or sets the tab order of objects within the Form.

DragIcon
Returns or sets icon to be used as the pointer in a drag and drop operation.

DragMode
0 - Set VbManual (default) drag and drop mode. Requires using Drag method to initiate a drag and drop. 1 - Set VbAutomatic mode to automatically initiate a drag and drop.

CausesValidation
Determines whether Validation event will occur on a second control from which the focus is being shifted. True (Default) - control from which focus shifts causes Validate event. False - control will not cause its Validate event.

TabStop
Whether the user can use the TAB key to move focus. True (Default) - designates object as a tab stop. False - bypasses the object when user is tabbing.

HelpContextID
Returns or sets positive integer specifying the context number of the Help topic for this object. 0 (Default) -
no context number specified. You will be writing context-sensitive Help for your Manifold script dialogs... right?

<table>
<thead>
<tr>
<th>Name</th>
<th>Returns the name used in code to identify this control.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parent</td>
<td>Returns the Form that contains this control.</td>
</tr>
<tr>
<td>Font</td>
<td>Returns a Font object. Used to identify a specific Font object whose properties we wish to use.</td>
</tr>
<tr>
<td>Container</td>
<td>Always returns the Form, since there are no other containers available in Manifold script forms.</td>
</tr>
<tr>
<td>ToolTipText</td>
<td>Returns or sets the string to use as a tool tip for this control. Dynamically modified tool tips, anyone?</td>
</tr>
<tr>
<td>DataChanged</td>
<td>Indicates if data in this bound control has been changed by some process other than retrieving data from the current record. False (Default) - data currently in the control, if any, is the same as in the current record. True - it's not.</td>
</tr>
<tr>
<td>DataField</td>
<td>The name of a field to which this data consumer is bound.</td>
</tr>
<tr>
<td>DataSource</td>
<td>The data source through which this data consumer is bound to a database.</td>
</tr>
<tr>
<td>WhatsThisHelpID</td>
<td>An integer for the context number of context-sensitive Help for Windows '95 pop-up help.</td>
</tr>
<tr>
<td>SelLength</td>
<td>The number of characters selected.</td>
</tr>
<tr>
<td>SelStart</td>
<td>An index, the starting point of text selected or the position of the insertion point of no text selected.</td>
</tr>
<tr>
<td>SelText</td>
<td>A string containing the currently selected text or zero length string if no text selected.</td>
</tr>
<tr>
<td>Text</td>
<td>A string containing the text in the RichTextBox.</td>
</tr>
<tr>
<td>Index</td>
<td>A number that uniquely identifies this object.</td>
</tr>
<tr>
<td>Tag</td>
<td>A string that stores any extra data we like about our object.</td>
</tr>
<tr>
<td>Visible</td>
<td>True (Default) - this object is visible. False - this object is hidden.</td>
</tr>
<tr>
<td>Object</td>
<td>Returns the object, object's property or object's method. Used to specify an object we want to use in an Automation task.</td>
</tr>
</tbody>
</table>

Methods

Following is a short summary of methods available with the RichTextBox control.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Find</strong></td>
<td>Searches the text for a given string using one or more options, as follow.</td>
</tr>
<tr>
<td>string, start, end, options</td>
<td>rtfWholeWord&lt;br&gt;rtfMatchCase</td>
</tr>
</tbody>
</table>

2477
rtfNoHighlight

**GetLineFromChar**

Parameters:
- `charpos`: long integer character position index number.

Returns number of the line containing a specified long integer character position index number.

**LoadFile**

Parameters:
- `pathname`: string
- `filetype`: string

Loads a file using following file types:
- `rtfRTF`
- `rtfText`

**SaveFile**

Parameters:
- `pathname`: string
- `filetype`: string

Saves contents to a file using following file types:
- `rtfRTF`
- `rtfText`

**SelPrint**

Parameters:
- `hdc`: device context

Sends formatted text to a device for printing using the device context for the target printing device.

Example:

```vbnet
RichTextBox1.SelPrint(Printer.hDC)
```

**Span**

Parameters:
- `characterset`: string
- `forward`: boolean
- `negate`: boolean

Select text based on specified characterset.

**Upto**

Parameters:
- `characterset`: string
- `forward`: boolean
- `negate`: boolean

Moves the insertion point up to but not including the first character that is a member of the specified characterset.

**SetFocus**

Moves the focus to the specified form or control.

**Drag**

Parameters:
- `action`: string

Begins, ends or cancels a drag operation using optional action as follows:
- `vbCancel`
- `vbBeginDrag`
- `vbEndDrag`

**Move**

Parameters:
- `left`, `top`, `width`, `height`: numeric

Moves the control. Only the left argument is required.

**ZOrder**

Parameters:
- `position`: numeric

Moves the control's position relative to other instances of the same control in z-order.

**ShowWhatsThis**

Displays a selected topic in a help file using the
What's This Windows '95 popup help.

**OLEDrag** Initiates an OLE drag/drop operation.

**Refresh** Forces a complete repaint of the control.
**Control - Slider**

Insert a slider bar control that can be moved left and right. Adjust the slider by dragging it or by clicking on either side of the slider. Tick marks are optional, and the slider may be oriented horizontally or vertically.

**Note:** Non-Common Control properties are prefaced with "slid", suppressed in the following for greater legibility.

In addition to the properties listed below, a **Control tab** provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

## Slider

### General

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Min</strong></td>
<td>Minimum value returned by the slider, from zero (default).</td>
</tr>
<tr>
<td><strong>Max</strong></td>
<td>Maximum value returned by the slider, typically to 10 (default) or 100.</td>
</tr>
<tr>
<td><strong>SmallChange</strong></td>
<td>The amount of change in slider value when user presses left or right arrow keys on the keyboard.</td>
</tr>
<tr>
<td><strong>LargeChange</strong></td>
<td>The amount of change in slider value when user clicks to either side of slider handle, or when user presses Page Up or Page Down on keyboard.</td>
</tr>
<tr>
<td><strong>OLEDropMode</strong></td>
<td>Set to None (default) if the slider does not accept OLE drops and is to display the No Drop cursor if an OLE drop is attempted. Set to Manual, the slider will trigger OLE drop events, allowing programs to handle the OLE drop operation in code.</td>
</tr>
<tr>
<td><strong>Enabled</strong></td>
<td>True or False. True means the object can respond to user-generated events, false prevents it from responding.</td>
</tr>
<tr>
<td><strong>SelectRange</strong></td>
<td>True - The slider can have a selected range. False - Can't have a selected range.</td>
</tr>
<tr>
<td><strong>SelStart</strong></td>
<td>Used with <strong>SelLength</strong> to select a range of values in a Slider. Start of selected range. No effect if SelectRange is False.</td>
</tr>
<tr>
<td><strong>SelLength</strong></td>
<td>Used with <strong>SelLength</strong> to select a range of values in a Slider. Length of selected range. No effect if SelectRange is False.</td>
</tr>
</tbody>
</table>

### Appearance

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Orientation</strong></td>
<td>Horizontal (Default) or Vertical slider.</td>
</tr>
<tr>
<td><strong>TickStyle</strong></td>
<td>Tick marks display style. NoTicks; BottomRight - marks on bottom of horizontal sliders and to right of vertical sliders; TopLeft - marks on top of horizontal sliders and to left of vertical sliders; Both - both sides.</td>
</tr>
<tr>
<td><strong>TickFrequency</strong></td>
<td>Frequency of tick marks. If range is 100, and TickFrequency is 5, there will be 20 tick marks on slider.</td>
</tr>
<tr>
<td><strong>MousePointer</strong></td>
<td>The type of mouse pointer displayed when over the slider. Choose from 16 different types plus a custom pointer</td>
</tr>
<tr>
<td><strong>Text Position</strong></td>
<td>ToolTipText position, used for number readout when dragging. AboveLeft - above horizontal sliders and to left of vertical sliders. BelowRight - the other way.</td>
</tr>
<tr>
<td>MouseIcon</td>
<td>Custom icon to use when the MousePointer property is set to 99. Like Visual Basic, will not load animated cursor (.ani) files.</td>
</tr>
</tbody>
</table>
Control - Tree View

Insert a hierarchical tree display. Designed to display data such as organization trees, entries in an index, files and directories on disk, etc.

**Note:** Non-Common Control properties are prefaced with "tvw", suppressed in the following for greater legibility.

**Properties**

In addition to the properties listed below, a **Control tab** provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

**TreeView**

**General**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Style</strong></td>
<td>The graphics style (images, text, plus/minus boxes and lines) used to show each Node object. Text only; image and text; +/- and text; +/-, image and text; lines and text; lines, image, and text; (Default) lines, +/-, image and text.</td>
</tr>
<tr>
<td><strong>MousePointer</strong></td>
<td>The type of mouse pointer displayed when over the tree view. Choose from 16 different types plus a custom pointer</td>
</tr>
<tr>
<td><strong>LineStyle</strong></td>
<td>TreeLines - show lines between Node siblings and their parent Node. RootLines - also show lines between root nodes.</td>
</tr>
<tr>
<td><strong>LabelEdit</strong></td>
<td>Automatic - BeforeLabelEdit event is generated when the user clicks the label of a selected node. Manual - BeforeLabelEdit event generated only when the StartLabelEdit method is invoked.</td>
</tr>
<tr>
<td><strong>ImageList</strong></td>
<td>ImageList control to use with this treeview</td>
</tr>
<tr>
<td><strong>BorderStyle</strong></td>
<td>FixedSingle (default) or None. None may be used with Flat Appearance to achieve an uncaptioned rectangle of background color.</td>
</tr>
<tr>
<td><strong>Appearance</strong></td>
<td>3D or Flat. 3D is the standard Windows look. Flat results in a rectangular square of background color with a foreground color border.</td>
</tr>
<tr>
<td><strong>OLEDragMode</strong></td>
<td>DragManual (default) or DragAutomatic. DragManual means the program handles all OLE drag/drop operations, while DragAutomatic means the tree view handles all OLE drag/drop operations</td>
</tr>
<tr>
<td><strong>OLEDropMode</strong></td>
<td>Set to None (default) if the tree view does not accept OLE drops and is to display the No Drop cursor if an OLE drop is attempted. Set to Manual, the tree view will trigger OLE drop events, allowing programs to handle the OLE drop operation in code.</td>
</tr>
<tr>
<td><strong>Indentation</strong></td>
<td>Indentation of objects in the tree view.</td>
</tr>
<tr>
<td><strong>PathSeparator</strong></td>
<td>Delimiter character used for the path returned by the FullPath property. &quot;&quot; by default.</td>
</tr>
<tr>
<td><strong>HideSelection</strong></td>
<td>True or False. True means that highlighted text will not appear highlighted when the tree view loses the focus. False means that highlighted text stays highlighted even when another form or dialog has the focus.</td>
</tr>
<tr>
<td><strong>Sorted</strong></td>
<td>True - Node objects sorted by their Text property. False - Not sorted.</td>
</tr>
</tbody>
</table>
**FullRowSelect**
Specifies if the entire row is selected.

**Enabled**
True or False. True means the object can respond to user-generated events, false prevents it from responding.

**Checkboxes**
False (Default) - Checkboxes do not appear. True - Checkboxes appear.

**SingleSel**
Whether the item is expanded when selected. False (Default) - The item doesn't expand. True - the item expands.

**Scroll**
True - scrollbars are displayed. False (Default) - no scrollbars.

**HotTracking**
Whether or not mouse-sensitive highlighting is enabled. True - Header captions are highlighted as the mouse passes over them. False - HeaderItem objects do not respond to mouse movement unless the mouse button is clicked.

**Font**

**Properties**
Font properties that may be changes.

**Font**
Choose a font installed on this system. It's wise to choose standard Windows fonts such as MS Sans Serif that are universally available.

**Size**
Size of font, in points.

**Effects**
Bold, Italic, Underline or Strikeout.

**Sample Text**
A preview of the selected settings.

**Picture**

**MouseIcon**
Custom icon to use when the **MousePointer** property is set to 99. Like Visual Basic, will not load animated cursor (.ani) files.
Control - UpDown

Insert an increment/decrement control, also called spin buttons.

UpDown controls are most often used with another control, such as a Text Box, which is known as the buddy control of the UpDown. [For non-English speakers: a "buddy" is slang for a "friend."\]

In addition to the properties listed below, a Control tab provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

UpDown

General

Alignment
- AlignmentLeft - Place on left side of buddy control.
- AlignmentRight - Place on right side of buddy control.

Orientation
- OrientationVertical - Arrows point up/down.
- OrientationHorizontal - Arrows point left/right.

OLEDropMode
Set to None (default) if the UpDown does not accept OLE drops and is to display the No Drop cursor if an OLE drop is attempted. Set to Manual, the UpDown will trigger OLE drop events, allowing programs to handle the OLE drop operation in code.

Buddy

Buddy Control
Variant value that specifies the buddy control.

AutoBuddy
True - Automatically use previous control in tab order as buddy control.

SyncBuddy
True - UpDown synchronizes the Value property with the designated property (set in BuddyProperty) of the buddy control. False (Default) - no synchronization of Value with a property in the buddy control.

BuddyProperty
Property in buddy control to synchronize to the Value property of the UpDown. If no property is specified and SyncBuddy is True, then the default property of the buddy control is used.

Scrolling

Value
Long integer specifying current value, incremented or decremented by up and down arrows.

Min
Minimum value returned by the UpDown.

Max
Maximum value returned by the UpDown.

Wrap
True - wrap the value when user reaches the min or max value. False (Default) - don't wrap around.

Increment
The amount by which Value changes with each click of the up or down arrow. Default = 1.

Max is normally greater than Min. The up arrow always moves Value in the direction of Max and the down arrow always towards Min. Both can be negative numbers. If Max can be less than Min (very weird and asking for conceptual errors - not a good idea).

Note: Some texts on VB (including, surprisingly, MDSN) say that we cannot use the windowless, lightweight form of controls as a buddy control for the UpDown. That's not true, as wTextBox, for example works fine with the
UpDown both within Visual Basic and Manifold Visual Basic Scripting forms. Should Microsoft ever change this control in future releases so that windowless controls cannot be buddies, one could always simply use the UpClick and DownClick events generated by the UpDown to change the value in the text box.
Control - Tab Strip

Insert a tabbed control where clicking on each tab brings it to the fore. Also can be used to provide a toolbar look, including a cool "flat" toolbar look.

To load up a tab strip, one must create a container on the form that's loaded with the arrangement of controls to be displayed in the client area of the tab strip. At run time, as each tab is pressed we use Move to position the container full of desired controls into position into the client area.

**Note:** Non-Common Control properties are prefaced with "tab", suppressed in the following for greater legibility.

**Properties**

In addition to the properties listed below, a **Control tab** provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

**Tabla**

**General**

- **MultiRow** True - Show many tabs as cascaded rows. False - add left/right scroll buttons to scroll through more tabs than can fit in the width of the control.
- **ShowTips** True (Default) - Show ToolTipsText. False - Don't.
- **Enabled** True or False. True means the object can respond to user-generated events, false prevents it from responding.
- **MousePointer** The type of mouse pointer displayed when over the tab strip. Choose from 16 different types plus a custom pointer
- **Style** Tabs (Default) - standard tabbed look. Buttons - tabs display as a row of buttons with no border around client area. Use to create a toolbar look. FlatButtons - button is flat until pressed and then takes on an indented look.
- **TabWidthStyle** Used when MultiRow is True. Justified - evens out width of tabs to evenly fill each row. NonJustified - each tab takes on the width of its contents. Fixed - use TabFixedWidth for all tabs.
- **ImageList** ImageList control to use with this treeview
- **OLEDropMode** Set to None (default) if the tab strip does not accept OLE drops and is to display the No Drop cursor if an OLE drop is attempted. Set to Manual, the tab strip will trigger OLE drop events, allowing programs to handle the OLE drop operation in code.
- **Placement** Tabs appear at Top, Bottom, Left or Right side of the control. Use with TabStyle set to TabOpposite to achieve a (weird) effect as if tabs are being moved from one side of a book to another.
- **TabStyle** Used with MultiRow = True. TabStandard (Default) - remaining tabs stay on same side of the control. TabOpposite - Rows of tabs in front of the row containing the selected tab are displayed on the opposite side of the control.
- **TabFixedWidth** Specify a fixed width to use when TabWidthStyle is set to Fixed.
- **TabFixedHeight** Specify a fixed height to use. If not set, TabStrip will use either the height of the font or the height of the images to compute the height of tabs.
### Programming

**TabMinWidth**  
The minimum allowable width of a tab.

**HotTracking**  
Whether or not mouse-sensitive highlighting is enabled.  
True - captions are highlighted as the mouse passes over them.  
False (Default) - objects do not respond to mouse movement unless the mouse button is clicked.  
True is a good idea with FlatButton to achieve a "live" toolbar look that shows a raised button on a mouse hover.

**Separators**  
True - Draw separators between buttons when Style is set to Button or FlatButton.  
False (Default) - No separators.  
Separators help users understand this is a control and not just a caption when FlatButton is used.

**MultiSelect**  
Whether or not user can make multiple selections from the tab strip.  
NoMultiSelect means none.  
Simple, means a mouse click or SPACEBAR selects/deselects while arrow keys move focus.  
Extended adds CTRL and SHIFT click selection in the usual way.

### Tabs

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Index**    | Integer that uniquely identifies a tab object in the Tab Strip collection.  
Numbered in order of creation from the first tab object, which is always 1. |
| **Caption**  | Text for tab caption. |
| **Key**      | A unique string that identifies each tab object. |
| **Tag**      | Stores a string available for the programmer to use as desired.  
Often used to store an identification string of some sort. |
| **ToolTipText** | Tool tip text to display as tool tip for this tab. |
| **Image**    | Image to use for this tab, if ImageList specified. |

### Font

**Properties**  
Font properties that may be changes.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Font**     | Choose a font installed on this system.  
It's wise to choose standard Windows fonts such as **MS Sans Serif** that are universally available. |
| **Size**     | Size of font, in points. |
| **Effects**  | Bold, Italic, Underline or Strikeout. |
| **Sample Text** | A preview of the selected settings. |

### Picture

**MouseIcon**  
Custom icon to use when the **MousePointer** property is set to **99**.  
Like Visual Basic, will not load animated cursor (.ani) files.
Control - Picture Clip

Displays graphics from bitmap, icon, metafile, JPEG or GIF files.
Control - Multimedia Control

Manages Media Control Interface (MCI) devices like sound boards, MIDI sequencers, CD-ROM drives, audio players, videodisc players, etc. Add voice note recording to your dialog, or play spoken announcements.

This control provides push buttons that issue MCI commands to supported devices. The application should have the MCI device open before the user is allowed to push buttons. When recording audio, open a new file to be sure that the data file is in a format compatible with the system’s recording capability. Issue the MCI Save command before closing the device to store the recording in the file.

Note: Non-Common Control properties are prefaced with "mci", suppressed in the following for greater legibility.

Properties

In addition to the properties listed below, a Control tab provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

MMControl (Multimedia MCI Control)

General

- **DeviceType**: A string specifying type of MCI device to open: AVIVideo, CDAudio, DAT, DigitalVideo, MMMovie, Other, Overlay, Scanner, Sequencer, VCR, Videodisc or WaveAudio.
- **FileName**: file to be opened by Open or saved by Save. To change FileName at run time, must close and reopen the control.
- **MousePointer**: The type of mouse pointer displayed when over the Multimedia Control. Choose from 16 different types plus a custom pointer.
- **Orientation**: Horizontal (Default) or Vertical Multimedia Control.
- **BorderStyle**: FixedSingle (default) or None. None may be used with Flat Appearance to achieve an uncaptioned rectangle of background color.
- **RecordMode**: Either RecordInsert or RecordOverwrite. Must try and see with a device. WaveAudio devices support Insert mode only.
- **OLEDropMode**: Set to None (default) if the Multimedia Control does not accept OLE drops and is to display the No Drop cursor if an OLE drop is attempted. Set to Manual, the Multimedia Control will trigger OLE drop events, allowing programs to handle the OLE drop operation in code.
- **UpdateInterval**: The number of milliseconds between successive StatusUpdate events.
- **Frames**: The number of frames Step or Back commands will move forward or backward.
- **Silent**: True - Sound is turned off. False - any sound is played.
- **Shareable**: True - more than one control or application can open this device. False - only one at a time.
- **AutoEnable**: True (Default) - enable/disable buttons whose functions make sense or not given the device’s capabilities. False - buttons set by properties specified. True only works if the button is otherwise enabled in controls properties.
- **Enabled**: True or False. True means the object can respond to user-generated events, false prevents it from responding.
### Controls

Programming

Control - Status Bar

Provides a status bar like those at the bottom of many program windows. May be divided up into up to sixteen Panel objects, contained in a Panels collection. Panel objects can contain text and/or a picture and can automatically display frequently desired information such as time, date, etc.

**Note:** Non-Common Control properties are prefaced with "sbr", suppressed in the following for greater legibility.

**Properties**

In addition to the properties listed below, a **Control tab** provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

**StatusBar**

**General**

- **Style**
  - Normal - Show all Panel objects. Simple - display one large panel.

- **MousePointer**
  - The type of mouse pointer displayed when over the status bar. Choose from 16 different types plus a custom pointer

- **SimpleText**
  - Text to show when Style is set to Simple.

- **OLEDropMode**
  - Set to None (default) if the status bar does not accept OLE drops and is to display the No Drop cursor if an OLE drop is attempted. Set to Manual, the status bar will trigger OLE drop events, allowing programs to handle the OLE drop operation in code.

- **Enabled**
  - True or False. True means the control can respond to user-generated events, false prevents it from responding.

- **ShowTips**
  - True (Default) - Show ToolTipsText. False - Don't.

**Panels**

- **Index**
  - Integer that uniquely identifies a panel object in the Status bar collection. Numbered in order of creation from the first panel object, which is always 1.

- **Text**
  - Text for panel caption.

- **ToolTipText**
  - Tool tip text to display as tool tip for this panel.

- **Key**
  - A unique string that identifies each panel object.

- **Tag**
  - Stores a string available for the programmer to use as desired. Often used to store an identification string of some sort.

- **Alignment**
  - Controls alignment of text or pictures in the panel. Left, Center or Right.

- **Style**
  - Choose from Text, to display panel's Text property, or from a collection of standard capabilities showing keyboard status.
    - **Text** - Text and/or a bitmap.
    - **Caps** - Caps lock key on/off.
    - **Num** - Num lock key on/off.
    - **Ins** - Insert key enabled on/off.
    - **Scrl** - Scroll lock key on/off.
Time - Show time in system format.
Date - Show date in system format.
Kana - Kana lock on/off [Japanese o/s only].
Bevel NoBevel - Flat text. Inset (Default) - Panel is sunk into status bar. Raised - Panel is raised up.
AutoSize What to do when container (form) resized. NoAutoSize - Width of panel specified by Width property. Spring - All panels resize to new space. [use on middle panels] Contents - Panel resizes to fit contents.
MinimumWidth Panel cannot shrink to less than this width.
ActualWidth Reports actual width of panel
Picture Bitmap to use for this panel.
Enabled True or False. True means the panel can respond to user-generated events, false prevents it from responding.
Visible True - Panel is visible. False - It isn't.

Font
Properties Font properties that may be changes.
Font Choose a font installed on this system. It's wise to choose standard Windows fonts such as MS Sans Serif that are universally available.
Size Size of font, in points.
Effects Bold, Italic, Underline or Strikeout.
Sample Text A preview of the selected settings.

Picture
MouseIcon Custom icon to use when the MousePointer property is set to 99. Like Visual Basic, will not load animated cursor (.ani) files.
Control - Tool Bar

Creates a customizable toolbar at the top of the form that hosts buttons or other controls. Toolbars contain a collection of Button objects. Button objects created using Placeholder style can reserve space on the toolbar for other controls, like ComboBox controls.

Buttons can have text, images or both. Images are fetched from an ImageList control collection. Buttons are programmed by adding code to the ButtonClick event for each button.

Buttons may even have menus within them when the button uses Dropdown style. Each button in the Buttons collection can itself have a collection of ButtonMenu objects.

Note: Non-Common Control properties are prefaced with "tbr", suppressed in the following for greater legibility.

Properties

In addition to the properties listed below, a Control tab provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

ToolBar

General

MousePointer  The type of mouse pointer displayed when over the Toolbar. Choose from 16 different types plus a custom pointer

OLEDropMode  Set to None (default) if the Toolbar does not accept OLE drops and is to display the No Drop cursor if an OLE drop is attempted. Set to Manual, the Toolbar will trigger OLE drop events, allowing programs to handle the OLE drop operation in code.

ImageList  ImageList to use for buttons in normal mode.

DisabledImageList  ImageList to use for disabled buttons.

HotImageList  ImageList for "hot" images: appear on button on mouse hover when Style is Transparent.

HelpContextID  Context ID for this control to use for this toolbar.

ButtonHeight  Height of button. Updated to accommodate string in Caption property or image in Image property for the button.

ButtonWidth  Width of button. Updated to accommodate string in Caption property or image in Image property for the button.

Appearance  3D or Flat. 3D is the standard Windows look. Flat has no effect with command buttons.

Text Alignment  Position of text relative to button. TextAlignbottom or TextAlignRight

Style  Standard or Flat, the appearance of the toolbar control as either a "3D" look or as a flat look.

HelpFile  A filename for path and filename of the help file to use with this toolbar.

AllowCustomize  True - allow user to customize toolbar by double clicking on it. False - no user customization allowed.

ShowTips  True (Default) - Show ToolTipsText. False - Don't.
Wrappable  True - buttons wrap if form resized. False - No wrapping.

Enabled  True or False. True means the object can respond to user-generated events, false prevents it from responding.

BorderStyle  FixedSingle (default) or None.

Buttons

Index  Integer that uniquely identifies a button object in the Toolbar collection. Numbered in order of creation from the first button object, which is always 1.

Caption  Text for button caption.

Key  A unique string that identifies each button object.

Style  Specify button behavior:

  Default  Standard toolbar button click and it bounces back.

  Check  Used for toggles/mode buttons. Pushed in and stays in until pushed out.

ButtonGroup  Allows only one button in the group to be pushed in.

Separator  No function. A spacer of eight pixels.

Placeholder  Reserves space into which other controls can be placed.

Dropdown  Enables use of button menu on this button. Creates a small down arrow to indicate the presence of a dropdown menu.

ToolTipText  Tool tip text to display as tool tip for this button.

Tag  Stores a string available for the programmer to use as desired. Often used to store an identification string of some sort.

Visible  True - Button is visible. False - It isn't.

Enabled  True or False. True means the button can respond to user-generated events, false prevents it from responding.

MixedState  Dithers the images on the button to be used to display indeterminate states associated with that button.

Description  Description that will appear for this button when the Customize Toolbar dialog is invoked.

Value  Pressed or Unpressed.

Width (Placeholder)  Width to use for placeholder Style buttons.

Image  Image number from ImageList.

ButtonMenus

Index  Integer that uniquely identifies a ButtonMenu object in the button menu collection. Numbered in order of creation from the first ButtonMenu object, which is always 1.

Text  Text for menu item.

Key  A unique string that identifies each ButtonMenu object.
**Tag**  Stores a string available for the programmer to use as desired. Often used to store an identification string of some sort.

**Enabled**  True or False. True means the button can respond to user-generated events, false prevents it from responding.

**Visible**  True - Button is visible. False - It isn't.

**Picture**

**MouseIcon**  Custom icon to use when the MousePointer property is set to 99. Like Visual Basic, will not load animated cursor (.ani) files.
Control - Cool Bar

Provides a modern, "railbar" look and the ability to create user configurable toolbars like those in IE. Requires installation of Internet Explorer 3.0 or greater on both the development machine and the run-time machine.

The CoolBar is a container that can host child controls; however, a CoolBar can only host controls that expose a window handle (so, no windowless lightweight controls as are found on the frequently used Tools toolbar in Manifold). The resizable regions in a CoolBar are called bands. Each band can host a child control.

Properties

In addition to the properties listed below, a Control tab provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

CoolBar

General

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ImageList</td>
<td>ImageList to use for the CoolBar.</td>
</tr>
<tr>
<td>Orientation</td>
<td>Vertical or Horizontal</td>
</tr>
<tr>
<td>Picture</td>
<td>Image to use to &quot;tile&quot; CoolBar. Calls Picture and Color (see below) properties dialog.</td>
</tr>
<tr>
<td>EmbossPicture</td>
<td>Convert picture to monochrome 3D look.</td>
</tr>
<tr>
<td>EmbossHighlight</td>
<td>Color to use for embossing highlights. Available when EmbossPicture is used.</td>
</tr>
<tr>
<td>EmbossShadow</td>
<td>Color to use for embossing shadows. Available when EmbossPicture is used.</td>
</tr>
<tr>
<td>ForeColor</td>
<td>Foreground color (text).</td>
</tr>
<tr>
<td>BackColor</td>
<td>Background color of coolbar.</td>
</tr>
<tr>
<td>BandBorders</td>
<td>True - Apply 3D borders between band rows.</td>
</tr>
<tr>
<td>FixedOrder</td>
<td>True - User cannot rearrange bands at run time. False - User can rearrange bands.</td>
</tr>
<tr>
<td>VariantHeight</td>
<td>True (Default) - Band heights may vary. False - Band heights are all the same.</td>
</tr>
</tbody>
</table>

Bands

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Index</td>
<td>Integer that uniquely identifies a band object in the CoolBar collection. Numbered in order of creation from the first band object, which is always 1.</td>
</tr>
<tr>
<td>Child</td>
<td>Loaded with controls drawn on this CoolBar. Choose a control from the Child list and press Apply to associate it with this band.</td>
</tr>
<tr>
<td>Style</td>
<td>BandNormal (Default) Band can be resized. BandFixedSize Band can not be resized.</td>
</tr>
<tr>
<td>UseCoolBarPicture</td>
<td>Tile this band with the coolbar picture.</td>
</tr>
<tr>
<td>EmbossPicture</td>
<td>Show picture in two colors. Available if UseCoolBarPicture is not checked.</td>
</tr>
<tr>
<td>EmbossHighlight</td>
<td>Color to use for embossing highlights. Available when EmbossPicture is used.</td>
</tr>
</tbody>
</table>
EmbossShadow  Color to use for embossing shadows.  Available when EmbossPicture is used.

UseCoolbarColors  Use the same colors as defined for CoolBar

ForeColor  Foreground color.  Available when UseCoolbarColors is not checked.

BackColor  Background color.  Available when UseCoolbarColors is not checked.

Caption  Text for band caption.

Width  Width of this band.

MinWidth  Minimum width allowed during resizing.

MinHeight  Minimum height allowed during resizing.

Key  A unique string that identifies each band object.

Tag  Stores a string available for the programmer to use as desired.  Often used to store an identification string of some sort.

Image  Image from ImageList to use for this band.  Image will be displayed at run time between the move handle and the caption.

Visible  True - Band is visible.  False - It isn't.

AllowVertical  True (Default) - This band will be displayed if CoolBar in vertical orientation.  False - Will not be displayed when vertical.

NewRow  Place on new row.

FixedBackground  True (Default) - background picture is fixed on resize.  False - retile background picture on resize.

Color

Back Color  Color to be used for the band's background.

EmbossHighlight  Color to use for "light" color.

EmbossShadow  Color to use for "dark" color.

ForeColor  Color to be used for the band's foreground, the color of the text caption.

Color Set  Choose from Standard Colors (standard Windows non-dithered colors) or Windows System Colors. The latter will be defined by the user's Control Panel settings and is normally the setting used so that the form changes appearance like the rest of Windows if the Control Panel settings are changed.

Color Palette  Displays available colors.  Click on the property to be changed to highlight it in the Properties pane, click on the desired color in the Color Palette pane and then press Apply.

Edit Custom Color  Change the custom color presented in the Color Palette when the Color Set is set to Windows System Colors.
Control - Common Dialog Control

Provides a standard set of Windows dialog boxes for opening and saving files and selecting colors and fonts, and printing. Can also display Help. Invisible at run time until called.

Properties

In addition to the properties listed below, a Control tab provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

CommonDialog

Open / Save As

Displayed by ShowOpen and ShowSave methods.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DialogTitle</td>
<td>Name to display in the title bar.</td>
</tr>
<tr>
<td>FileName</td>
<td>Initial path and file name to use, if desired.</td>
</tr>
<tr>
<td>InitDir</td>
<td>Initial directory to use. If not present, current directory will be used.</td>
</tr>
<tr>
<td>Filter</td>
<td>String specifying the file extension. * .txt specifies all text files. Can specify more than one type.</td>
</tr>
<tr>
<td>CancelError</td>
<td>False (Default) - no error generated when user chooses the Cancel button. True - error is generated.</td>
</tr>
<tr>
<td>Flags</td>
<td>A numeric value that is a combination of numeric values for various flags (listed in purple color below) that are summed to create the Flags value. See Microsoft's MSDN documentation for numeric values for the following flags.</td>
</tr>
<tr>
<td>AllowMultiselect</td>
<td>User can select more than one file.</td>
</tr>
<tr>
<td>CreatePrompt</td>
<td>Prompts user to create file that does not exist.</td>
</tr>
<tr>
<td>Explorer</td>
<td>For '95 and 4.0: use Explorer-like Open A File dialog box template.</td>
</tr>
<tr>
<td>ExtensionDifferent</td>
<td>Indicates extension of returned filename is different from extension specified by DefaultExt.</td>
</tr>
<tr>
<td>FileMustExist</td>
<td>User must enter name of existing file.</td>
</tr>
<tr>
<td>HelpButton</td>
<td>Display help button.</td>
</tr>
<tr>
<td>HideReadOnly</td>
<td>Hides the Read Only check box.</td>
</tr>
<tr>
<td>LongNames</td>
<td>Use long file names.</td>
</tr>
<tr>
<td>NoChangeDir</td>
<td>Dialog will set current directory to what it was when dialog was opened.</td>
</tr>
<tr>
<td>NoDereferenceLinks</td>
<td>Do not dereference shortcuts (shell links).</td>
</tr>
<tr>
<td>NoLongNames</td>
<td>No long file names allowed.</td>
</tr>
<tr>
<td>NoReadOnlyReturn</td>
<td>Returned file won't have Read Only set and won't be in a write-protected directory.</td>
</tr>
<tr>
<td>NoValidate</td>
<td>Allows invalid characters in the returned filename.</td>
</tr>
<tr>
<td>OverwritePrompt</td>
<td>User must confirm to overwrite an existing file.</td>
</tr>
</tbody>
</table>
PathMustExist User can only enter valid paths.
ReadOnly Read only box checked by default.
ShareAware Sharing violation errors will be ignored.

DefaultExt Default filename extension, such as .txt or .mdb.
MaxFileSize Integer specifying the maximum size of the filename in bytes. Default is 256.
FilterIndex Specifies the default filter when using Filter property. First defined filter is 1.

Color Displayed by ShowColor method.

Color Returns or sets selected color.
Flags A numeric value that is a combination of numeric values for various flags (listed in purple color below) that are summed to create the Flags value. See Microsoft's MSDN documentation for numeric values for the following flags.
FullOpen Entire color dialog is shown.
HelpButton Display a help button.
PreventFullOpen Prevent definition of Custom Colors.
RGBInit Initial color value for dialog box.
CancelError False (Default) - no error generated when user chooses the Cancel button. True - error is generated.

Font Displayed by ShowFont method.

FontName Selected font name.
FontSize Selected font size.
Min, Max Smallest and largest font sizes.
Flags A numeric value that is a combination of numeric values for various flags (listed in purple color below) that are summed to create the Flags value. See Microsoft's MSDN documentation for numeric values for the following flags.
ANSIOnly Only those fonts that use Windows character set.
Apply Enable the Apply button.
Both List screen and printer fonts.
Effects Enable strikethrough, underline and color effects.
FixedPitchOnly Selects only fixed-pitch fonts.
ForceFontExist Allow use only of fonts that exist.
<table>

</table>

**Print**

- **Print**
  - Displayed by the `ShowPrinter` method.

**Copies**

- Default number of copies to print.

**Flags**

- A numeric value that is a combination of numeric values for various flags (listed in purple color below) that are summed to create the `Flags` value. See Microsoft’s MSDN documentation for numeric values for the following flags.

**AllPages**

- State of All Pages option button.

**Collate**

- State of Collage check box.

**DisablePrintToFile**

- Disable Print to File check box.

**HelpButton**

- Show help button.

**HidePrintToFile**

- Hide Print to File check box.

**NoPageNums**

- Disable Pages option button and edit control.

**NoSelection**

- Disable Selection option button.

**NoWarning**

- Don’t warn if no default printer.

**PageNums**

- State of Pages option button.

**PrintSetup**

- Show Print Setup dialog instead of Print dialog box.

**PrintToFile**

- State of Print to File check box.

**ReturnDC**

- Return device context for printer selection made.
**ReturnDefault**  Return default printer name.

**ReturnIC**  Return information context for printer selection made.

**Selection**  State of selection option button.

**UseDevModeCopies**  If printer driver doesn’t support multiple copies, will disable the Number of copies spinner in Print dialog.

**FromPage, ToPage**  Default from and to page numbers.

**Min, Max**  Smallest number allowed in From box and the largest number allowed in the To box.

**Orientation**  Portrait or Landscape

**PrinterDefault**  True - Any changes user makes via Setup button will change printer defaults in the system registry. False - Setup selections in this dialog will not change system settings.

**CancelError**  False (Default) - no error generated when user chooses the Cancel button. True - error is generated.

## Help

**HelpContext**  HelpContextID: 0 - no context number >= 0 - a valid help context number.

**HelpKey**  String identifying keyword that identifies the Help topic.

**HelpFile**  Path and filename for Help file to use.

**HelpCommand**  A numeric value that is a numeric value representing one of the following options (in purple color). See Microsoft’s MSDN documentation for numeric values for the following options.

- **Command**  Execute a Help macro.
- **Contents**  Display Help contents topic.
- **Context**  Display Help for a particular context.
- **ContextPopup**  Display in pop-up a Help topic identified by a context number.
- **ForceFile**  Ensures WinHelp displays correct Help file.
- **HelpOnHelp**  Show Help for total idiots, who need help on using Help.
- **HelpIndex**  Display index of the given Help file.
- **HelpKey**  Display Help for a particular keyword.
- **PartialKey**  Search on partial keys and show matches, if any.
- **HelpQuit**  Tell Help the given help file is no longer in use.
- **SetContents**  Specify which Contents topic is shown when user presses the F1 key.
- **SetIndex**  Used when more than one index per Help file (don't do this).
Control - System Info Control

Detects system events such as desktop resizing, resolution changes, time changes. Also provides operating system platform and version information and changes in AC/battery power status and Plug/Play hardware configuration. Used when writing applications for portable devices (GIS in the field) and for developing info for your tech support team.

There are no properties settable at design time for the SysInfo control. It is invisible at run time

Frequently Used Run Time Properties and Events

In addition to the properties listed below, a Control tab provides access to certain frequently used form properties for this control. See the Form Properties topic for information on those properties.

SysInfo

Operating System

OSPPlatform Operating system.
OSVersion Version of the operating system.
OSBuild Build number of the operating system.

Desktop

ScrollBarSize Width of scroll bar in twips.
WorkAreaHeight, WorkAreaLeft, WorkAreaTop, WorkAreaWidth Height, left edge, top edge, and width of visible desktop adjusted for the Windows taskbar.
DisplayChanged Occurs when screen resolution changes.
SysColorsChanged Occurs when system color setting changes.

Note: Plug and Play hardware events are not listed in this table.

Power

ACStatus System using AC or battery power.
BatteryFullTime Value indicating full charge life of battery.
BatteryLifePercent Percentage of battery power remaining.
BatteryLifeTime Value indicating remaining life of battery.
BatteryStatus Status of battery's charge.
PowerQuery Suspend Occurs when system power about to be suspended.
PowerResume Occurs when system comes out of suspend mode.
PowerStatus Changed Occurs when power status of system changes.
PowerSuspend Occurs immediately before the system goes into suspend mode.
Control - Insert ActiveX Control

Insert any ActiveX control available on this system. Opens a dialog that lists ActiveX controls available on this system.

Choose a module from the list and press OK. The Register Module button is for use in cases where ActiveX controls exist on our system but have not yet been registered (for example, if we simply copy over an .ocx file into our ~/System32 directory but have not run an installation script or have otherwise manually registered it). It does not hurt to Register Module if a module has already been registered.

Next, click and drag into the form where the ActiveX control is to appear. Right-click on the control to set its properties, if any are settable at design time.

Debugger

The Manifold Debugger provides an integrated debugger for use with scripting in Manifold System running in 32-bit mode. The debugger is not available when Manifold is running in 64-bit mode in 64-bit Windows systems, nor at the present writing is it available in Vista. The Manifold debugger requires installation of Microsoft facilities that support debugging of ActiveX scripts (see below), which are not available in 64-bit mode in Windows. See the 32-bit and 64-bit Manifold Editions topic when running 64-bit Manifold System editions.

The Manifold debugger does not work with .NET languages (which, in addition to ActiveX languages also may be used for scripting within Manifold). .NET languages have their own debugging framework. Attempting to enter a .NET script under the debugger will display an error message.

The debugger works with VBScript, JScript and any other ActiveX scripting engine that supports Microsoft debugging calls. Note that at the present writing the ActiveState PERL and Python scripting languages do not support Microsoft debugging calls and so may not be used with the debugger even though they may be used for scripting.

Likewise, scripts written in .NET languages such as C#, VB .NET or JScript .NET are not supported by the debugger and should be debugged using the Microsoft console debugger that is part of the free .NET SDK download. Debugger commands, including the project pane's Run under Debugger button, will automatically be disabled if a script window uses .NET languages.

The debugger works together with the Call Stack, Variables and Watches panes and is controlled by the Tools toolbar configured with debugger commands when a script is open. The Edit - Breakpoints command is used to set breakpoints for use with the debugger.

Scripts associated with Active Columns can also run in the debugger. To debug an Active Column script, right click on an Active Column cell and choose Run under Debugger from the pop up menu. Doing this runs the
function, which will generate values for the active column in the context of the clicked cell. All regular runs of Active Column functions are done without the debugger.

If the Debugger is installed, when a script has the focus the tools toolbar will have debugger commands enabled. The debugger helps us develop and debug scripts in the scripting language of our choice. Commands will be enabled in the debugger toolbar as make sense given the execution state of the script.

- **Run** Run a script.
- **Run under Debugger** Run a script under control of the debugger.
- **Pause** Pause execution of a script.
- **Stop** Stop execution of a script.
- **Step Over** Step over a function.
- **Step Into** Step into a function.
- **Step Out** Step out of a function.

**What is a Debugger?**

A debugger is a specialized execution environment within which programs (like Manifold scripts) may be run in a controlled way that helps debug those programs. When a script is running under the control of a debugger it may be started and stopped, paused, re-started at a different location in the code, automatically stopped whenever it reaches a marked breakpoint and so on. At any time when a program is paused or stopped we can see what are the values of any variables or other information we would like to know.

To understand what a debugger does, let's take a moment to consider the old-fashioned way of writing and debugging programs. Traditionally, we can write a program that consists of one or more functions. If it works the first time without any flaws we're somewhat surprised but happy. More frequently a new program of any complexity will not work quite right the first time or it will exhibit unexpected behavior (a "bug") when it functions. To track down any problems we have to know what is going on inside the program as it executes.

The traditional way of finding out what a program is doing while it is executing is to insert additional lines of code for debugging purposes. For example, if we are not sure that the program reaches a particular function correctly we might insert a few lines of code that when that function is reached will print out some text like "Got to AddNextRecord() OK" or which might print out the values of variables that we suspect are being mishandled with printed output like "Executing LoopRecord with RecordNum = 36".

As any professional programmer knows, it's really tedious to lard up one's code with lots of extra debugging statements. Adding extra statements is slow and there is always the risk of forgetting some debugging statements within production code or of inadvertently changing the execution of a program by the debugging code.

A much faster way to debug code is to use a debugger like the Manifold debugger. The Manifold debugger takes advantage of features built into Microsoft's Active X scripting environment to provide sophisticated, professional-class debugging capability.

To stop the execution of a program at any given location, insert a **breakpoint** at that spot using the Edit - Breakpoints command. Whenever program flow reaches a breakpoint the program will pause at that point. We can then see the contents of any variables using the Variables pane. If we like, we can even change the content of any variable by changing it's value in the the Variables pane.

The tools toolbar allows us to control program flow within the script. Using the Call Stack pane we can even jump to different parts of the script. The Watches pane allows us to see variables, process parameters and even computed expressions. All together the ensemble of debugger tools toolbar commands and the Call Stack, Variables and Watches panes allow us to control and examine the execution of a script with much greater convenience and flexibility than is possible using traditional methods.
**Debugger Tutorial**

The following sequence of steps shows operation of the debugger together with Call Stack, Variables and Watches panes.

1. Launch Manifold, open a new project and create two scripts. The first script, called **A**, is as follows:

```
Sub Main
    Set components = Application.ActiveDocument.ComponentSet
    Set anotherScript = components(components.ItemByNames(“B”))
    anotherScript.Run
End Sub
```

The second script, called **B**, is:

```
Sub SayHello
    str = “Hello!”
    Application.MessageBox str
End Sub

Sub Main
    Call SayHello
End Sub
```

2. Using **Edit - Breakpoints** place breakpoints in the scripts as shown above.

3. Try running script **A** or **B** from the project pane. Verify that both scripts display a “Hello!” message.

4. Turn on the Call Stack, Variables and Watches panes and dock them so that all three panes are visible.

5. Open script **A** and run it under the debugger using the toolbar button in the Tools toolbar or the **Script - Run under debugger** menu command.

6. The script will stop at the breakpoint in the fourth line of script **A**. The Call Stack pane shows that we’re within “Main” at line 4. The Variables pane shows “components” and “anotherScript” variables. The Watches pane is empty.

7. In the Variables pane, expand the **components** entry. The **Count** item shows that component set consists of two components (script **A** and script **B**). The other two items variables are internal to Manifold and may be replaced in future editions with a more sensible list of components. Expand the **anotherScript** item. The **Name** item shows the name of the script component. Other items show the script language, script text and various other properties. Press in the **Show Common Properties** button in the the pane toolbar. This shows the **Application** and **Parent** properties that are common to all Manifold objects. Note that we can expand **components** and then expand its **Application** property, then expand the Application’s **ActiveDocument** property and so on. Press out the **Show Type** button within the pane toolbar. This will hide the **Type** column so there will be more room for the **Name** and **Value** columns.

8. In the Watches pane, click the **New Watch** button and enter “components”. This will display the contents of the **components** variable in a manner similar to the Variables pane. Click the **New Watch** button once more and enter “components.Count + 1”. This will display “3”. Double-click the empty line below the list of watches (an
alternative way to create a new watch) and enter "Application". This will display the built-in Application object. Click on the first watch to highlight it and click the Delete Watch button within the toolbar. This will delete the selected watch. Note that the Delete Watch button won’t work on a subitem. For example, it won’t work on the Application.ActiveDocument item within the Application watch. The Show Common Properties and Show Type buttons operate do the analogous buttons in the Variables pane toolbar.

9. Click the Step Into button within the Tools toolbar or choose the equivalent command in the Script menu. This will step into script B.

```
Sub SayHello
    str = "Hello!"
    Application.MessageBox str
End Sub

Sub Main
    Call SayHello
End Sub
```

The yellow execution arrow shows where execution has stopped. Click the Run Under Debugger button to continue execution. The script will stop on a breakpoint within the SayHello sub in script B.

```
Sub SayHello
    str = "Hello!"
    Application.MessageBox str
End Sub

Sub Main
    Call SayHello
End Sub
```

10. Let’s take a look at the Call Stack pane. The first line reads “SayHello” while both the second and third line read “Main”. Press in the Show Module button to show the module (script) name for each call. Press in the Show Line Position button to show the position of a call within a line (useful when you have more than one call on the same line). Click the Show Language button to show the language of each script module. Click on the last call, for module A function Main line 4, to highlight it and click the Go To button in the Call Stack pane toolbar. This will activate script A and mark the location of this call in the script window with a green arrow:

```
Sub Main
    Set components = Application.ActiveDocument.ComponentSet
    Set anotherScript = components(components.ItemByName("B"))
    anotherScript.Run
End Sub
```

It will also mark the respective item in the Call Stack pane with a green arrow as well:
The Variables pane will display "components" and "anotherScript" declared within the scope of this call. The "components.Count+1" entry in the Watches pane will read "3". Double-click the second line within the Call Stack pane, reading module B, function Main, line 7. Double-clicking a line in the Call Stack pane is an alternative way to Go To a call. This will activate script B.

Note that line 7 that contains the current call is marked with a green arrow and line 3 containing the current execution line is still displayed with a yellow arrow overlaid on the breakpoint dot. The Variables pane will display no entries since the Main routine in script B declares no local variables. The components.Count + 1 entry within the Watches pane will read "Variable is undefined: components" since "components" is inaccessible within the scope of the Main routine in script B.

Double-click the first line within the Call Stack pane, for module B, function SayHello and line 3. The Variables pane will display the name str and value "Hello!" as well as the type String if the Type column is on. The Watches pane will still refuse to evaluate the value of the components.Count+1 expression, since it inaccessible with the scope of the SayHello routine.

11. In the Watches pane add a watch for the str variable. This will display "Hello!". Now, double-click the value box of the "str" variable (that is, click on the cell with "Hello!" in it) either within the Variables pane or within the Watches pane. Change "Hello!" to just "Hi!" and press Enter. Both Variables and Watches will now display the value of str as "Hi!". Click the Run Under Debugger button in the Tools toolbar to continue execution. Note that greeting in the message box has also changed to "Hi!". Click OK to dismiss the message and finish the script.

12. Note that all watches will turn to "Unavailable". We can still add or remove watches but we can not (obviously) edit their content. The Call Stack and Variables panes will disable their lists.

**Installation Requirements**

The Manifold Debugger is designed to work with Microsoft ActiveX scripting languages as used within Manifold System and to take advantage of the debugging capabilities Microsoft has built into the ActiveX ensemble of technologies.

To run the Debugger, you must therefore have the Microsoft Process Debug Manager (PDM) DLL installed on your system. This DLL gets installed with various Microsoft products aimed at scripting development. If you don't have the PDM or don't know if you have it, you must install the PDM on your machine. Unfortunately, due to what appears to be an inadvertent error in Microsoft licensing, although the PDM is freely usable and obtainable from Microsoft it is not included in the "redistributables" list covering all other Microsoft ActiveX components issued to developers like manifold.net for redistribution to end users. manifold.net therefore cannot provide the PDM as part of the Debugger installation on CD.
The easiest way to assure you have the PDM correctly installed on your system is to download any of the free Microsoft items that install it. The recommended choice is to install the Microsoft Script Debugger for the Windows system you are using from the following URL (making sure to enter the entire URL as a single line in your browser):

The above URL was correct at the time of this writing. If it is no longer active, visit the Microsoft web site for a current URL, or search for "Microsoft Script Debugger" using Google or some other search engine to find Microsoft's new download page. Note that the debugger comes in different versions for different Microsoft operating systems, so make sure you get the version that is correct for your system. For example, if running Windows XP make sure you get the version for Windows XP and not the one for Windows 98 or other Windows edition.

Note that at the present writing the Microsoft Script Debugger is not available for either 64-bit Windows systems or Vista.

You must have Administrator privileges in Windows 2003, XP and 2000 when installing the script debugger.

Note: The Microsoft Script Debugger is a small, simple, command-line debugger that also uses the PDM. It is more primitive than the Manifold Debugger, but it does install the PDM DLL required by the Manifold Debugger. Users new to working with debuggers may also find the documentation links available from the URL above to be a helpful introduction to debugging concepts used in the Microsoft scripting world by the Manifold Debugger and all other standard ActiveX scripting tools.

Extensions

Extensions

Manifold can be extended in the following ways:

- By writing add-ins. Add-ins are short scripts that users can run in the context of the currently opened document. Add-ins can be written using any of the scripting languages supported by Manifold, including C#, VB .NET, VBScript, JScript and others, and can utilize external libraries and objects, via .NET, COM and other technologies.

- By writing geocoding server modules. Geocoding server modules are .NET modules with objects supporting the Manifold Geocoding Server Interface. Geocoding server modules are used to connect to external geocoding services for geocoding address data.

- By writing image server modules. Image server modules are .NET modules with objects supporting the Manifold Image Server Interface. Image server modules are used to connect to image data sources and expose their data as image components.

While add-ins are only available for use within interactive Manifold sessions, and can not be used as they are from external applications utilizing the Manifold object model or from IMS web sites, geocoding server modules and image server modules are available for use both in interactive Manifold sessions as well as programmatically from external applications and web sites.

Add-Ins
Geocoding Server Interface
Image Server Interface
Geocoding Server Interface

The Manifold Geocoding Server interface is a .NET interface used with geocoding server modules. Geocoding server modules connect to external geocoding services and geocode address data. For example, geocoding server modules can act as intermediaries between Manifold and various web sites that expose programmatic interfaces for doing simple geocoding tasks.

A Manifold Geocoding Server module should include one or more .NET objects exposing the Manifold Geocoding Server interface. Each of the objects should have a public parameterless constructor.

Installing a Manifold geocoding server module consists of installing the .NET assembly that contains .NET objects exposing the Manifold Geocoding Server interface into the Manifold installation folder, and doing the necessary configuration required by the assembly. There is no configuration required on the Manifold side besides copying the assembly into the Manifold installation folder and restarting Manifold.

Connecting to a Manifold geocoding server consists of creating an instance of the particular .NET object, and calling its methods to geocode data.

Interface Specification

The Manifold Geocoding Server interface includes the following members:

IServer

IResults Geocode(String address)

Geocode the specified address and return a set of matches.

String Country

Get default country. Return a blank string if the server supports more than one country.

String Name

Get the unique name of the geocoding server module. Only alphanumeric characters, spaces, and ., -, :, _, <, >, '{', '}', '[' and ']' characters are permitted.

Boolean Remote

Return True if Manifold should minimize the number of geocoding requests, and False otherwise. Commonly used with servers accessed via the web or via slow network connections.

(Supplementary interfaces)

IResult

String Address

Get street address.

String City

Get city name.

String Country

Get country name.

Double Latitude

Get latitude value from -90 to 90. If latitude value is unknown, return InvalidCoord.

Double Longitude

Get longitude value from -180 to 180. If longitude value is unknown, return InvalidCoord.
Programming

String State
Get state name or province name.

String Zip
Get zip code or postal code.

IResults

Int32 Count
Get number of available results.

IResult this[Int32 index]
Get result with given index, from 0 to Count-1. This is an indexer property.

The definition of the main Geocoding Server interface and supplementary interfaces resides in Manifold.GeocodingServer.dll.

All interfaces are defined in the Manifold.GeocodingServer namespace.

Notes

Implement all members of the Manifold Geocoding Server interface, or the geocoding server module will not be functional. Pay close attention to the meaning of each property and method.

Make sure to name your geocoding server module in a unique way. A common technique is to use the name of your company or project as part of the name for a geocoding server module, for example, Acme Corp Geocoding Server for Canada. Do not use any characters that are not explicitly permitted.

Limit the amount of memory used by your geocoding server module to a minimum. If you want to cache the results returned by the server, be sure to design and follow a robust caching policy. Do not blindly cache every result without ever pruning the cache.

Limit the amount of bandwidth used by your geocoding server module. Return True in the Remote property if you are going to use a web connection or a slow network connection.

Design your geocoding server module to operate with minimal permissions. At the very least, your module should operate in the context of a normal user account. It is frequently beneficial to declare all permissions required by the module via .NET mechanisms, for use in limited-permission environments.

Design your geocoding server module so it does not require any configuration. If you want the user to be able to customize the operation of the module, provide an interactive configuration tool. Consider storing configuration options in isolated storage, using per-user isolation.

Programmers should visit the manifold.net website for any supplemental documentation or example implementations, if any are made available in the future.

Geocoding Data Sources
Extensions
Image Server Interface
Manifold Geocoding Servers
Street Address Geocoding
The Manifold Image Server interface is a .NET interface used with image server modules. Image server modules connect to image data sources and expose their data as image components that can be used together with other components inside Manifold projects. For example, there are image server modules for bringing image data into Manifold from various online mapping services such as Google Maps, Yahoo! Maps or Microsoft Virtual Earth.

A Manifold image server module should include one or more .NET objects exposing the Manifold Image Server interface. Each of the objects should have a public parameterless constructor.

Installing a Manifold image server module consists of installing the .NET assembly that contains .NET objects exposing the Manifold Image Server interface into the Manifold installation folder, and doing the necessary configuration required by the assembly. There is no configuration required on the Manifold side besides copying the assembly into the Manifold installation folder and restarting Manifold.

Connecting to a Manifold image server consists of creating an instance of the particular .NET object, setting its properties, retrieving the dimensions and supplementary information describing the target image, and requesting pixels of the target image by tiles.

An image server can choose to operate at one or more scale levels. The resolution of a particular scale level should be 2 times that of the next available scale level. All tiles have the same width and height, regardless of the scale level. Tile coordinates are required to be non-negative.

Image tiles can be in any of the following formats: BMP, ECW, GIF, J2K (JPEG 2000), JPG, PNG, TGA, TIF.

Images linked via the image server interface will use whatever coordinate system (projection) is returned by the image server module in use. If an invalid coordinate system is returned when linking an image Manifold will use the default coordinate system.

**Interface Specification**

The Manifold Image Server interface includes the following members:

**IServer**

String CoordinateSystem
Get the coordinate system of the image in Manifold XML format.

String DefaultImageType
Get default image type, such as ".jpg" or ".png".

String DefaultURL
Get default URL, such as "http://www.example.com/myserver.asp".

Boolean DownloadTile(Int32 x, Int32 y, Int32 scale, String filename)
Download the specified image tile and save it at the specified location in the file system.

String Error
Get last error message.

IRectangle GetRectPixels(Int32 scale, IRectangleD rect)
Convert the supplied rectangle from the coordinate system of the image to pixels. The XMax property of the returned rectangle should be equal to or greater than the XMin property, same for YMax and YMin. Returning a rectangle of (XMin=500, YMin=500, XMax=599, YMax=549) means that the queried image area is 100 pixels wide and 50 pixels high, at the supplied scale level.

IRectangle GetRectTiles(Int32 scale, IRectangleD rect)
Manifold® System Release 8.00 User Manual

Convert the supplied rectangle from the coordinate system of the image to tiles. The XMax property
of the returned rectangle should be equal to or greater than the XMin property, same for YMax and
YMin. Returning a rectangle of (XMin=5, YMin=5, XMax=7, YMax=5) means that the queried image
area is 3 tiles wide and 1 tile high, at the supplied scale level.
String Name
Get the unique name of the image server module. Only alphanumeric characters, spaces, and ".", "", ":", "_", "<", ">", "(", ")", "[", "]", "{", "}", "?", "!", "~", "@", "#", "$", "%", "^", "&", "|" characters are
permitted.
String ProxyAddress
Get or set the address of the proxy server.
String ProxyPassword
Get or set the password for use with the proxy server.
String ProxyUserName
Get or set the user name for use with the proxy server.
Boolean ReverseY
Return True if the pixels and tiles with smaller values of the Y coordinate are on top of those with
larger values of the Y coordinate (the Y axis points down), and False otherwise.
Int32 ScaleHi
Get the least detailed scale. Should return a value equal to or larger than ScaleLo.
Int32 ScaleLo
Get the most detailed scale. Should return a value equal to or less than ScaleHi.
String ScaleNames
Get names of scales, from most detailed to least detailed, separated by commas, for example, "1
meter,2 meters".
Int32 TileSizeX
Get the width of a single tile, in pixels.
Int32 TileSizeY
Get the height of a single tile, in pixels.
String URL
Get or set the URL for the target image.
(Supplementary interfaces)
IRectangle
Int32 XMax
Get maximum X coordinate.
Int32 XMin
Get minimum X coordinate.
Int32 YMax
Get maximum Y coordinate.

2516


Int32 YMin
Get minimum Y coordinate.

IRectangleD

Double XMax
Get maximum X coordinate.

Double XMin
Get minimum X coordinate.

Double YMax
Get maximum Y coordinate.

Double YMin
Get minimum Y coordinate.

The definition of the main Image Server interface and supplementary interfaces resides in Manifold.ImageServer.dll.

All interfaces are defined in the Manifold.ImageServer namespace.

Notes

Implement all members of the Manifold Image Server interface, or the image server module will not be functional. Pay close attention to the meaning of each property and method.

Make sure to name your image server module in a unique way. A common technique is to use the name of your company or project as part of the name for an image server module, for example, Acme Corp Web Map. Do not use any characters that are not explicitly permitted.

Limit the amount of memory used by your image server module to a minimum. There is no need to cache image data, since Manifold already implements caching.

Play well with proxy servers. Do not ignore the values of the ProxyXxx properties supplied by Manifold.

Design your image server module to operate with minimal permissions. At the very least, your module should operate in the context of a normal user account. It is frequently beneficial to declare the permissions required by the module via .NET mechanisms, for use in limited-permission environments.

Design your image server module so it does not require any configuration. If you want the user to be able to customize the operation of the module, provide an interactive configuration tool. Consider storing configuration options in isolated storage, using per-user isolation.

Programmers should also visit the manifold.net website for any supplemental documentation or example implementations, if any are made available in the future.

Programming Reference

For general information on programming Manifold, see the Programming Manifold topic as well as the Scripts and Forms topics.

The Scripting Reference topic provides a reference list of constants, objects and controls information.
Scripting Reference

The topics for many objects will include an Obtained From section at the end of the topic that is a reverse index showing how to obtain that object.

A fairly frequent situation is to know we would like to use a method but we might not know how to get to the object in which that method is implemented. For example we might know that we need to call Intersect but we do not know what to call to use to obtain a GeomSet object which implements the Intersect method. The Obtained From section provides a guide to the objects and methods used to create or otherwise obtain a GeomSet object.

All COM objects exposed by Manifold use apartment-model threading.

Notes

All .NET assemblies (including Manifold.Interop) are installed into the global assembly cache to facilitate reuse.

A .NET script invoked in the context of a web site can access the Document property of the Context object.

A .NET script can access the running script component using the Script property of the Context object. If the script is an add-in script, both the Script and the Document properties of the Context object return null values.

A non-.NET script can access the global Script object, which represents the running script, and the global Document object, which represents the document containing the running script. If the script is an add-in script, both the Script and the Document objects are empty.

New releases of Manifold may introduce new formatting styles. The /alist command line option provides a handy way for programmers to get a comprehensive list of all area, label, line and point styles available and their names.
Constants

Border Constants

Printing borders.

Values

BorderDouble

Double line border.

BorderNone

No border.

BorderSingle

Single line border.

CameraTypeWalk
Walking camera (bounded to surface).

See Also

Scripting Reference
ChannelInterleaving Constants
Channel interleaving options used in image converters (multichannel imports only).

Values

BIL
Line interleaving. Multiple channels are combined at line level.

BIP
Pixel interleaving. Multiple channels are combined at pixel level.

BSQ
Channel interleaving. Multiple channels are stored after each other.

Scripting Reference
**ColumnAlign Constants**
Alignment options used in table columns.

**Values**

- **ColumnAlignCenter**
  - Column text is centered.

- **ColumnAlignLeft**
  - Column text is aligned to left.

- **ColumnAlignRight**
  - Column text is aligned to right.

**See Also**

Scripting Reference
**ColumnCategory Constants**
Table column categories.

**Values**

**ColumnCategoryDss**
Column is computed by DSS engine (rank column).

**ColumnCategoryForeign**
Column is mapped from another table.

**ColumnCategoryIntrinsic**
Column is an intrinsic property of respective object.

**ColumnCategoryLink**
Column is linked from the external OLEDB data source.

**ColumnCategoryMask**
Column stores record mask.

**ColumnCategoryNative**
Column is native.

**ColumnCategoryScript**
Column is computed by the script (active column).

**ColumnCategorySql**
Column is computed by the query engine.

**See Also**

Scripting Reference
ColumnFlag Constants
Flags used in types of table columns. For possible column types see ColumnType Constants.

Values

ColumnFlagAChar
ANSI character.

ColumnFlagBoolean
Boolean type modifier.

ColumnFlagCurrency
Currency.

ColumnFlagFloat32
Single precision floating-point number.

ColumnFlagFloat64
Double precision floating-point number.

ColumnFlagInt16
16 bit integer number.

ColumnFlagInt32
32 bit integer number.

ColumnFlagInt8
8 bit integer number.

ColumnFlagLatitude
Latitude type modifier.

ColumnFlagLongitude
Longitude type modifier.

ColumnFlagPercent
Percentage type modifier.

ColumnFlagTime
Date and time.

ColumnFlagUnsigned
Unsigned type modifier.

ColumnFlagUrl
URL type modifier.

ColumnFlagVector
Vector type modifier.

ColumnFlagWChar
Unicode character.

Scripting Reference
**ColumnFormatNeg Constants**
Formatting options for negative values.

**Values**

- FormatNegBracketBuckSpaceValueBracket
  $(2.345)$

- FormatNegBracketBuckValueBracket
  $(2.345)$

- FormatNegBracketValueBracket
  (2.345)

- FormatNegBracketValueBuckBracket
  (2.345$)

- FormatNegBracketValueSpaceBuckBracket
  (2.345 $)

- FormatNegBuckMinusValue
  $-2.345$

- FormatNegBuckSpaceMinusValue
  $-2.345$

- FormatNegBuckSpaceValueMinus
  $2.345-$

- FormatNegBuckValueMinus
  $2.345-$

- FormatNegDefault
  Default formatting set in Regional Options.

- FormatNegMinusBuckSpaceValue
  -$2.345$

- FormatNegMinusBuckValue
  -$2.345$

- FormatNegMinusSpaceValue
  -2.345

- FormatNegMinusValue
  -2.345

- FormatNegMinusValueBuck

FormatNegValueMinusSpaceBuck
2.345- $

FormatNegValueSpaceBuckMinus
2.345 $-

FormatNegValueSpaceMinus
2.345 -

See Also

Scripting Reference
ColumnFormatPos Constants
Formatting options for positive values.

Values

FormatPosBuckSpaceValue
$ 2.345

FormatPosBuckValue
$2.345

FormatPosDefault
Default formatting set in Regional Options.

FormatPosValueBuck
2.345$

FormatPosValueSpaceBuck
2.345 $
**ColumnType Constants**

Types of table columns. Each type is a combination of one or more of the ColumnFlag Constants.

**Values**

ColumnTypeAChar
ANSI character.

ColumnTypeAText
ANSI text (variable-length or fixed-length).

ColumnTypeBinary
Binary data (variable-length or fixed-length).

ColumnTypeBoolean
Boolean value.

ColumnTypeCoordSys
Coordinate system.

ColumnTypeCurrency
Currency.

ColumnTypeFloat32
Single precision floating-point number.

ColumnTypeFloat64
Double precision floating-point number.

ColumnTypeGeom
Geometric shape.

ColumnTypeGeomSDE
Geometric shape in ESRI SDE format.

ColumnTypeGeomSHP
Geometric shape in ESRI SHP format.

ColumnTypeGeomWKB
Geometric shape in OpenGIS WKB format.

ColumnTypeInt16
16 bit integer number.

ColumnTypeInt16U
Unsigned 16 bit integer number.

ColumnTypeInt32
32 bit integer number.

ColumnTypeInt32U
Unsigned 32 bit integer number.
ColumnTypeInt8
  8 bit integer number.

ColumnTypeInt8U
  Unsigned 8 bit integer number.

ColumnTypeLatitude
  Latitude value.

ColumnTypeLongitude
  Longitude value.

ColumnTypePercentage
  Percentage value.

ColumnTypeTime
  Date and time value.

ColumnTypeURL
  URL string.

ColumnTypeWChar
  Unicode character.

ColumnTypeWText
  Unicode string.

See Also

Scripting Reference

**ComponentType Constants**
Types of components within the map file.

**Values**

- ComponentChart
  Chart.

- ComponentComments
  Comments.

- ComponentDrawing
  Drawing.

- ComponentElevation
  Elevation.

- ComponentFolder
  Folder.

- ComponentForm
  Form.

- ComponentImage
  Image.

- ComponentLabels
  Labels.

- ComponentLayout
  Layout.

- ComponentMap
  Map.

- ComponentNull
  Invalid value. Typically used in initialization.

- ComponentPalette
  Palette.

- ComponentProfile
  Profile.

- ComponentQuery
  Query.

- ComponentScript
  Script.

- ComponentSurface
  Surface.
ComponentTable
   Table.

ComponentTerrain
   Terrain.

ComponentTheme
   Theme.

ComponentZones
   Zones.

See Also

Scripting Reference
**ComputationMode Constants**

Computation mode of an active column.

**Values**

- **ComputationModeCachedUpdateable**
  Computes active column on demand. Caches computed values and resets cache whenever script component is changed.

- **ComputationModeCached**
  Computes active column on demand. Caches computed values.

- **ComputationModeManual**
  Computes active column on user request.

- **ComputationModeUncached**
  Computes active column on demand. Does not cache values.

**See Also**

Scripting Reference
**ConvertPolicy Constants**
Import or export policies used in converters.

**Values**

ConvertAll
Import or export all items affected by policy.

ConvertNone
Import or export none of items affected by policy.

ConvertSome
Import or export explicit set of items supplied with ConverterItemSet.

**See Also**

Scripting Reference
**ConvertPrompt Constants**
Prompt options used in converters.

**Values**

- **PromptAlways**
  Always display conversion dialog.

- **PromptDefault**
  Display conversion dialog according to options.

- **PromptNone**
  Never display conversion dialog.

**See Also**

Scripting Reference
CoordinateBand Constants
Coordinate band types used in printing.

Values

CoordinateBandLatLon
Print latitude/longitude coordinates.

CoordinateBandMetric
Print native coordinates.

CoordinateBandNone
Do not print any coordinates.

See Also

Scripting Reference
CoordinateSystemParameterType Constants
Types of coordinate system parameters.

Values

ParameterLatitude
Latitude. Parameter value is in degrees.

ParameterLength
Length. Parameter value is in meters.

ParameterLongitude
Longitude. Parameter value is in degrees.

ParameterOther
Other.

See Also

Scripting Reference
DSSAtomType Constants
Types of atomic expressions used in rank columns.

Values

DSSAtomTypeAverage
Ranks average values higher than smaller or greater ones.

DSSAtomTypeCurve
Ranks values according to user-supplied curve.

DSSAtomTypeHigh
Ranks greater values higher than smaller values.

DSSAtomTypeLow
Ranks smaller values higher than greater values.

DSSAtomTypeTwoPoints
Ranks values according to a curve defined by two points.

See Also

Scripting Reference
**DSSHedge Constants**
Hedges applied to criteria in rank columns.

**Values**

DSSHedgeAbove
Ranks greater values higher than smaller values.

DSSHedgeBelow
Ranks smaller values higher than greater values.

DSSHedgeExtremely
Greatly increases selectiveness of subject criterion.

DSSHedgeNone
Has no effect on subject criterion.

DSSHedgeSlightly
Decreases selectiveness of subject criterion.

DSSHedgeSomewhat
Greatly decreases selectiveness of subject criterion.

DSSHedgeVery
Increases selectiveness of subject criterion.

**See Also**

Scripting Reference
**DSSJunction Constants**
Junctions applied to criteria in rank columns.

**Values**

DSSJunctionAnd
AND junction.

DSSJunctionNone
No junction (used for the last criterion).

DSSJunctionOr
OR junction.

**See Also**

Scripting Reference
FormatType Constants
Type of formatting.

Values

FormatTypeNone
Unknown / uninitialized.

FormatTypeColor
Color.

FormatTypeAreaSize
Area size.

FormatTypeAreaStyle
Area style.

FormatTypeLabelRotation
Label rotation angle.

FormatTypeLabelSize
Label size.

FormatTypeLabelStyle
Label style.

FormatTypeLineSize
Line size.

FormatTypeLineStyle
Line style.

FormatTypePointRotation
Point rotation angle.

FormatTypePointSize
Point size.

FormatTypePointStyle
Point style.

See Also

Scripting Reference
GeocodeLevel Constants
Geocoding levels.

Values

GeocodeLevelBuilding
Location is a building.

GeocodeLevelCity
Location is a city (place) centroid.

GeocodeLevelNoLocation
Location is not available.

GeocodeLevelStreet
Location is a street centroid.

GeocodeLevelZip
Location is a zip centroid.

See Also

Scripting Reference
GeocodeStatus Constants
Results of a geocoding operation.

Values

GeocodeCriticalError
Critical error.

GeocodeSuccess
Success.

GeocodeUnknownBuilding
Unknown building.

GeocodeUnknownStreet
Unknown street name, no similar names.

GeocodeUnknownStreetMisspelling
Unknown street name, possible misspelling.

GeocodeUnknownZip
Unknown zip code.

See Also

Scripting Reference
**GeomArea, GeomLine and GeomPoint Constants**
Types of geometric entities.

**Values**

GeomArea
Area (polygon).

GeomLine
Line (polyline).

GeomPoint
Point.

**See Also**

Scripting Reference
**ImageType Constants**
Types of image components.

**Values**

ImageTypeGrayscale
Grayscale image.

ImageTypePalette
Palette image.

ImageTypeRGB
Color image.

ImageTypeRGBA
Color image with alpha channel.

**See Also**

Scripting Reference
JpegCompression Constants
JPEG compression methods used in converters.

Values

JpegCompressionBaseline
Baseline compression.

JpegCompressionBaselineOptimized
Optimized baseline compression.

JpegCompressionProgressive
Progressive scans.

See Also

Scripting Reference
**JpegQuality Constants**

JPEG quality values used in converters.

**Values**

JpegQualityHigh
High quality.

JpegQualityLow
Low quality.

JpegQualityMax
Maximum possible quality.

JpegQualityMed
Medium quality.

**See Also**

Scripting Reference
LabelAlignMulti Constants
Alignment options for multiline labels.

Values

LabelAlignMultiCenter
Multiple lines of text are centered.

LabelAlignMultiJustify
Multiple lines of text are justified with whitespace.

LabelAlignMultiLeft
Multiple lines of text are aligned to left side.

LabelAlignMultiRight
Multiple lines of text are aligned to right side.

See Also

Scripting Reference
**LabelAlignX Constants**
Horizontal alignment options for labels.

**Values**

LabelAlignXCenter
Label is centered over the tie point.

LabelAlignXLeft
Label is at the left of tie point.

LabelAlignXRight
Label is at the right of tie point.

**See Also**

Scripting Reference
LabelAlignY Constants
Vertical alignment options for labels.

Values

LabelAlignYBottom
Label is at the bottom of tie point.

LabelAlignYCenter
Label is centered vertically.

LabelAlignYTop
Label is at the top of tie point.

See Also

Scripting Reference
LayoutBorder Constants
Layout borders.

Values

LayoutBorderCoordinates
Coordinates given by the user.

LayoutBorderCoordinatesGraticule
Coordinates taken from graticule.

LayoutBorderCoordinatesGrid
Coordinates taken from grid.

LayoutBorderNone
No border.

LayoutBorderThick
Thick (1 point) border.

LayoutBorderThin
Thin (1/20 point) border.

See Also

Scripting Reference
**LayoutPaging Constants**

Layout paging modes.

**Values**

- **LayoutPagingContinuous**
  - Continuous paging mode.

- **LayoutPagingIndividual**
  - Individual paging mode.

**See Also**

Scripting Reference
LayoutScope Constants
Layout scopes.

Values

LayoutScopeAll
All objects or pixels.

LayoutScopeBox
Fixed area whose rectangle is specified by the ScopeArea property. You can also read or write the center / scale of the area using the ScopeCenter and ScopeScale properties.

LayoutScopeLayer
Layer specified by the ScopeDetail property.

LayoutScopeScale
Fixed area whose center / scale is specified by the ScopeCenter and ScopeScale properties. You can also read or write the area using the ScopeArea property.

LayoutScopeSelection
Selection.

LayoutScopeSavedSelection
Saved selection specified by the ScopeDetail property.

LayoutScopeView
View specified by the ScopeDetail property.

See Also

Scripting Reference
**LayoutState Constants**
State of a layout entry option like graticule or legend.

**Values**

- **LayoutStateCustom**
  Option is overridden by the layout entry (applies to background).

- **LayoutStateOff**
  Option is turned off.

- **LayoutStateOn**
  Option is turned on.

- **LayoutStateOnWithComponent**
  Option is controlled by the component ("auto").

**See Also**

Scripting Reference
**LayoutType Constants**
Type of layout entry.

**Values**

LayoutTypeBody
Owner component.

LayoutTypeComponent
Arbitrary component.

LayoutTypeLegend
Legend (should be bound to some other layout entry).

LayoutTypeLineHorz
Horizontal line.

LayoutTypeLineVert
Vertical line.

LayoutTypeNorthArrow
North arrow (should be bound to some other layout entry).

LayoutTypeNull
Invalid type.

LayoutTypeRect
Rectangle.

LayoutTypeScaleBar
Scale bar (should be bound to some other layout entry).

LayoutTypeText
Text (can be bound to some other layout entry).

**See Also**

Scripting Reference
LegendType Constants
Legend types.

Values

LegendStandard
Standard legend.

See Also

Scripting Reference
LightingDirection Constants
Lighting directions used in surfaces and terrains.

Values

DirectionEast
Sun shines from east.

DirectionNone
Invalid value. Typically used in initialization.

DirectionNorth
Sun shines from north.

DirectionNorthEast
Sun shines from north-east.

DirectionNorthWest
Sun shines from north-west.

DirectionSouth
Sun shines from south.

DirectionSouthEast
Sun shines from south-east.

DirectionSouthWest
Sun shines from south-west.

DirectionWest
Sun shines from west.

See Also

Scripting Reference
LinkEditMode Constants
Editing modes used by linked components.

Values

LinkEditModeNone
Invalid editing mode.

LinkEditModeOverwrite
Editing the component overwrites changes made by others.

LinkEditModeReadOnly
The component is read-only. No editing is possible.

LinkEditModeReview
Editing the component detects changes made by others and resolves editing conflicts using the Review pane.

See Also

Scripting Reference
MapServerRenderFormat Constants
Rendering format used by the MapServer object.

Values

MapServerRenderFormatDefault
Default render format (PNG).

MapServerRenderFormatGif
GIF render format.

MapServerRenderFormatJpeg
JPEG render format, supports specifying rendering quality.

MapServerRenderFormatPng
PNG render format.

See Also

Scripting Reference
MessageBoxResult Constants
Status codes returned by the MessageBox and MessageBoxEx methods of the Application object.

Values

MessageBoxResultAbort
Abort button has been pressed.

MessageBoxResultCancel
Cancel button has been pressed.

MessageBoxResultIgnore
Ignore button has been pressed.

MessageBoxResultNo
No button has been pressed.

MessageBoxResultOk
OK button has been pressed.

MessageBoxResultRetry
Retry button has been pressed.

MessageBoxResultYes
Yes button has been pressed.

See Also

Scripting Reference
MessageBoxType Constants
Icons and buttons used by message boxes invoked by the MessageBox and MessageBoxEx methods of the Application object. Individual constants can be combined using the binary "or" operator, or, in case of combining a button or a set of buttons and an icon, using the ordinary addition operator.

Values

MessageBoxTypeAbortRetryIgnore
Abort, Retry and Ignore buttons.

MessageBoxTypeApplModal
The user has to close the message box before continuing to work with the application.

MessageBoxTypeCancelTryContinue
Cancel, Try and Continue buttons.

MessageBoxTypeDefaultButton1
Make first button the default button.

MessageBoxTypeDefaultButton2
Make second button the default button.

MessageBoxTypeDefaultButton3
Make third button the default button.

MessageBoxTypeDefaultButton4
Make fourth button the default button.

MessageBoxTypeDefaultDesktopOnly
Display the message box only on the default desktop.

MessageBoxTypeHelp
Help button.

MessageBoxTypeIconAsterisk
Information icon.

MessageBoxTypeIconError
Stop icon.

MessageBoxTypeIconExclamation
Exclamation icon.

MessageBoxTypeIconHand
Stop icon.

MessageBoxTypeIconInformation
Information icon.

MessageBoxTypeIconQuestion
Question icon.

MessageBoxTypeIconStop
Stop icon.

MessageBoxTypeIconWarning
   Exclamation icon.

MessageBoxTypeNoFocus
   Display the message box without making it focused.

MessageBoxTypeOk
   OK button.

MessageBoxTypeOkCancel
   OK and Cancel buttons.

MessageBoxTypeRetryCancel
   Retry and Cancel buttons.

MessageBoxTypeRight
   Right-justify message box text.

MessageBoxTypeRTLReading
   Force right-to-left reading order.

MessageBoxTypeSetForeground
   Bring the message box window to the foreground.

MessageBoxTypeSystemModal
   The user has to close the message box before continuing to work with the application. Makes the message box window topmost.

MessageBoxTypeTaskModal
   The user has to close the message box before continuing to work with the application. Disables all top-level windows belonging to the thread that launched the message box.

MessageBoxTypeTopmost
   Make the message box window topmost.

MessageBoxTypeYesNo
   Yes and No buttons.

MessageBoxTypeYesNoCancel
   Yes, No and Cancel buttons.

See Also

Scripting Reference
NorthArrowType Constants

North arrow types.

Values

NorthArrowCompass
Compass pointing North, South, East and West.

NorthArrowCompassN
Compass pointing North, South, East and West with a letter N.

NorthArrowCompassNS
Compass pointing North, South, East and West with letters N and S.

NorthArrowCompassNESW
Compass pointing North, South, East and West with letters N, S, E and W.

NorthArrowDouble
Arrow pointing North and South.

NorthArrowDoubleN
Arrow pointing North and South with a letter N.

NorthArrowDoubleNS
Arrow pointing North and South with letters N and S.

NorthArrowDoubleShadow
Arrow pointing North and South with a shadow.

NorthArrowDoubleShadowN
Arrow pointing North and South with a letter N and a shadow.

NorthArrowDoubleShadowNS
Arrow pointing North and South with letters N and S and a shadow.

NorthArrowHalfHarpoon
Simple "half-harpoon" arrow pointing North.

NorthArrowHalfHarpoonN
Simple "half-harpoon" arrow pointing North with a letter N.

NorthArrowHalfHarpoonNS
Simple "half-harpoon" arrow pointing North with letters N and S.

NorthArrowHarpoon
Simple "harpoon" arrow pointing North.

NorthArrowHarpoonN
Simple "harpoon" arrow pointing North with a letter N.

NorthArrowHarpoonNS
Simple "harpoon" arrow pointing North with letters N and S.
NorthArrowNaval
Naval arrow pointing North and South.

NorthArrowNavalN
Naval arrow pointing North and South with a letter N.

NorthArrowNavalNS
Naval arrow pointing North and South with letters N and S.

NorthArrowRose
Rose compass pointing North, South, East and West.

NorthArrowRoseArrow
North arrow from rose compass.

NorthArrowRoseArrowN
North arrow from rose compass with a letter N.

NorthArrowRoseN
Rose compass pointing North, South, East and West with a letter N.

NorthArrowRoseNS
Rose compass pointing North, South, East and West with letters N and S.

NorthArrowRoseNESW
Rose compass pointing North, South, East and West with letters N, S, E and W.

NorthArrowRoseQuad
Rose compass without intermediate junctions pointing North, South, East and West.

NorthArrowRoseQuadN
Rose compass without intermediate junctions pointing North, South, East and West with a letter N.

NorthArrowRoseQuadNS
Rose compass without intermediate junctions pointing North, South, East and West with letters N and S.

NorthArrowRoseQuadNESW
Rose compass without intermediate junctions pointing North, South, East and West with letters N, S, E and W.

NorthArrowRoseTwin
North and South arrows from rose compass without intermediate junctions.

NorthArrowRoseTwinN
North and South arrows from rose compass without intermediate junctions with a letter N.

NorthArrowRoseTwinNS
North and South arrows from rose compass without intermediate junctions with letters N and S.

NorthArrowSingle
Arrow pointing North.

NorthArrowSingleN
Arrow pointing North with a letter N.

NorthArrowSingleShadow
Arrow pointing North with a shadow.

NorthArrowSingleShadowN
Arrow pointing North with a letter N and a shadow;

See Also

Scripting Reference
**Object Type Constants**
Types of drawing objects.

**Values**

ObjectArea
Area.

ObjectLine
Line.

ObjectPoint
Point.

**See Also**

Scripting Reference
PageIndicator Constants
Types of page indicator used in printing.

Values

PageIndicatorGraphic
Graphic page indicator.

PageIndicatorNone
No page indicator.

PageIndicatorText
Textual page indicator (eg. "A1").

See Also

Scripting Reference
PointUSNGPrecision Constants
USNG precision levels.

Values

PointUSNGPrecision10km
10 kilometers precision.

PointUSNGPrecision1km
1 kilometer precision.

PointUSNGPrecision100m
100 meters precision.

PointUSNGPrecision10m
10 meters precision.

PointUSNGPrecision1m
1 meter precision.

See Also

**QueryType Constants**
Query types.

**Values**

- **QueryTypeAlterTable**
  ALTER TABLE query.

- **QueryTypeCreateDrawing**
  CREATE DRAWING query.

- **QueryTypeCreateView**
  CREATE VIEW query.

- **QueryTypeCreateTable**
  CREATE TABLE query.

- **QueryTypeCrossTable**
  TRANSFORM query.

- **QueryTypeDelete**
  DELETE query.

- **QueryTypeDropTable**
  DROP TABLE query.

- **QueryTypeDropView**
  DROP VIEW query.

- **QueryTypeInsertInto**
  INSERT INTO query.

- **QueryTypeInvalid**
  Invalid query.

- **QueryTypeSelect**
  SELECT query.

- **QueryTypeSelectInto**
  SELECT INTO query.

- **QueryTypeUpdate**
  UPDATE query.

**See Also**

Scripting Reference
Scope Constants
Scopes within various mapfile components.

Values

AllLabels
All labels (used with labels components).

AllObjects
All objects (used with drawing components).

AllPixels
All pixels (used with image or surface components).

InvisiblePixels
Invisible pixels (used with image or surface components).

Selection
Selected labels, objects or pixels (used with drawing, image, labels or surface components).

See Also

Scripting Reference
**SelectMode Constants**

Selection modes.

**Values**

- **SelectAdd**
  - Addition mode.

- **SelectIntersect**
  - Intersection mode.

- **SelectInvert**
  - Inversion mode.

- **SelectReplace**
  - Replacement mode.

- **SelectSubtract**
  - Subtraction mode.

**See Also**

Scripting Reference
SubtypeAny Constants
Import subtypes.

Values

SubtypeImage
Import data as image.

SubtypeSurface
Import data as surface.

See Also

Scripting Reference
**SubtypeDb Constants**

Subtypes of DB files used in converters.

**Values**

- SubtypeDbParadox3x
  - Paradox 3.x.

- SubtypeDbParadox4x
  - Paradox 4.x.

- SubtypeDbParadox5x
  - Paradox 5.x.

**See Also**

Scripting Reference
**SubtypeDbf Constants**

Subtypes of DBF files used in converters.

**Values**

SubtypeDbfFoxPro
FoxPro.

SubtypeDbfDBase3
dBase III.

SubtypeDbfDBase4
dBase IV.

SubtypeDbfDBase5
dBase V.

**See Also**

Scripting Reference
SubtypeMdb Constants
Subtypes of MDB files used in converters.

Values

SubtypeMdbAccess2000

SubtypeMdbAccess97
Access 97.

Subtypes of TAIF files used in converters.

**Values**

SubtypeTaifLevel1
TAIF Level 1.

SubtypeTaifLevel2
TAIF Level 2.

SubtypeTaifStreetNet
TAIF StreetNet.

**See Also**

Scripting Reference
SubtypeWk Constants
Subtypes of WK files used in converters.

Values

SubtypeWk1
WK1.

SubtypeWk3
WK3.

SubtypeWk4
WK4.

See Also

Scripting Reference
SubtypeXls Constants
Subtypes of XLS files used in converters.

Values

SubtypeXls30
Excel 3.0.

SubtypeXls40
Excel 4.0

SubtypeXls50
Excel 5.0.

SubtypeXls80
Excel 97

See Also

Scripting Reference
**TiffCompression Constants**

TIFF compression options used in converters.

**Values**

- **TiffCompressionJpeg**
  JPEG compression.

- **TiffCompressionLzw**
  LZW compression.

- **TiffCompressionNone**
  No compression.

- **TiffCompressionPackBits**
  PackBits compression.

- **TiffCompressionZip**
  ZIP (deflate) compression.

**See Also**

Scripting Reference
TransferRuleDiv Constants
1 to N transfer rules used in table columns.

Values

TransferDivNone
None.

TransferDivCopy
Copy.

TransferDivEqual
Equal.

TransferDivProportional
Proportional (requires a column).

TransferDivSample
Sample.

See Also

Scripting Reference
TransferRuleMul Constants
N to 1 transfer rules used in table columns.

Values

TransferMulNone
None.

TransferMulAverage
Average.

TransferMulCopy
Copy.

TransferMulCount
Count.

TransferMulMaximum
Maximum.

TransferMulMedian
Median.

TransferMulMinimum
Minimum.

TransferMulSample
Sample.

TransferMulSum
Sum.

See Also

Scripting Reference
**TurnStyle Constants**  
Turn report styles (used with routes).

**Values**

- **TurnStyleNone**  
  No turns.

- **TurnStyleAbsolute**  
  "Turn East" report style.

- **TurnStyleBoth**  
  "Turn Right (East)" report style.

- **TurnStyleRelative**  
  "Turn Right" report style.

**See Also**

- **Analyzer Object**  
  Scripting Reference
**ValueType Constants**

Pixel value types used in image converters.

**Values**

**ValueTypeBit**

1 bit.

**ValueTypeFloat32**

Single precision floating-point number.

**ValueTypeFloat64**

Double precision floating-point number.

**ValueTypeInt16**

16 bit integer.

**ValueTypeInt32**

32 bit integer.

**ValueTypeInt64**

64 bit integer.

**ValueTypeInt8**

8 bit integer.

**ValueTypeUInt16**

Unsigned 16 bit integer.

**ValueTypeUInt32**

Unsigned 32 bit integer.

**ValueTypeUInt64**

Unsigned 64 bit integer.

**ValueTypeUInt8**

Unsigned 8 bit integer.

**See Also**

Scripting Reference
**WindowAlign Constants**
Alignment options for north arrow, scale bar and legend.

**Values**

WindowAlignBottomLeft
Align to bottom left corner of visible area.

WindowAlignBottomRight
Align to bottom right corner of visible area.

WindowAlignNone
No alignment.

WindowAlignTopLeft
Align to top left corner of visible area.

WindowAlignTopRight
Align to top right corner of visible area.

**See Also**
Scripting Reference

Objects

Analyzer Object
Performs spatial analysis and transforms.

Properties

Application Application
Returns application. Read only.

Parent Parent
Returns parent object. Read only.

Methods for Drawings / General Methods

ObjectSet AttachTo(Component context, ObjectSet target, ObjectSet source)
Attaches objects in target object set to objects in source object set using the coordinate system and the location precision of the context component.

ObjectSet AttachToSelf(Component context, ObjectSet target)
Attaches objects in target object set to itself using the coordinate system and the location precision of the context component.

ObjectSet BorderBuffers(Component context, Drawing drawing, ObjectSet target, Number size, String unit)
Creates border buffers of specified size for objects in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing. Unit parameter is optional and can be a Unit object or a unit name.

ObjectSet Boundaries(Component context, Drawing drawing, ObjectSet target)
Creates boundaries for objects in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

ObjectSet BoundedAreas(Component context, Drawing drawing, ObjectSet target)
Creates areas bounded by objects in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

ObjectSet BoundingBoxes(Component context, Drawing drawing, ObjectSet target)
Creates bounding boxes of objects in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

ObjectSet Buffers(Component context, Drawing drawing, ObjectSet target, Number size, String unit)
ObjectSet Buffers(Component context, Drawing drawing, ObjectSet target, Number size, Unit unit)
Creates buffers of specified size for objects in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing. Unit parameter is optional and can be a Unit object or a unit name.

ObjectSet Centroids(Component context, Drawing drawing, ObjectSet target)
Creates centroids of objects in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

ObjectSet CentroidsBox(Component context, Drawing drawing, ObjectSet target)

Creates box centroids (centers of bounding boxes) of objects in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

ObjectSet CentroidsInner(Component context, Drawing drawing, ObjectSet target)

Creates inner centroids of areas (centroids which are guaranteed to stay within areas) in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

ObjectSet CentroidsWeight(Component context, Drawing drawing, ObjectSet target)

Creates weight centroids of objects in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

ObjectSet ClipIntersect(Component context, ObjectSet target, ObjectSet source)

Intersects objects in target object set with objects in source object set using the coordinate system and the location precision of the context component.

ObjectSet ClipSubtract(Component context, ObjectSet target, ObjectSet source)

Subtracts objects in source object set from objects in target object set using the coordinate system and the location precision of the context component.

ObjectSet Clusters(Component context, Drawing drawing, ObjectSet target, Number threshold)

Connects objects in target object set into clusters with specified threshold using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

ObjectSet ConstrainedTriangulation(Component context, Drawing drawing, ObjectSet target)

Creates constrained triangulation of all objects in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

ObjectSet ConstrainedTriangulationAreas(Component context, Drawing drawing, ObjectSet target)

Creates constrained triangulation of all objects in target object set using the coordinate system and the location precision of the context component and creates an area object for each triangle in the specified drawing.

ObjectSet ConstrainedTriangulationLines(Component context, Drawing drawing, ObjectSet target)

Creates constrained triangulation of all objects in target object set using the coordinate system and the location precision of the context component and creates a line object for each triangulation edge in the specified drawing.

AnalyzerValueSet ClustersAssoc(Component context, ObjectSet target, Number threshold)

Connects objects in target object set into clusters with specified threshold using the coordinate system and the location precision of the context component and returns a set of resulting connections.

ObjectSet ClustersZahn(Component context, Drawing drawing, ObjectSet target, Number threshold)

Connects objects in target object set into Zahn clusters with specified threshold using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

AnalyzerValueSet ClustersZahnAssoc(Component context, ObjectSet target, Number threshold)

Connects objects in target object set into Zahn clusters with specified threshold using the coordinate system and the location precision of the context component and returns a set of resulting connections.

ObjectSet CommonBoundingBox(Component context, Drawing drawing, ObjectSet target)

Creates common bounding box of all objects in target object set using the coordinate system and the location precision of the context component and places the new object into specified drawing.

ObjectSet CommonBuffer(Component context, Drawing drawing, ObjectSet target, Number size, String unit)
ObjectSet CommonBuffer(Component context, Drawing drawing, ObjectSet target, Number size, Unit unit)
Creates common buffer of specified size of all objects in target object set using the coordinate system and the location precision of the context component and places the new object into specified drawing. Unit parameter is optional and can be a Unit object or a unit name.

ObjectSet CommonCentroid(Component context, Drawing drawing, ObjectSet target)
Creates common centroid of all objects in target object set using the coordinate system and the location precision of the context component and places the new object into specified drawing.

ObjectSet CommonEnclosingCircle(Component context, Drawing drawing, ObjectSet target)
Creates common enclosing circle of all objects in target object set using the coordinate system and the location precision of the context component and places the new object into specified drawing.

ObjectSet CommonEnclosingRectangle(Component context, Drawing drawing, ObjectSet target)
Creates common enclosing rectangle of all objects in target object set using the coordinate system and the location precision of the context component and places the new object into specified drawing.

ObjectSet ConvexHull(Component context, Drawing drawing, ObjectSet target)
Creates convex hull of all objects in target object set using the coordinate system and the location precision of the context component and places the new object into specified drawing.

ObjectSet Decompose(Component context, ObjectSet target)
Decompose objects in target object set using the coordinate system and the location precision of the context component.

ObjectSet DecomposeToConvexParts(Component context, ObjectSet target)
Decompose objects in target object set into convex parts using the coordinate system and the location precision of the context component.

ObjectSet DecomposeToTriangles(Component context, ObjectSet target)
Decompose objects in target object set into triangles using the coordinate system and the location precision of the context component.

ObjectSet DistanceNetwork(Component context, Drawing drawing, ObjectSet target, Number threshold, String unit)
ObjectSet DistanceNetwork(Component context, Drawing drawing, ObjectSet target, Number threshold, Unit unit)
Connects objects in target object set into distance network with specified distance threshold using the coordinate system and the location precision of the context component and places the new objects into specified drawing. Unit parameter is optional and can be a Unit object or a unit name.

AnalyzerValueSet DistanceNetworkAssoc(Component context, ObjectSet target, Number threshold, String unit)
AnalyzerValueSet DistanceNetworkAssoc(Component context, ObjectSet target, Number threshold, Unit unit)
Connects objects in target object set into distance network with specified distance threshold using the coordinate system and the location precision of the context component and returns a set of resulting connections. Unit parameter is optional and can be a Unit object or a unit name.

AnalyzerValueSetColumn District (ObjectSet areas, Column balance, Number districts, Number threshold)
Splits set of areas to a given number of districts balancing given column. Column can be supplied directly or by its ID or name. Threshold is a maximum possible distance in native coordinate system units at which the areas can connect and is optional. Returns a set of associations between areas and their district numbers.

AnalyzerValueSetColumn DistrictAdv (ObjectSet areas, Column balance, String districts, Column startWith)
Splits set of areas to districts balancing given column. Column and StartWith columns can be supplied directly or by their IDs or names. Districts contains relative weights of districts separated by commas. There can be no negative or zero weights and there should be at least two weights. StartWith contains initial district information and is optional. Returns a set of associations between areas and their district numbers. Requires Business Tools extension.
AnalyzerValueSetColumn DistrictAdvGeom(ObjectSet areas, Column balance, String districts, Column startWith, Number balancing, Number compactness)
Splits set of areas to districts balancing given column. Balance and StartWith columns can be supplied directly or by their IDs or names. Districts contains relative weights of districts separated by commas. There can be no negative or zero weights and there should be at least two weights. StartWith contains initial district information and is optional. Balancing and Compactness contain relative preferences for more balanced districts or more compact districts. Returns a set of associations between areas and their district numbers. Requires BusinessTools extension.

Geom DriveTimeZone(ObjectSet roads, Object center, Column length, Column speed, Number speedOverLand, Number time)
Geom DriveTimeZone(ObjectSet roads, ObjectSet centers, Column length, Column speed, Number speedOverLand, Number time)
Creates a drive-time zone using a road network and a single center or a set of centers. Length and Speed columns can be supplied directly or by their IDs or names. SpeedOverLand is a speed of movement “across” the roads. Requires Business Tools extension.

Geom DriveTimeZoneBuffer(ObjectSet roads, Object center, Column length, Column speed, Number time, Number buffer, Unit bufferUnit)
Geom DriveTimeZoneBuffer(ObjectSet roads, ObjectSet centers, Column length, Column speed, Number time, Number buffer, Unit bufferUnit)
Creates a drive-time buffer using a road network and a single center or a set of centers. Length and Speed columns can be supplied directly or by their IDs or names. Requires Business Tools extension.

Geom DriveTimeZoneConvex(ObjectSet roads, Object center, Column length, Column speed, Number time)
Geom DriveTimeZoneConvex(ObjectSet roads, ObjectSet centers, Column length, Column speed, Number time)
Creates a drive-time hull using a road network and a single center or a set of centers. Length and Speed columns can be supplied directly or by their IDs or names. Requires Business Tools extension.

ObjectSet EnclosingCircles(Component context, Drawing drawing, ObjectSet target)
Creates enclosing circles for objects in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

ObjectSet EnclosingRectangles(Component context, Drawing drawing, ObjectSet target)
Creates enclosing rectangles for objects in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

ObjectSet Explode(Component context, ObjectSet target)
Decompose lines in target object set to segments using the coordinate system and the location precision of the context component.

ObjectSet FarthestNeighbor(Component context, Drawing drawing, ObjectSet target, ObjectSet source)
Connects each object in source object set with its farthest neighbor in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

AnalyzerValueSet FarthestNeighborAssoc(Component context, ObjectSet target, ObjectSet source)
Connects each object in source object set with its farthest neighbor in target object set using the coordinate system and the location precision of the context component and returns a set of resulting connections.

ObjectSet FarthestNeighborSymm(Component context, Drawing drawing, ObjectSet target, ObjectSet source)
Connects each object in source object set with its symmetric farthest neighbor in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

AnalyzerValueSet FarthestNeighborSymmAssoc(Component context, ObjectSet target, ObjectSet source)
Connects each object in source object set with its symmetric farthest neighbor in target object set using the coordinate system and the location precision of the context component and returns a set of resulting connections.
ObjectSet FarthestPair(Component context, Drawing drawing, ObjectSet target)
Connects farthest pair of objects in target object set using the coordinate system and the location precision of
the context component and places the new object into specified drawing.

AnalyzerValueSet FarthestPairAssoc(Component context, ObjectSet target)
Connects farthest pair of objects in target object set using the coordinate system and the location precision of
the context component and returns the resulting connection.

ObjectSet FlipHorizontally(Component context, ObjectSet target)
Flips objects in target object set horizontally using the coordinate system and the location precision of the
context component.

ObjectSet FlipVertically(Component context, ObjectSet target)
Flips objects in target object set vertically using the coordinate system and the location precision of the context
component.

ObjectSet GabrielNetwork(Component context, Drawing drawing, ObjectSet target)
Connects objects in target object set into Gabriel network using the coordinate system and the location precision
of the context component and places the new objects into specified drawing.

AnalyzerValueSet GabrielNetworkAssoc(Component context, ObjectSet target)
Connects objects in target object set into Gabriel network using the coordinate system and the location precision
of the context component and returns a set of resulting connections.

ObjectSet InnerBuffers(Component context, Drawing drawing, ObjectSet target, Number size, String unit)
ObjectSet InnerBuffers(Component context, Drawing drawing, ObjectSet target, Number size, Unit unit)
Creates inner buffers of specified size for objects in target object set using the coordinate system and the
location precision of the context component and places the new objects into specified drawing. Unit parameter
is optional and can be a Unit object or a unit name.

ObjectSet IntersectLines(Component context, ObjectSet target)
Intersects lines in target object set using the coordinate system and the location precision of the context
component.

ObjectSet IntersectionPoints(Component context, Drawing drawing, ObjectSet target)
Creates intersection points of lines in target object set using the coordinate system and the location precision of
the context component and places the new objects into specified drawing.

ObjectSet JoinLines(Component context, Drawing drawing, ObjectSet target)
Joins lines in target object set using the coordinate system and the location precision of the context component
and places the new objects into specified drawing.

ObjectSet MoveHorizontally(Component context, ObjectSet target, Number size, String unit)
ObjectSet MoveHorizontally(Component context, ObjectSet target, Number size, Unit unit)
Moves objects in target object set horizontally by specified distance using the coordinate system and the location
precision of the context component. Unit parameter is optional and can be a Unit object or a unit name.

ObjectSet MoveVertically(Component context, ObjectSet target, Number size, String unit)
ObjectSet MoveVertically(Component context, ObjectSet target, Number size, Unit unit)
Moves objects in target object set vertically by specified distance using the coordinate system and the location
precision of the context component. Unit parameter is optional and can be a Unit object or a unit name.

ObjectSet NearestNeighbor(Component context, Drawing drawing, ObjectSet target, ObjectSet source)
Connects each object in source object set with its nearest neighbor in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

AnalyzerValueSet NearestNeighborAssoc(Component context, ObjectSet target, ObjectSet source)

Connects each object in source object set with its nearest neighbor in target object set using the coordinate system and the location precision of the context component and returns a set of resulting connections.

ObjectSet NearestNeighborSymm(Component context, Drawing drawing, ObjectSet target, ObjectSet source)

Connects each object in source object set with its symmetric nearest neighbor in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

AnalyzerValueSet NearestNeighborSymmAssoc(Component context, ObjectSet target, ObjectSet source)

Connects each object in source object set with its symmetric nearest neighbor in target object set using the coordinate system and the location precision of the context component and returns a set of resulting connections.

ObjectSet NearestPair(Component context, Drawing drawing, ObjectSet target)

Connects nearest pair of objects in target object set using the coordinate system and the location precision of the context component and places the new object into specified drawing.

AnalyzerValueSet NearestPairAssoc(Component context, ObjectSet target)

Connects nearest pair of objects in target object set using the coordinate system and the location precision of the context component and returns the resulting connection.

ObjectSet NodePoints(Component context, Drawing drawing, ObjectSet target)

Creates node points for lines in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

ObjectSet NormalizeMetric(Component context, ObjectSet target)

Normalizes metric of objects in target object set using the coordinate system and the location precision of the context component.

ObjectSet NormalizeTopology(Component context, ObjectSet target)

Normalizes topology of objects in target object set using the coordinate system and the location precision of the context component.

Route OptimalRoute(ObjectSet locations, ObjectSet roads, Column length, Column speed, Boolean split, Object start, Object finish)

Locates optimal route between given locations using given roads. There should be at least two locations and at least one road. Length and Speed columns can be supplied directly or by their IDs or names. Split controls whether the roads are split at intersections and locations (the default) or not. Start and finish parameters are optional. Returns a route. Requires Business Tools extension.

ObjectSet Points(Component context, Drawing drawing, ObjectSet target)

Creates inflection points of objects in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

ObjectSet RelativeNeighborhoodNetwork(Component context, Drawing drawing, ObjectSet target)

Connects objects in target object set into relative neighborhood network using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

AnalyzerValueSet RelativeNeighborhoodNetworkAssoc(Component context, ObjectSet target)

Connects objects in target object set into relative neighborhood network using the coordinate system and the location precision of the context component and returns a set of resulting connections.

ObjectSet RemoveDuplicates(Component context, ObjectSet target)
Removes duplicate objects in target object set using the coordinate system and the location precision of the
correct component.

ObjectSet ReverseLines(Component context, ObjectSet target)
Reverses direction of lines in target object set using the coordinate system and the location precision of the
correct component.

ObjectSet Rotate(Component context, ObjectSet target, Number angle)
Rotates objects in target object set by specified amount of degrees using the coordinate system and the location
precision of the correct component.

ObjectSet Scale(Component context, ObjectSet target, Number scale)
Scales objects in target object set by specified factor using the coordinate system and the location precision of the
correct component.

ObjectSet ScaleHorizontally(Component context, ObjectSet target, Number scale)
Scales objects in target object set horizontally by specified factor using the coordinate system and the location
precision of the correct component.

ObjectSet ScaleVertically(Component context, ObjectSet target, Number scale)
Scales objects in target object set vertically by specified factor using the coordinate system and the location
precision of the correct component.

ObjectSet Segments(Component context, ObjectSet target, Number segments)
Splits straight line segments in objects in target object set into specified number of subsegments using the
coordinate system and the location precision of the correct component.

ObjectSet SelectAdjacentTo(Component context, ObjectSet target, ObjectSet source)
Selects objects in target object set adjacent to objects in source object set using the coordinate system and the
location precision of the correct component.

ObjectSet SelectContainedWithin(Component context, ObjectSet target, ObjectSet source)
Selects objects in target object set contained within objects in source object set using the coordinate system and the
location precision of the correct component.

ObjectSet SelectContaining(Component context, ObjectSet target, ObjectSet source)
Selects objects in target object set containing objects in source object set using the coordinate system and the
location precision of the correct component.

ObjectSet SelectCriticalServiceCenter(Component context, ObjectSet target, Number candidates)
Selects specified number of candidates for a critical service center for objects in target object set using the
coordinate system and the location precision of the correct component.

ObjectSet SelectEuclideanPointCoverage(Component context, ObjectSet target, Number threshold, String unit)

ObjectSet SelectEuclideanPointCoverage(Component context, ObjectSet target, Number threshold, Unit unit)
Selects minimum Euclidean point coverage with given distance threshold for objects in target object set using the
coordinate system and the location precision of the correct component. Unit parameter is optional and can be a Unit object or a unit name.

ObjectSet SelectIntersecting(Component context, ObjectSet target, ObjectSet source)
Selects objects in target object set intersecting objects in source object set using the coordinate system and the
location precision of the correct component.

ObjectSet SelectLineCoverage(Component context, ObjectSet target)
Selects minimum line coverage for objects in target object set using the coordinate system and the location
precision of the correct component.
ObjectSet SelectNCriticalServiceCenters(Component context, ObjectSet target, Number centers)
Selects locations for specified number of critical service centers for objects in target object set using the coordinate system and the location precision of the context component.

ObjectSet SelectNServiceCenters(Component context, ObjectSet target, Number centers)
Selects locations for specified number of regular service centers for objects in target object set using the coordinate system and the location precision of the context component.

ObjectSet SelectPointCoverage(Component context, ObjectSet target)
Selects minimum point coverage for objects in target object set using the coordinate system and the location precision of the context component.

ObjectSet SelectServiceCenter(Component context, ObjectSet target, Number candidates)
Selects specified number of candidates for a regular service center for objects in target object set using the coordinate system and the location precision of the context component.

ObjectSet SelectShortestPath(Component context, ObjectSet target, Object beg, Object end)
Selects shortest path between specified objects via objects in target object set using the coordinate system and the location precision of the context component.

ObjectSet SelectSpanningTree(Component context, ObjectSet target)
Selects minimum spanning tree for objects in target object set using the coordinate system and the location precision of the context component.

ObjectSet SelectTouching(Component context, ObjectSet target, ObjectSet source)
Selects objects in target object set touching objects in source object set using the coordinate system and the location precision of the context component.

ObjectSet ShapeHull(Component context, Drawing drawing, ObjectSet target, Number resolution)
Creates shape hull of specified resolution for all objects in target object set using the coordinate system and the location precision of the context component and places the new object into specified drawing.

ObjectSet SpanningTree(Component context, Drawing drawing, ObjectSet target)
Connects objects in target object set into minimum Euclidean spanning tree using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

AnalyzerValueSet SpanningTreeAssoc(Component context, ObjectSet target)
Connects objects in target object set into minimum Euclidean spanning tree using the coordinate system and the location precision of the context component and returns a set of resulting connections.

ObjectSet Spline(Component context, ObjectSet target, Number midpoints)
Smoothes lines and areas in target object set by converting each segment into a spline with the given number of midpoints. Uses the coordinate system and the location precision of the context component.

ObjectSet Split(Component context, Drawing drawing, ObjectSet target, ObjectSet source)
Splits objects in target object set with objects in source object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

ObjectSet Triangulation(Component context, Drawing drawing, ObjectSet target)
Creates triangulation of all objects in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

ObjectSet TriangulationAreas(Component context, Drawing drawing, ObjectSet target)
Creates triangulation areas of all objects in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing.
ObjectSet TriangulationLines(Component context, Drawing drawing, ObjectSet target)
Creates triangulation lines of all objects in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

ObjectSet Union(Component context, Drawing drawing, ObjectSet target)
Unions all areas in target object set using the coordinate system and the location precision of the context component and places the new object into specified drawing.

ObjectSet Voronoi(Component context, Drawing drawing, ObjectSet target)
Creates Voronoi diagram of all objects in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

ObjectSet VoronoiAreas(Component context, Drawing drawing, ObjectSet target)
Creates Voronoi areas of all objects in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

ObjectSet VoronoiLines(Component context, Drawing drawing, ObjectSet target)
Creates Voronoi lines of all objects in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

ObjectSet VoronoiPoints(Component context, Drawing drawing, ObjectSet target)
Creates Voronoi points of all objects in target object set using the coordinate system and the location precision of the context component and places the new objects into specified drawing.

Methods for Images and Surfaces

AddMargin(Image component, Number pixels)
AddMargin(Surface component, Number pixels)
Add margins of specified size to image or surface component.

AddNoise(PixelSet pixelSet, Number amount)
Add specified amount of noise to a set of image pixels.

AddNoiseMono(PixelSet pixelSet, Number amount)
Add specified amount of monochromatic noise to a set of image pixels.

AutoContrast(PixelSet pixelSet)
Autocontrasts a set of image pixels.

AutoLevels(PixelSet pixelSet)
Autolevels a set of image pixels.

Blur(PixelSet pixelSet, Number amount)
Filters a set of image or surface pixels with Blur. Amount parameter is optional.

Brightness(PixelSet pixelSet, Number amount)
Adjusts brightness of a set of image pixels by specified amount.

Contrast(PixelSet pixelSet, Number amount)
Adjusts contrast of a set of image pixels by specified amount.

CropMargin(Image component, Number pixels)
CropMargin(Surface component, Number pixels)
Crops margins of specified size from image or surface component.
Crop(PixelSet pixelSet)
Crops image or surface to given set of pixels.

Desaturate(PixelSet pixelSet)
Desaturates a set of image pixels.

DifferenceE(PixelSet pixelSet)
Filters a set of image or surface pixels with Difference East.

DifferenceN(PixelSet pixelSet)
Filters a set of image or surface pixels with Difference North.

DifferenceNE(PixelSet pixelSet)
Filters a set of image or surface pixels with Difference North East.

DifferenceNW(PixelSet pixelSet)
Filters a set of image or surface pixels with Difference North West.

DifferenceS(PixelSet pixelSet)
Filters a set of image or surface pixels with Difference South.

DifferenceSE(PixelSet pixelSet)
Filters a set of image or surface pixels with Difference South East.

DifferenceSW(PixelSet pixelSet)
Filters a set of image or surface pixels with Difference South West.

DifferenceW(PixelSet pixelSet)
Filters a set of image or surface pixels with Difference West.

Diffuse(PixelSet pixelSet, Number amount)
Diffuses colors in a set of image pixels by specified amount.

Equalize(PixelSet pixelSet, Number amount)
Equalizes colors in a set of image pixels by specified amount.

FlipPixelsHorizontally(PixelSet pixelSet)
Flips a set of image or surface pixels horizontally.

FlipPixelsVertically(PixelSet pixelSet)
Flips a set of image or surface pixels vertically.

Gamma(PixelSet pixelSet, Number amount)
Adjusts gamma of a set of image pixels by specified amount.

GaussianBlur(PixelSet pixelSet, Number radius)
Applies gaussian blur of specified radius to a set of image pixels.

Grayscale(PixelSet pixelSet)
Grayscale a set of image pixels.

HighPass1(PixelSet pixelSet)
Filters a set of image or surface pixels with High Pass 1.

HighPass2(PixelSet pixelSet)
Filters a set of image or surface pixels with High Pass 2.

HighPass3(PixelSet pixelSet)
Filters a set of image or surface pixels with High Pass 3.

Interpolate(PixelSet pixelSet, Number radius)
Interpolates invisible pixels in a set of surface pixels with given radius. Radius parameter is optional.

InterpolateRow(PixelSet pixelSet)
Interpolates invisible pixels in a set of surface pixels going by rows.

Invert(PixelSet pixelSet, Number level)
Inverts a set of image or surface pixels at specified level. Level parameter is optional.

Laplace1(PixelSet pixelSet)
Filters a set of image or surface pixels with Laplace 1.

Laplace2(PixelSet pixelSet)
Filters a set of image or surface pixels with Laplace 2.

LowPass1(PixelSet pixelSet)
Filters a set of image or surface pixels with Low Pass 1.

LowPass2(PixelSet pixelSet)
Filters a set of image or surface pixels with Low Pass 2.

LowPass3(PixelSet pixelSet)
Filters a set of image or surface pixels with Low Pass 3.

MedianCross(PixelSet pixelSet)
Filters a set of image or surface pixels with Median Cross.

MedianSquare(PixelSet pixelSet)
Filters a set of image or surface pixels with Median Square.

MedianSquare5(PixelSet pixelSet)
Filters a set of image or surface pixels with Median Square 5.

MotionBlurDiagonal1(PixelSet pixelSet, Number distance)
Applies (forward) diagonal motion blur of specified distance to a set of image pixels.

MotionBlurDiagonal2(PixelSet pixelSet, Number distance)
Applies (backward) diagonal motion blur of specified distance to a set of image pixels.

MotionBlurHorizontal(PixelSet pixelSet, Number distance)
Applies horizontal motion blur of specified distance to a set of image pixels.

MotionBlurVertical(PixelSet pixelSet, Number distance)
Applies vertical motion blur of specified distance to a set of image pixels.
Posterize(PixelSet pixelSet, Number levels)
Posterizes a set of image pixels to specified number of levels.

RotatePixels(Image component, Number angle)
RotatePixels(Surface component, Number angle)
Rotates image or surface to specified angle (in degrees).

Sharpen(PixelSet pixelSet, Number amount)
Filters a set of image or surface pixels with Sharpen. Amount parameter is optional.

SharpenMore(PixelSet pixelSet)
Filters a set of image or surface pixels with Sharpen More.

Threshold(PixelSet pixelSet, Number level)
Thresholds a set of image pixels at given level to black and white.

ThresholdBlack(PixelSet pixelSet, Number level)
Thresholds a set of image pixels at given level to black.

ThresholdLower(PixelSet pixelSet, Number level)
Thresholds pixels lower than given level in a set of surface pixels.

ThresholdUpper(PixelSet pixelSet, Number level)
Thresholds pixels higher than given level in a set of surface pixels.

ThresholdWhite(PixelSet pixelSet, Number level)
Thresholds a set of image pixels at given level to white.

Tile(PixelSet pixelSet, Number size)
Tiles a set of image or surface pixels choosing mean pixel values.

TileMedian(PixelSet pixelSet, Number size)
Tiles a set of image or surface pixels choosing median pixel values.

AnalyzerValue
AnalyzerValue Object
An association between a pair of objects.

Properties

Application Application
  Returns application. Read only.

Any Key
  Returns key object. Read only.

Any Parent
  Returns parent object. Read only.

Any Value
  Returns value object. Read only.

Obtained From

AnalyzerValueSet (Item)

See Also

Scripting Reference
AnalyzerValueSet Object
A set of associations between pairs of objects.

Properties

Application Application
   Returns application. Read only.

Number Count
   Returns number of associations in set. Read only.

AnalyzerValue Item(Number index)
   Returns association with given index. Read only.

Any Parent
   Returns parent object. Read only.

Methods

(none)

Obtained From

Analyzer (ClustersAssoc, ClustersZahnAssoc, DistanceNetworkAssoc, FarthestNeighorAssoc, FarthestNeighborSymmAssoc, FarthestPairAssoc, GabrielNetworkAssoc, NearestNeighborAssoc, NearestNeighborSymmAssoc, NearestPairAssoc, RelativeNeighborhoodNetworkAssoc, SpanningTreeAssoc)

**AnalyzerValueSetColumn Object**
A set of associations between pairs of objects.

**Properties**

Application Application
Returns application. Read only.

Number Count
Returns number of associations in set. Read only.

AnalyzerValueItem(Number index)
Returns association with given index. Read only.

Any Parent
Returns parent object. Read only.

**Methods**

SaveTo(Column column)
Saves values associated with objects to a given column. Column can be supplied directly or by its ID or name.

**Obtained From**

Analyzer (District, DistrictAdv, DistrictAdvGeom)

Scripting Reference
**Application Object**
Manages documents and application-wide properties.

**Properties**

Document ActiveDocument
- Returns active document. Read only.

Window ActiveWindow
- Returns active window. Read only.

Application Application
- Returns itself. Read only.

String Caption
- Sets or returns caption string. Read/write.

CoordinateSystemSet CoordinateSystemSet
- Returns available coordinate systems. Read only.

DatumSet DatumSet
- Returns available datums. Read only.

CoordinateSystem DefaultCoordinateSystem
- Returns default coordinate system for projected components. Read only.

CoordinateSystem DefaultCoordinateSystemLatLon
- Returns default coordinate system for latitude/longitude components. Read only.

Datum DefaultDatum
- Returns default datum. Read only.

Ellipsoid DefaultEllipsoid
- Returns default ellipsoid. Read only.

String DefaultFilePath
- Sets or returns default folder for mapfiles. Read/write.

Unit DefaultUnit
- Returns default unit for projected components. Read only.

Unit DefaultUnitLatLon
- Returns default unit for latitude/longitude components. Read only.

DocumentSet DocumentSet
- Returns set of open documents. Read only.

EllipsoidSet EllipsoidSet
- Returns available ellipsoids. Read only.

String FullName
- Returns fully qualified path to application executable. Read only.
Number Height
Sets or returns height of the main window in pixels. Read/write.

History History
Returns history object. Read only.

Boolean Interactive
Returns True if application is operating in interactive mode. Read only.

Number Left
Sets or returns left coordinate of the main window in pixels. Read/write.

String Name
Returns name of the application. Read only.

Any Parent
Returns itself. Read only.

String Path
Returns path to application executable. Read only.

RecentDataSourceSet RecentDataSourceSet
Returns a set of recently used data sources. Read only.

String StatusText
Sets or returns the contents of the status bar. Read/write.

String SerialNumberHash
Returns a hashed value for the serial number, for example, "BVh\...". Read only.

String SerialNumberHashHex
Returns a hashed value for the serial number in hexadecimal notation, for example, "121F\...". Read only.

Number Top
Sets or returns top coordinate of the main window in pixels. Read/write.

UnitSet UnitSet
Returns available units. Read only.

UserInterface UserInterface
Returns a user interface object that allows invoking commands and controlling elements of the user interface such as dialogs and controls. Read only.

Version Version
Returns version information. Read only.

Boolean Visible
Sets or returns visibility state of the main window (only works for scripts launched from the Manifold GUI). Read/write.

Number Width
Sets or returns width of the main window in pixels. Read/write.
WindowSet WindowSet
 Returns set of opened windows. Read only.

Methods

Help()
 Invokes help system.

String BytesToString(Object bytes)
 Converts an array of bytes into a string, automatically recognizing text encoding.

String InputBox(String prompt, String caption, String initialValue)
 Displays the input box with specified prompt and caption and waits for user input. Initial value is optional.

MessageBoxResult MessageBox(String message, String caption)
 Displays message box with specified text and optional caption.

MessageBoxResult MessageBoxEx(String message, String caption, MessageBoxType type)
 Displays message box with specified text, caption, icons and buttons. Returns the identifier of the pressed button.

BranchSet NewBranchSet()
 Creates new branch set.

Color NewColor(String name, Number red, Number green, Number blue, Number alpha)
 Creates new color with given name and RGBA components. All parameters are optional.

ColumnLookupSet NewColumnLookupSet()
 Creates new column lookup set.

ColumnSet NewColumnSet()
 Creates new set of columns.

ControlPoint NewControlPoint(String name, Number x, Number y)
 Creates new control point with given name and location.

ConverterProperty NewConverterProperty(String name, String value)
 Creates new converter property for given name and value.

CoordinateConverter NewCoordinateConverter()
 Creates new coordinate converter.

CoordinateSystem NewCoordinateSystem(String preset)
 Creates new coordinate system using name of coordinate system preset.

CoordinateSystem NewCoordinateSystemFrom(String xml)
 Creates new coordinate system from given XML string.

CoordinateSystem NewCoordinateSystemFromBinary(Object binary)
 Creates new coordinate system from binary data.

CoordinateSystem NewCoordinateSystemFromEpsg(String epsg)
Manifold® System Release 8.00 User Manual

Creates new coordinate system from given EPSG code.

CoordinateSystem NewCoordinateSystemFromFile(String path)
Creates new coordinate system from given XML file.

CoordinateSystem NewCoordinateSystemFromFileAUX(String path)
Creates new coordinate system from given ERDAS AUX file.

CoordinateSystem NewCoordinateSystemFromTextGSR(String text, Number width, Number height)
Creates new coordinate system from given GSR string. The last two parameters are the width and height of an image or surface which has the coordinate system, and are optional.

CoordinateSystem NewCoordinateSystemFromTextPRJ(String text)
Creates new coordinate system from given PRJ string.

CoordinateSystem NewCoordinateSystemFromTextWKT(String text)
Creates new coordinate system from given WKT string (same as PRJ string).

DataSourceColumnSet NewDataSourceColumnSet()
Creates new column set for specifying export or import columns.

Datum NewDatum(String name)
Creates new datum using datum name.

Document NewDocument(String name, Boolean readOnly)
Creates new document or opens document from given file.

Ellipsoid NewEllipsoid(String name)
Creates new ellipsoid using ellipsoid name.

Export NewExport(String name)
Creates new exporter using exporter name.

Geocoder NewGeocoder()
Creates new geocoder object.

Geom NewGeom(GeomType type)
Creates new geometric entity of given type.

Geom NewGeom(GeomType type, BranchSet branchSet)
Creates new geometric entity of given type and branches.

Geom NewGeom(GeomType type, Branch branch)
Creates new geometric entity of given type and single branch.

Geom NewGeom(GeomType type, PointSet pointSet)
Creates new geometric entity of given type and single branch.

Geom NewGeomFromBinary(Object binary)
Creates new geometric entity from binary data in Geometry format.

Geom NewGeomFromBinarySDE(Object binary, Number shiftX, Number shiftY, Number scale)
Creates new geometric entity from binary data in Geometry (SDE) format. Shift and scale parameters specify conversion factors from integer coordinates and are optional. If omitted, shiftX is set to 0, shiftY is set to 0, and scale is set to 1.

`Geom NewGeomFromBinarySHP(Object binary)`
Creates new geometric entity from binary data in Geometry (SHP) format.

`Geom NewGeomFromBinaryWKB(Object binary)`
Creates new geometric entity from binary data in Geometry (WKB) format.

`Geom NewGeomFromTextWKT(String text)`
Creates new geometric entity from textual data in OGC WKT format.

`Import NewImport(String name)`
Creates new importer using importer name.

`Point NewPoint(Number x, Number y)`
Creates new point with given coordinates. Both parameters are optional.

`Point NewPointFromUSNG(String usng)`
Creates a new point from USNG coordinate string.

`PointSet NewPointSet()`
Creates new set of points.

`Progress NewProgress()`
Creates new progress indicator.

`Rect NewRect(Number minX, Number minY, Number maxX, Number maxY)`
Creates new rectangle object with specified coordinates. All parameters are optional.

`Topology NewTopology()`
Creates new topology object.

`Unit NewUnit(String name)`
Creates new unit using unit name.

`View NewView(String name, Number scale, Number x, Number y)`
Creates new view with given name, scale and location.

`Quit()`
Quits application; prompts to save changes.

`Repeat()`
Repeats last undone action.

`Undo()`
Undoes last action.

**Obtained From**

No need to create (accessed through global Application object).
See Also

Scripting Reference
Branch Object
A sequence of points representing part of geometric object.

Properties

Application Application
  Returns application. Read only.

Number Area
  Returns area measured over an ellipsoid. Returned value is in square meters. Read only.

Number AreaNative
  Returns area in native units. Read only.

Rect Box
  Sets or returns bounding box. Modifying this property scales and shifts the branch. Read/write.

Point Center
  Sets or returns center of minimum enclosing circle. Modifying this property moves the branch. Read/write.

Number Length
  Returns length or perimeter measured over an ellipsoid. Returned value is in meters. Read only.

Number LengthNative
  Returns length or perimeter in native units. Read only.

Any Parent
  Returns parent object. Read only.

PointSet PointSet
  Sets or returns set of points (can accept Branch or PointSet when setting). Read/write.

Number SequentialNumber
  Returns sequential number of the branch in its parent. Read only.

Number Start
  Returns sequential number of the first point of the branch in its parent. Read only.

Methods

Copy(Branch branch)
  Copies given branch.

Boolean IsEmpty()
  Returns True if branch contains no points and False otherwise.

Boolean IsFirst()
  Returns True if branch is the first branch in its parent and False otherwise.

Boolean IsLast()
  Returns True if branch is the last branch in its parent and False otherwise.
Obtained From

BranchSet (Item, LastAdded)

See Also

Scripting Reference
BranchSet Object
Set of branches representing geometric object.

Properties

Application Application
Returns application. Read only.

Rect Box
Sets or returns bounding box. Modifying this property scales and shifts the branch set. Read/write.

Point Center
Sets or returns center of minimum enclosing circle. Modifying this property moves the branch set. Read/write.

Number Count
Returns number of branches in set. Read only.

Branch Item(Number index)
Sets or returns branch with given index (can accept Branch or PointSet when setting). Read/write.

Branch LastAdded
Returns last added branch if any. Read only.

Any Parent
Returns parent object. Read only.

Methods

Add(Branch branch)
Appends branch to branch set.

Add(PointSet pointSet)
Creates new branch from given point set and appends it to branch set.

Copy(BranchSet branchSet)
Copies given branch set.

Remove(Number index)
Removes branch with given index from branch set.

RemoveAll()
Removes all branches.

Obtained From

Application (NewBranchSet)
Geom (BranchSet)
Label (BranchSet)
Object (BranchSet)

See Also
Chart Object
Chart component.

Properties

Application Application
Returns application. Read only.

String Description
Sets or returns component description. Read/write.

Document Document
Returns owner document. Read only.

Folder Folder
Sets or returns containing folder. Read/write.

ColumnSet Groups
Returns set of columns used for grouping. Read only.

Number ID
Returns unique component ID. Read only.

Boolean LogarithmicScale
Sets or returns logarithmic scale option. Read/write.

String Name
Sets or returns component name. Read/write.

String Note
Sets or returns notes associated with the component. Read/write.

ComponentSet OwnedComponentSet
Returns set of components bound to this component. Read only.

ComponentSet OwnedLayoutSet
Returns set of layouts bound to this component. Read only.

Component Owner
Returns owner component if any. Read only.

Any Parent
Returns parent object. Read only.

Border PrintBorder
Sets or returns border used for printing. Read/write.

Boolean PrintLegend
Sets or returns legend printing option. Read/write.

ColumnSet Series
Returns set of displayed columns. Read only.
ComponentType Type
Returns component type. Read only.

String TypeName
Returns textual representation of the component type. Read only.

Methods

Copy()
Copies component into the Clipboard.

Open()
Opens component.

OpenInNewWindow()
Opens component in new window.

Print(Boolean useDialog)
Prints component.

RenderTo(String name, Number width, Number height)
Render component into an image with given name, width and height.

Obtained From

Document (NewChart)

Scripting Reference
Color Object  
Color value.

Properties

Number Alpha
Returns value of the alpha channel from 0 to 255. 0 means that the color is completely opaque and 255 means that the color is completely transparent. Read only.

Application Application
Returns application. Read only.

Number Blue
Returns intensity of the blue channel from 0 to 255. Read only.

Number Green
Returns intensity of the green channel from 0 to 255. Read only.

Number Hue
Returns value of the hue from 0 to 255. Read only.

Number Intensity
Returns absolute value of the intensity from 0 to 255. Read only.

Number Lightness
Returns value of the lightness from 0 to 255. Read only.

String Name
Returns color name. Read only.

Any Parent
Returns parent object. Read only.

Number Red
Returns intensity of the red channel from 0 to 255. Read only.

Number Saturation
Returns value of the saturation from 0 to 255. Read only.

Methods

Color Darker()
Creates a darker version of the color.

Color Lighter()
Creates a lighter version of the color.

Scripting Reference
**Column Object**  
Table column.

**Properties**

**Application Application**  
Returns application. Read only.

**Boolean AutoRefresh**  
Sets or returns autorefresh flag of the active column. Read/write.

**ColumnCategory Category**  
Returns column category. Read only.

**Number CodePage**  
Sets or returns the code page of an ANSI text column. Read/write.

**ComputationMode ComputationMode**  
Sets or returns column computation mode (active columns only). Read/write.

**Variant DefaultValue**  
Sets or returns default value. Read/write.

**String DefaultValueText**  
Returns default value in textual form. Read only.

**DSSQuery DSSQuery**  
Returns DSS query of the rank column. Read only.

**ColumnFormat Format**  
Returns column formatting options. Read only.

**String Function**  
Sets or returns function name of the active column. Read/write.

**Number ID**  
Returns unique column ID. Read only.

**Boolean Identity**  
Sets or returns identity flag. Read/write.

**ColumnLookupSet LookupValues**  
Returns values of the lookup column. Read only.

**String Name**  
Sets or returns column name. Read/write.

**Boolean Nullable**  
Sets or returns nullable flag of the linked column. Read/write.

**Column OriginColumn**  
Sets or returns origin column of the mapped column. Read/write.
Component Owner
Returns table component containing this column if any. Read only.

Any Parent
Returns parent object. Read only.

Boolean PrimaryKey
Sets or returns primary key flag of the linked column. Read/write.

Number Size
Sets or returns column size. Read/write.

Table Table
Returns containing table if any. Read only.

TransferRuleDiv TransferDiv
Sets or returns 1 to N transfer rule.

Column TransferDivColumn
Sets or returns a column used with "proportional" 1 to N transfer rule.

TransferRuleMul TransferMul
Sets or returns N to 1 transfer rule.

ColumnType Type
Sets or returns column type. Read/write.

String TypeName
Returns name of the column type. Read only.

Boolean Unique
Sets or returns unique flag of the linked column. Read/write.

**Methods**

Flatten()
Converts active column, rank column or column brought by relation to native column.

Boolean IsActive()
Returns True for active columns and False for other columns.

Boolean IsForeign()
Returns True for columns mapped from another table and False for other columns.

Boolean IsIntrinsic()
Returns True for intrinsic columns and False for other columns.

Boolean IsKey()
Returns True for linked columns that are primary keys and False for other columns.

Boolean IsLinked()
Returns True for linked columns and False for other columns.
Boolean IsLookup()
    Returns True for lookup columns and False for other columns.

Boolean IsNative()
    Returns True for native columns and False for other columns.

Boolean IsQuery()
    Returns True for columns created by the query and False for other columns.

Boolean IsRank()
    Returns True for rank columns and False for other columns.

Boolean IsTypeBinary()
    Returns True for binary columns and False for other columns.

Boolean IsTypeBoolean()
    Returns True for boolean columns and False for other columns.

Boolean IsTypeCoordSys()
    Returns True for coordinate system columns and False for other columns.

Boolean IsTypeCurrency()
    Returns True for currency columns and False for other columns.

Boolean IsTypeGeometry()
    Returns True for geometry columns and False for other columns.

Boolean IsTypeLatitude()
    Returns True for latitude columns and False for other columns.

Boolean IsTypeLongitude()
    Returns True for longitude columns and False for other columns.

Boolean IsTypeNumeric()
    Returns True for numeric columns and False for other columns.

Boolean IsTypePercent()
    Returns True for percentage columns and False for other columns.

Boolean IsTypeString()
    Returns True for text columns and False for other columns.

Boolean IsTypeSymbol()
    Returns True for character columns and False for other columns.

Boolean IsTypeTime()
    Returns True for date and time columns and False for other columns.

Boolean IsTypeUnsigned()
    Returns True for unsigned columns and False for other columns.

Boolean IsTypeUrl()
Returns True for URL columns and False for other columns.

Boolean IsTypeValid()
Returns True if column type is valid and False otherwise.

Boolean IsTypeVector()
Returns True for vector columns and False otherwise.

Paste()
Pastes the contents of the Clipboard into the column.

Recompute()
Recomputes active column.

Obtained From

**ColumnFormat Object**
Formatting options for table column.

**Properties**

ColumnAlign Align
Sets or returns column alignment. Read/write.

Application Application
Returns application. Read only.

Number Decimals
Sets or returns number of decimal digits. Read/write.

Number Indent
Sets or returns indentation in pixels. Read/write.

ColumnFormatNeg NegativeStyle
Sets or returns formatting options for negative values. Read/write.

Any Parent
Returns parent object. Read only.

ColumnFormatPos PositiveStyle
Sets or returns formatting options for positive values. Read/write.

String Style
Sets or returns format style. Read/write.

Boolean Thousands
Sets or returns thousand formatting option. Read/write.

Number Width
Sets or returns column width in pixels. Read/write.

**Obtained From**

Column (Format)

Scripting Reference
**ColumnLookupSet Object**
Set of values for lookup columns.

**Properties**

Applycation Application
Returns application. Read only.

Number Count
Returns number of lookup values in set. Read only.

LookupValue Item(Number index)
Returns lookup value with given index. Read only.

LookupValue LastAdded
Returns last added lookup value. Read only.

Any Parent
Returns parent object. Read only.

**Methods**

Add(LookupValue value)
Appends lookup value to lookup set.

Number ItemByCaption(String caption)
Returns index of value with given caption or -1.

LookupValue NewLookupValue()
Returns lookup value that can later be added to lookup set.

Remove(Number item)
Removes lookup value with given index from lookup set.

**Obtained From**

Application (NewColumnLookupSet)
Column (LookupValues)

Set of table columns.

**Properties**

Application Application
Returns application. Read only.

Number Count
Returns number of columns in set. Read only.

Column Item(Number index)
Column Item(String name)
Returns column with given index or name. Read only.

Column LastAdded
Returns last added column if any. Read only.

Component OwnerComponent
Returns table component containing this set of columns if any. Read only.

Any Parent
Returns parent object. Read only.

**Methods**

Add(Column column)
Appends column to column set.

Number ItemByID(Number id)
Returns index of column with given ID or -1.

Number ItemByName(String name)
Returns index of column with given name or -1.

Column NewColumn()
Creates new column that can later be added into column set.

Remove(Number index)
Removes column with given index from column set.

RemoveAll()
Removes all columns.

Comments Object
Comments component.

Properties

Application Application
Returns application. Read only.

Boolean Cached
Sets or returns caching option for shared component in Enterprise Edition. Read/write.

String Description
Sets or returns component description. Read/write.

Document Document
Returns owner document. Read only.

Folder Folder
Sets or returns containing folder. Read/write.

Number ID
Returns unique component ID. Read only.

Boolean IsCheckedOut
Checks if component is shared and checked out in Enterprise Edition. Read only.

Boolean IsCheckedOutRemotely
Checks if component is shared and checked out by another user in Enterprise Edition. Read only.

Boolean IsModified
Checks if component is modified since last save in Enterprise Edition. Read only.

Boolean IsOutdated
Checks if component is shared and there is a later version of the component on the Enterprise server in Enterprise Edition. Read only.

Boolean IsReadOnly
Checks if component is readonly (eg, shared and not checked out) in Enterprise Edition. Read only.

Boolean IsShared
Checks if component is shared on an Enterprise server in Enterprise Edition. Read only.

Boolean IsWritable
Checks if component is writable in Enterprise Edition. Read only.

Number Length
Returns number of characters in comments text. Read only.

String Name
Sets or returns component name. Read/write.

String Note
Sets or returns notes associated with the component. Read/write.
ComponentSet OwnedComponentSet
Returns set of components bound to this component. Read only.

ComponentSet OwnedLayoutSet
Returns set of layouts bound to this component. Read only.

Component Owner
Returns owner component if any. Read only.

Any Parent
Returns parent object. Read only.

Number RemoteVersion
Returns version of shared component available on the Enterprise server in Enterprise Edition. Read only.

String Server
Returns server identification string for shared component in Enterprise Edition. Read only.

String ShareStatus
Returns textual report on component sharing status in Enterprise Edition. Read only.

String Text
Sets or returns comments text. Read/write.

ComponentType Type
Returns component type. Read only.

String TypeName
Returns textual representation of the component type. Read only.

Number Version
Returns version of shared component within the local project in Enterprise Edition. Read only.

Methods

AddText(String text)
Appends text to the end of the component.

CheckIn()
Checks in changes made to a shared component to the Enterprise server in Enterprise Edition.

CheckOut()
Checks out a shared component for editing in Enterprise Edition.

Clear()
Clears component.

Copy()
Copies component into the Clipboard.

Cut()
Copies component into the Clipboard and then clears it.
GetLatestVersion()
Gets the latest version of a shared component from the Enterprise server in Enterprise Edition.

Boolean IsEmpty(Boolean ignoreWhiteSpaces)
Returns True if component text is empty and False otherwise.

Open()
Opens component.

OpenInNewWindow()
Opens component in new window.

Paste(Boolean replace)
Pastes the contents of the Clipboard into the component replacing previous data or adding to it. Calling the method without parameters replaces data.

Print(Boolean useDialog)
Prints component.

UndoCheckOut()
Undoes changes made to a shared component and gets the latest version of the component from the Enterprise server in Enterprise Edition.

Returns property with given index. Read only.

ConverterProperty LastAdded
Returns last added property if any. Read only.

Any Parent
Returns parent object. Read only.

Methods

Add(ConverterProperty property)
Appends property to property set.

Remove(Number index)
Removes property with given index from property set.

Remove(String name)
Removes property with given name from property set.

RemoveAll()
Removes all properties from property set.

Obtained From

Export (PropertySet)
Import (PropertySet)

Scripting Reference
**CoordinateConverter Object**
Coordinate system converter.

**Methods**

Convert(Branch branch, Variant status)
Converts set of points in a branch and writes conversion status for each point.

Convert(BranchSet branchSet, Variant status)
Converts set of points in a set of branches and writes conversion status for each point.

Convert(Geom geom, Variant status)
Converts geometric entity and writes conversion status for each point.

Convert(GeomSet geomSet, Variant status)
Converts set of geometric entities and writes conversion status for each point.

Convert(Point pointSet, Variant status)
Converts point and writes conversion status.

Convert(PointSet pointSet, Variant status)
Converts set of points and writes conversion status for each point.

Boolean ConvertsData()
Returns True if source and target coordinate systems are not the same and False otherwise.

Prepare(CoordinateSystem source, CoordinateSystem target)
Prepares coordinate converter with source and target coordinate systems.

**Obtained From**

Application (NewCoordinateConverter)

**See Also**

Scripting Reference
CoordinateSystem Object
Coordinate system.

For conversions between two different coordinate systems use CoordinateConverter Object.

Properties

Application Application
Returns application. Read only.

String Category
Returns coordinate system category. Read only.

Datum Datum
Sets or returns datum. Read/write.

String Name
Returns coordinate system name. Read only.

CoordinateSystemParameterSet ParameterSet
Returns set of coordinate system parameters. Read only

Any Parent
Returns parent object. Read only.

String Preset
Returns preset used to create coordinate system. Read only.

Unit Unit
Sets or returns unit. Read/write.

Methods

Point ConvertForward(Point point)
Converts point from latitude/longitude to coordinate system.

Point ConvertInverse(Point point)
Converts point from coordinate system to latitude/longitude.

Copy(CoordinateSystem coordinateSystem)
Copies given coordinate system.

Boolean Edit()
Edits coordinate system in a dialog. Returns True if editing has been accepted and False otherwise.

Boolean IsEqualTo(CoordinateSystem system, Boolean compareShiftsScales, Boolean compareDatums)
Compares coordinate system to another coordinate system. Returns True if coordinate systems are equal to each other and False otherwise. Two last parameters are optional (both are True by default).

Boolean IsLatLon()
Returns True if coordinate system transforms locations to latitude/longitude and False otherwise.

Load(String name)
Loads coordinate system using given name.

LoadFrom(String xml)
Loads coordinate system from given XML string.

LoadFromBinary(Object binary)
 Loads coordinate system from given binary data.

LoadFromFile(String path)
Loads coordinate system from given XML file.

Object ToBinary()
Creates a binary representation of a coordinate system.

SaveToFile(String path)
Saves coordinate system to given XML file.

String ToTextGSR(Number width, Number height)
Saves coordinate system to GSR string. The last two parameters are the width and height of an image or surface which has the coordinate system, and are optional.

String ToTextPRJ()
Saves coordinate system to PRJ string.

String ToTextWKT()
Saves coordinate system to WKT string (same as PRJ string).

String ToXML()
Saves coordinate system to XML string.

Scripting Reference
CoordinateSystemParameter Object
Coordinate system parameter. Parameters with maximum value lower than minimum value can have any numeric value. Parameters with maximum value higher than minimum value can have values between those two.

Properties

**Application**
Returns application. Read only.

**Number MaxValue**
Returns maximum possible value. Read only.

**Number MinValue**
Returns minimum possible value. Read only.

**String Name**
Returns parameter name. Read only.

**Any Parent**
Returns parent object. Read only.

**CoordinateSystemParameterType Type**
Returns parameter type. Read only.

**String TypeName**
Returns textual representation of parameter type. Read only.

**Number Value**
Sets or returns parameter value. Read/write.

**Obtained From**

CoordinateSystemParameterSet (Item)

**See Also**

Scripting Reference
CoordinateSystemParameterSet Object
Set of coordinate system parameters.

Properties

Application Application
Returns application. Read only.

Number Count
Returns number of parameters in set. Read only.

CoordinateSystemParameter Item(Number index)
CoordinateSystemParameter Item(String name)
Returns parameter with given index or name. Read only.

Any Parent
Returns parent object. Read only.

Methods

Number ItemByName(String name)
Returns index of parameter with given name or -1.

Obtained From

CoordinateSystem (Parameters)

Scripting Reference
**DataSource Object**

A data source.

**Properties**

- **Application**
  - **Application**
    - Returns application. Read only.

- **ConnectionString**
  - **String**
    - Sets or returns connection string. Read/write.

- **ConnectionType**
  - **String**

- **Parent**
  - **Any**
    - Returns parent object. Read only.

**Methods**

- **ExportDrawing(Drawing drawing, String name, String type, Number srid, Boolean createIndex, Boolean createSequenceTriggers, DataSourceColumnSet columns)**
  - Exports a drawing using the specified name and drawing type. If the SRID parameter is set to -1, the system uses the coordinate system that best matches the coordinate system of the exported component. All parameters except the first three are optional.

- **ExportImage(Image image, String name, String type, Number srid, Boolean createPyramids, String compression)**
  - Exports an image using the specified name and image type. If the SRID parameter is set to -1, the system uses the coordinate system that best matches the coordinate system of the exported component. All parameters except the first three are optional.

- **ExportSurface(Surface surface, String name, String type, Number srid, Boolean createPyramids, String compression)**
  - Exports a surface using the specified name and surface type. If the SRID parameter is set to -1, the system uses the coordinate system that best matches the coordinate system of the exported component. All parameters except the first three are optional.

- **ExportTable(Table table, String name, DataSourceColumnSet columns)**
  - Exports a table using the specified name. The last parameter is optional.

- **ImportDrawing(String drawing, DataSourceColumnSet columns)**
  - Imports a native or Manifold drawing with specified name. The last parameter is optional.

- **ImportDrawingFromTableCoordinates(String table, String columnX, String columnY, Boolean latLon, String columnLineID, String columnCoordinateOrder, DataSourceColumnSet columns)**
  - Imports a drawing from a table with coordinate columns. All parameters except the first three are optional.

- **ImportDrawingFromTableGeometry(String table, String columnGeometry, ColumnType geometryType, String columnVersion, DataSourceColumnSet columns)**
  - Imports a drawing from a table with a geometry column. All parameters except the first three are optional.

- **ImportImage(String image)**
  - Imports a native or Manifold image with specified name.
ImportImageFromTableChannels(String table, Number channels, String columnX, String columnY, String columnRed, String columnGreen, String columnBlue, String columnAlpha)
Imports an image from a table with channel columns. The number of channels can be 1, 3 or 4. All parameters except the first five are optional.

ImportImageFromTableColor(String table, Number channels, String columnX, String columnY, String columnColor)
Imports an image from a table with a color column. The number of channels can be 1, 3 or 4.

ImportSurfaceFromImageChannel(String image, Number channel)
Imports a surface from a channel of a native or Manifold image with specified name. If the channel index is set to -1, imports the heights channel. The channel index parameter is optional.

ImportSurfaceFromTableValue(String table, ColumnType resultType, String columnX, String columnY, String columnValue)
Imports a surface from a table with a value column.

ImportTable(String table, DataSourceColumnSet columns)
Imports a table with specified name. The last parameter is optional.

LinkDrawing(String drawing, DataSourceColumnSet columns)
Links a native or Manifold drawing with specified name. The last parameter is optional.

LinkDrawingFromTableCoordinates(String table, String columnX, String columnY, Boolean latLon, String columnLineID, String columnCoordinateOrder, DataSourceColumnSet columns)
Links a drawing from a table with coordinate columns. All parameters except the first three are optional.

LinkDrawingFromTableGeometry(String table, String columnGeometry, ColumnType geometryType, String columnVersion, DataSourceColumnSet columns)
Links a drawing from a table with a geometry column. All parameters except the first three are optional.

LinkImage(String image)
Links a native or Manifold image with specified name.

LinkImageFromTableChannels(String table, Number channels, String columnX, String columnY, String columnRed, String columnGreen, String columnBlue, String columnAlpha)
Links an image from a table with channel columns. The number of channels can be 1, 3 or 4. All parameters except the first five are optional.

LinkImageFromTableColor(String table, Number channels, String columnX, String columnY, String columnColor)
Links an image from a table with a color column. The number of channels can be 1, 3 or 4.

LinkSurfaceFromTableValue(String table, ColumnType resultType, String columnX, String columnY, String columnValue)
Links a surface from a table with a value column.

LinkTable(String table, DataSourceColumnSet columns)
Links a table with specified name. The last parameter is optional.

Boolean Probe()
Tries to connect to the data source. Returns True if the data source can be reached, and False otherwise.

**DataSourceColumnSet Object**

A set of column names to export or import.

**Properties**

**Application Application**

Returns application. Read only.

**Number Count**

Returns number of column names in set. Read only.

**String Item(Number index)**

Returns column name with given index. Read only.

**String LastAdded**

Returns last added column name. Read only.

**Any Parent**

Returns parent object. Read only.

**Methods**

**Add(String column)**

Adds a column name to a set.

**Remove(Number index)**

Removes a column name with given index.

**RemoveAll()**

Removes all column names.

**Obtained From**

Application (NewDataSourceColumnSet)

**See Also**

Scripting Reference
Datum Object
Datum.

Properties

Application Application
Returns application. Read only.

Ellipsoid Ellipsoid
Returns reference ellipsoid. Read/write

String Name
Returns datum name. Read only.

Any Parent
Returns parent object. Read only.

Number ScaleAdjustment
Sets or returns scale adjustment, in units per million. Read/write.

Number XRotation
Sets or returns rotation along the X axis, in degrees. Read/write.

Number XShift
Sets or returns offset along the X axis, in meters. Read/write.

Number YRotation
Sets or returns offset along the Y axis, in meters. Read/write.

Number YShift
Returns center shift by Y axis. Read/write.

Number ZRotation
Sets or returns rotation along the Z axis, in degrees. Read/write.

Number ZShift
Sets or returns offset along the Z axis, in meters. Read/write.

Methods

Load(String name)
Loads datum using given name.

 Obtained From

 Application (NewDatum, DefaultDatum)
 CoordinateSystem (Datum)
 DatumSet (Item)

Scripting Reference
**DatumSet Object**
Set of datums.

**Properties**

- **Application Application**
  Returns application. Read only.

- **Number Count**
  Returns number of datums in set. Read only.

- **Datum Item(Number index)**
- **Datum Item(String name)**
  Returns datum with given index or name. Read only.

- **Any Parent**
  Returns parent object. Read only.

**Methods**

- **Number ItemByName(String name)**
  Returns index of datum with given name or -1.

**Obtained From**

- **Application (DatumSet)**

**See Also**

- **Scripting Reference**
**Document Object**  
Manages components and document-wide properties.

**Properties**

**Boolean Active**  
Returns True if the document is the active document displayed by the Manifold user interface, and False otherwise. Read only.

**Application Application**  
Returns application. Read only.

**String Author**  
Sets or returns document author. Read/write.

**Boolean BatchUpdates**  
Sets or returns batch update mode. When batch mode is on, changes made by script are not immediately propagated to the mapfile, which is faster but can make script objects report outdated information. The recommended technique is to turn BatchUpdates on when changing large bulks of data and turn it back off when all necessary changes have been done. Read/write.

**String Comments**  
Sets or returns comments associated with document. Read/write.

**ComponentSet ComponentSet**  
Returns set of document components. Read only.

**String FullName**  
Returns fully qualified filename of a document. Returns empty string for newly created documents. Read only.

**String Keywords**  
Sets or returns list of keywords associated with document. Read/write.

**String Name**  
Returns document name. Read only.

**Any Parent**  
Returns parent object. Read only.

**String Path**  
Returns path to the document file. Read only.

**Boolean ReadOnly**  
Returns True if document is opened in read only mode and False otherwise. Read only.

**Boolean Saved**  
Returns True if document has been saved after the latest modifications and False otherwise. Read only.

**String Subject**  
Sets or returns subject associated with document. Read/write.

**String Title**  
Sets or returns document title. Read/write.
Methods

CheckIn(ComponentSet components)
Checks in changes made to shared components to the Enterprise server or servers in Enterprise Edition.

CheckInAll()
Checks in changes made to all shared components in the document to the Enterprise server or servers in Enterprise Edition.

CheckOut(ComponentSet components)
Checks out shared components for editing in Enterprise Edition.

CheckOutAll()
Checks out all shared components in the document for editing in Enterprise Edition.

Close(Boolean saveChanges)
Closes document saving or discarding changes. If argument is omitted, the changes are saved. If document contains running script the method fails.

Clear()
Removes all components excluding running script component and any components it depends on (tables, drawings, folders).

GetLatestVersion(ComponentSet components)
Gets the latest version of shared components from the Enterprise server or servers in Enterprise Edition.

GetLatestVersionAll()
Gets the latest version of all shared components in the document from the Enterprise server or servers in Enterprise Edition.

Analyzer NewAnalyzer()
Creates new analyzer object.

Chart NewChart(String name, Table table, Boolean exactName)
Creates new chart component for given table. Exact name parameter is optional. When it is set to False or omitted, the system adjusts the name so that there are no collisions with existing components.

Comments NewComments(String name, Boolean exactName)
Creates new comments component. Exact name parameter is optional. When it is set to False or omitted, the system adjusts the name so that there are no collisions with existing components.

ComponentSet NewComponentSet()
Creates new component set object for later use in NewMap and similar methods.

DataSource NewDataSource()
Creates a new data source for exporting or importing data.

Drawing NewDrawing(String name, CoordinateSystem system, Boolean exactName)
Creates new drawing component. Coordinate system and exact name parameters are optional. When exact name is set to False or omitted, the system adjusts the name so that there are no collisions with existing components.

Elevation NewElevation(String name, Profile profile, Boolean exactName)
Creates new elevation component for given profile. Exact name parameter is optional. When it is set to False or omitted, the system adjusts the name so that there are no collisions with existing components.

Export NewExport(String name)
Creates new exporter using exporter name.

Folder NewFolder(String name, Boolean exactName)
Creates new folder component. Exact name parameter is optional. When it is set to False or omitted, the system adjusts the name so that there are no collisions with existing components.

Form NewForm(String name, Boolean exactName)
Creates new form component. Exact name parameter is optional. When it is set to False or omitted, the system adjusts the name so that there are no collisions with existing components.

Image NewImage(String name, Number width, Number height, ImageType type, CoordinateSystem system, Boolean exactName)
Creates new image component. Width, height, type, coordinate system and exact name parameters are optional. When exact name is set to False or omitted, the system adjusts the name so that there are no collisions with existing components.

Import NewImport(String name)
Creates new importer using importer name.

Labels NewLabels(String name, CoordinateSystem system, Boolean exactName)
Creates new labels component. Coordinate system and exact name parameters are optional. When exact name is set to False or omitted, the system adjusts the name so that there are no collisions with existing components.

Labels NewLabels(String name, Drawing drawing, Boolean exactName, Boolean populate)
Creates new labels component linked to given drawing. The last two parameters are optional. When the exact name parameter is set to False or omitted, the system adjusts the name so that there are no collisions with existing components. When the populate parameter is set to True, the system automatically populates the labels component with a label for each drawing object.

Layer NewLayer(Component component, Number opacity)
Creates new layer with given component. Opacity parameter is optional and can vary from 100 (opaque) to 0 (transparent).

Layout NewLayout(String name, Component component, Boolean exactName, String template)
Creates new layout component. Component, exact name and template parameters are optional. When exact name is set to False or omitted, the system adjusts the name so that there are no collisions with existing components.

Map NewMap(String name, Component layer, CoordinateSystem system, Boolean exactName)
Map NewMap(String name, ComponentSet layers, CoordinateSystem system, Boolean exactName)
Creates new map component. Coordinate system and exact name parameters are optional.

ObjectSet NewObjectSet(Object content)
ObjectSet NewObjectSet(ObjectSet content)
Creates new static object set with given content. Content parameter is optional.

Palette NewPalette(String name, Boolean exactName)
Creates new palette component. Exact name parameter is optional. When it is set to False or omitted, the system adjusts the name so that there are no collisions with existing components.

Profile NewProfile(String name, Surface surface, Branch metric, Boolean exactName)
Profile NewProfile(String name, Surface surface, BranchSet metric, Boolean exactName)
Profile NewProfile(String name, Surface surface, Geom metric, Boolean exactName)
Profile NewProfile(String name, Surface surface, PointSet metric, Boolean exactName)

Creates new profile component for given surface. Metric parameter is optional. Exact name parameter is optional. When it is set to False or omitted, the system adjusts the name so that there are no collisions with existing components.

Query NewQuery(String name, Boolean exactName)

Creates new query component. Exact name parameter is optional. When it is set to False or omitted, the system adjusts the name so that there are no collisions with existing components.

Script NewScript(String name, Boolean exactName)

Creates new script component. Exact name parameter is optional. When it is set to False or omitted, the system adjusts the name so that there are no collisions with existing components.

Surface NewSurface(String name, Number width, Number height, ValueType type, CoordinateSystem system, Boolean exactName)

Creates new surface component. Width, height, type, coordinate system and exact name parameters are optional. When exact name is set to False or omitted, the system adjusts the name so that there are no collisions with existing components.

Table NewTable(String name, ColumnSet columns, Boolean exactName)

Creates new table component. Column set and exact name parameters are optional. When exact name is set to False or omitted, the system adjusts the name so that there are no collisions with existing components.

Terrain NewTerrain(String name, Surface surface, Boolean exactName)

Creates new terrain component for given surface. Exact name parameter is optional. When it is set to False or omitted, the system adjusts the name so that there are no collisions with existing components.

Theme NewTheme(String name, Component parent, Boolean exactName)

Creates new theme component linked to given drawing or theme. Exact name parameter is optional. When it is set to False or omitted, the system adjusts the name so that there are no collisions with existing components.

Zones NewZones(String name, CoordinateSystem system, Boolean exactName)

Creates new zones component. Coordinate system and exact name parameters are optional. When it is set to False or omitted, the system adjusts the name so that there are no collisions with existing components.

Open(String fileName, Boolean saveChanges, Boolean readOnly)

Opens new document saving or discarding any pending changes.

Paste()

Pastes the contents of the Clipboard as new component.

PasteAs(ComponentType type)

Pastes the contents of the Clipboard as new component of the desired type.

RefreshAllLinked()

Refreshes all linked components.

RevertToSaved()

Reverts documents to last saved state if any.

Save()

Saves document.

SaveAs(String fileName)

Saves document with a new name.
UndoCheckOut(ComponentSet components)
Unused changes made to shared components and gets the latest version of the components from the Enterprise
server or servers in Enterprise Edition.

UndoCheckOutAll()
Undoes changes made to all shared components in the document and gets the latest version of the components
from the Enterprise server or servers in Enterprise Edition.

**Tech Note**

Prior to 6.50 SP1, the BatchUpdates property applied only to the active document (so, there was no method to
increase performance by batching updates in an external application or on a web site) and was global in that all
instances of the Document object referring to the MAP file opened in the UI were sharing the value of the
property. As of 6.50 SP1, the BatchUpdates property works for all documents and is scoped to a particular
document object.

That is,

Application.ActiveDocument.BatchUpdates = Xxx

...sets the property in a temporary instance of the Document object, which does not have any effect.

However,

Set doc = Application.ActiveDocument
doc.BatchUpdates = True
...
... * use data obtained from the "doc" object ...

...batches updates for all write operations in all objects retrieved from the "doc" object.

The new policy is both faster and more flexible.

**DocumentSet Object**

Set of documents.

**Properties**

Application Application
Returns application. Read only.

Number Count
Returns number of documents in set. Read only.

Document Item(Number index)
Returns document with given index. Read only.

Any Parent
Returns parent object. Read only.

**Methods**

Close(Boolean saveChanges)
Closes all documents within set except documents containing running scripts. If argument is omitted, the changes are saved.

Open(String fileName, Boolean readOnly)
Opens new document.

**Obtained From**

Application (DocumentSet)

**See Also**

Scripting Reference
**Drawing Object**

Drawing component.

**Properties**

Application Application
Returns application. Read only.

Format AreaBackground
Returns background color used for areas. Read only.

Format AreaBorderBackground
Returns border background color used for areas. Read only.

Format AreaBorderForeground
Returns border foreground color used for areas. Read only.

Format AreaBorderSize
Returns border size used for areas. Read only.

Format AreaBorderStyle
Returns border style used for areas. Read only.

Format AreaForeground
Returns foreground color used for areas. Read only.

Format AreaSize
Returns size used for areas. Read only.

Format AreaStyle
Returns style used for areas. Read only.

Color BackgroundColor
Sets or returns background color. Read / write.

Rect Box
Returns bounding box of all objects. Read only.

Boolean Cached
Sets or returns caching option for shared component in Enterprise Edition. Read/write.

Boolean CanAddObjects
Returns True if the drawing supports adding new objects and False otherwise. Read only.

Boolean CanAlterObjects
Returns True if the drawing supports altering object metric and False otherwise. Read only.

Boolean CanHaveLinkArea
Returns True if the linked drawing supports setting the area of interest and False otherwise. Read only.

Boolean CanRemoveObjects
Returns True if the drawing supports removing objects and False otherwise. Read only.
ControlPointSet ControlPointSet
Returns set of control points. Read only.

CoordinateSystem CoordinateSystem
Sets or returns coordinate system. Read/write.

Boolean CoordinateSystemVerified
Checks whether or not the component coordinate system has been verified by the user, or alters the verification state. Read/write.

View DefaultView
Returns default view. Read only.

String Description
Sets or returns component description. Read/write.

Document Document
Returns owner document. Read only.

Number Epsilon
Sets or returns location precision. Read/write.

Folder Folder
Sets or returns containing folder. Read/write.

Number GeometryVersion
Returns a numeric value representing the version of the geometry inside the drawing. Adding or removing drawing objects or altering their metric advances the version number. Read only.

Boolean HasLinkArea
Returns True if the linked drawing uses the area of interest and False otherwise. Read only.

Boolean HasLocalChanges
Returns True if the linked drawing contains data for one or more editing conflicts. Read only.

Number ID
Returns unique component ID. Read only.

Boolean IsCheckedOut
Checks if component is shared and checked out in Enterprise Edition. Read only.

Boolean IsCheckedOutRemotely
Checks if component is shared and checked out by another user in Enterprise Edition. Read only.

Boolean IsModified
Checks if component is modified since last save in Enterprise Edition. Read only.

Boolean IsOutdated
Checks if component is shared and there is a later version of the component on the Enterprise server in Enterprise Edition. Read only.

Boolean IsReadOnly
Checks if component is readonly (eg, shared and not checked out) in Enterprise Edition. Read only.
Boolean IsShared
Checks if component is shared on an Enterprise server in Enterprise Edition. Read only.

Boolean IsWritable
Checks if component is writable in Enterprise Edition. Read only.

DateTime LastRefreshed
Returns date and time of the last refresh for a linked component and the current date and time for a non-linked component.

Format LineBackground
Returns background color used for lines. Read only.

Format LineForeground
Returns foreground color used for lines. Read only.

Format LineSize
Returns size used for lines. Read only.

FormatLineStyle
Returns style used for lines. Read only.

Rect LinkArea
Returns the area of interest used by the linked drawing. If the drawing is not linked or does not use the area of interest, returns a rect with negative width or height. Read only.

Boolean LinkAreaRestrictive
Returns True if the linked drawing uses the area of interest and requires all objects to be completely within that area. Read only.

LinkEditMode LinkEditMode
Sets or returns the editing mode for the linked drawing. Read / write.

String LinkRowset
Returns the source rowset of a linked component. Read only.

String LinkSource
Returns the data source of a linked component. Read only.

String LinkTechnology
Returns the data access technology used by a linked component. Read only.

String Name
Sets or returns component name. Read/write.

String Note
Sets or returns notes associated with the component. Read/write.

ObjectSet ObjectSet
Returns set of drawing objects. Read only.

ComponentSet OwnedComponentSet
Returns set of components bound to this component. Read only.
ComponentSet OwnedLabelSet
Returns set of label components bound to this component. Read only.

ComponentSet OwnedLayoutSet
Returns set of layouts bound to this component. Read only.

Table OwnedTable
Returns table bound to this component. Read only.

Component Owner
Returns owner component if any. Read only.

Any Parent
Returns parent object. Read only.

Format PointBackground
Returns background color used for points. Read only.

Format PointForeground
Returns foreground color used for points. Read only.

Format PointRotation
Returns rotation used for points. Read only.

Format PointSize
Returns size used for points. Read only.

Format PointStyle
Returns style used for points. Read only.

Number RemoteVersion
Returns version of shared component available on the Enterprise server in Enterprise Edition. Read only.

DrawingSelectionSet SavedSelectionSet
Returns set of saved selections. Read only.

ObjectSet Selection
Returns set of selected drawing objects. Read only.

String Server
Returns server identification string for shared component in Enterprise Edition. Read only.

String ShareStatus
Returns textual report on component sharing status in Enterprise Edition. Read only.

ComponentType Type
Returns component type. Read only.

String TypeName
Returns textual representation of the component type. Read only.

Number Version
Returns version of shared component within the local project in Enterprise Edition. Read only.

ViewSet ViewSet
Returns set of views associated with this component. Read only.

Number ZoomMax
Sets or returns maximum zoom level. Read/write.

Number ZoomMin
Sets or returns minimum zoom level. Read/write.

Number ZoomRender
Sets or returns render zoom level. Read/write.

Methods

CheckIn()
Checks in changes made to a shared component to the Enterprise server in Enterprise Edition.

CheckOut()
Checks out a shared component for editing in Enterprise Edition.

Clear(Boolean selection)
Clears entire component or selection within the component. Calling the method without parameters clears entire component.

Boolean CommitLocalChanges()
Commits local changes to objects participating in editing conflicts in the linked drawing and uploads them to the data source. Returns True if all editing conflicts are resolved and False otherwise.

Copy(Boolean selection)
Copies entire component or selection within the component into the Clipboard. Calling the method without parameters copies entire component.

Cut(Boolean selection)
Copies entire component or selection within the component into the Clipboard and then clears it. Calling the method without parameters cuts entire component.

Boolean DiscardLocalChanges()
Discards local changes to objects participating in editing conflicts in the linked drawing and retrieves the latest data for these objects from the data source. Returns True if all editing conflicts are resolved and False otherwise.

GetLatestVersion()
Gets the latest version of a shared component from the Enterprise server in Enterprise Edition.

Boolean IsEmpty()
Returns True if drawing contains no objects and False otherwise.

Boolean IsLinked()
Returns True if drawing is linked and False otherwise.

Open()
Opens component.
OpenInNewWindow()
Opens component in new window.

Paste(Boolean replace)
Pastes the contents of the Clipboard into the component replacing current selection or leaving it intact. Calling the method without parameters replaces selection.

Print(Boolean useDialog)
Prints component.

ProjectTo(CoordinateSystem system)
Projects component to another coordinate system.

Boolean RefreshWithArea(Rect area, Boolean restrictive)
Refreshes a linked drawing using the specified area of interest. Does nothing if the drawing is not linked. Returns True if the refresh has succeeded and False otherwise.

RenderAreaTo(String name, Number width, Number height, Rect area, Boolean clean)
Renders component area into an image with given name, width and height. If last parameter is True, legend, north arrow and scale bar are not rendered even if they are on.

RenderTo(String name, Number width, Number height, Boolean clean)
Render component into an image with given name, width and height. If last parameter is True, legend, north arrow and scale bar are not rendered even if they are turned on.

Boolean Refresh()
Refreshes a linked component and does nothing for a non-linked component. In the case of a linked component returns True if the refresh has succeeded and False otherwise. Refreshing a table bound to a linked drawing refreshes the drawing and vice versa.

Boolean RefreshAfter(Number)
Refreshes a linked component if the component has not been refreshed for more than the given number of seconds.

SelectAll()
Selects all objects.

SelectInverse()
Selects objects that were not selected and vice versa.

SelectNone()
Unselects all objects.

UndoCheckOut()
Undoes changes made to a shared component and gets the latest version of the component from the Enterprise server in Enterprise Edition.

Unlink()
Unlinks component. If the component is not linked, does nothing.

Obtained From
Document (NewDrawing)

See Also
**DrawingSelectionSet Object**
Set of saved selections within drawing.

**Properties**

- **Application Application**
  Returns application. Read only.

- **Number Count**
  Returns number of selections in set. Read only.

- **ObjectSet Item(Number index)**
  Returns selection with given index. Read only.

- **Any Parent**
  Returns parent object. Read only.

**Methods**

- **Number ItemByMask(Number mask)**
  Returns index of selection with given mask value or -1.

- **Number ItemByName(String name)**
  Returns index of selection with given name or -1.

**Obtained From**

- **Drawing (SavedSelectionSet)**

**See Also**

- Scripting Reference
**DrawingWindow Object**

Drawing window.

**Properties**

Component `ActiveComponent`
Returns drawing component shown in window. Read only.

Object `ActiveObject`
Returns object selected for editing. Read only.

Application `Application`
Returns application. Read only.

Rect `Bounds`
Returns the area covered by the window, in the coordinate system of the displayed component. Read only.

Component `Component`
Returns drawing component shown in window. Read only.

Number `Height`
Returns window height in pixels. Read only.

Point `Location`
Sets or returns viewport center. Read/write.

Point `LocationLatLon`
Sets or returns viewport center in lat/lon coordinates. Read/write.

Any `Parent`
Returns parent object. Read only.

Number `Scale`
Sets or returns viewport scale (projected components only). Read/write.

Number `ScaleInternal`
Sets or returns internal pixel-to-data ratio. Read/write.

Number `Width`
Returns window width in pixels. Read only.

**Methods**

Close()
Closes window.

Boolean `HasActiveObject()`
Returns True if some object within the window is selected for editing and False otherwise.

Boolean `HasLocation()`
Returns True if viewport center can be modified and False otherwise.
Boolean HasScale()
Returns True if viewport scale can be obtained or modified and False otherwise.

Boolean HasScaleInternal()
Returns True.

MoveTo(Branch branch)
MoveTo(BranchSet branchSet)
MoveTo(Component component)
MoveTo(Geom geom)
MoveTo(Label label)
MoveTo(LabelSet labelSet)
MoveTo(Object object)
MoveTo(ObjectSet objectSet)
MoveTo(Pixel pixel)
MoveTo(PixelSet pixelSet)
MoveTo(Point point)
MoveTo(PointSet pointSet)
MoveTo(Rect rect)
Centers viewport on given object or set of objects. Branches, geoms, points, rects and their sets are assumed to be in the coordinate system of the displayed component.

MoveToLocation(Point point, Boolean latLon)
Centers viewport on given location. LatLon parameter is optional.

Refresh()
Updates window contents.

RenderTo(String name)
Renders window into an image with given name.

ZoomTo(Branch branch)
ZoomTo(BranchSet branchSet)
ZoomTo(Component component)
ZoomTo(Geom geom)
ZoomTo(Label label)
ZoomTo(LabelSet labelSet)
ZoomTo(Object object)
ZoomTo(ObjectSet objectSet)
ZoomTo(Pixel pixel)
ZoomTo(PixelSet pixelSet)
ZoomTo(Point point)
ZoomTo(PointSet pointSet)
ZoomTo(Rect rect)
Zooms to given object or set of objects. Branches, geoms, points, rects and their sets are assumed to be in the coordinate system of the displayed component. If the bounding box of the object is a point (for example, if the object is a point), centers viewport on given object.

Obtained From
WindowSet (Item, ActiveWindow)

**DSSAtom Object**
Atomic ranking expression used to build rank columns.

**Properties**

- **Application Application**
  Returns application. Read only.

- **Number Average**
  Returns average value used in atom. Read/write.

- **Column Column**
  Sets or returns owner column. Read/write.

- **Number Dispersion**
  Returns dispersion value used in atom. Read/write.

- **Number ID**
  Returns unique atom ID. Read only.

- **String Name**
  Sets or returns atom name. Read/write.

- **Any Parent**
  Returns parent object. Read only.

- **PointSet Points**
  Returns metric of the atom curve. Read only.

- **Boolean RefreshAverage**
  Sets or returns refresh option for average value. Read/write.

- **Boolean RefreshDispersion**
  Sets or returns refresh option for dispersion value. Read/write.

- **DSSAtomType Type**
  Returns atom type. Read only.

**Methods**

- **MakeAverage(Number average, Number dispersion)**
  Initializes atom with bell curve with given average and dispersion.

- **MakeCurve(PointSet points)**
  Initializes atom with arbitrary curve.

- **MakeHigh(Number average, Number dispersion)**
  Initializes atom with right elbow with given average and dispersion.

- **MakeLow(Number average, Number dispersion)**
  Initializes atom with left elbow with given average and dispersion.

Scripting Reference
DSSAtomSet Object
Set of atomic ranking expressions used to build rank columns.

Properties

Application Application
Returns application. Read only.

Number Count
Returns number of atoms in set. Read only.

DSSAtom Item(Number index)
DSSAtom Item(String name)
Returns atom with given index or name. Read only.

DSSAtom LastAdded
Returns last added atom. Read only.

Any Parent
Returns parent object. Read only.

Methods

Add(DSSAtom atom)
Appends atom to atom set.

Number ItemByID(Number id)
Returns index of atom with given ID or -1.

Number ItemByName(String name)
Returns index of atom with given name or -1.

DSSAtom NewDSSAtom()
Returns new atom that can later be added to atom set.

Remove(Number index)
Removes atom with given index.

RemoveAll()
Removes all atoms.

Obtained From

Table (DSSAtomSet)

See Also

Scripting Reference
**DSSQuery Object**
Set of ranking expressions.

**Properties**

- Application Application
  Returns application. Read only.

- Number Count
  Returns number of expressions in set. Read only.

- DSSQueryEntry Item(Number index)
  Returns expression with given index. Read only.

- DSSQueryEntry LastAdded
  Returns last added expression if any. Read only.

- Any Parent
  Returns parent object. Read only.

**Methods**

- Add(DSSQueryEntry queryEntry)
  Appends ranking expression to set.

- DSSQueryEntry NewDSSQueryEntry()
  Returns new expression that can later be added to set.

- Remove(Number index)
  Removes expression with given index.

**Obtained From**

- Column (DSSQuery)

**See Also**

Scripting Reference
DSSQueryEntry Object
Ranking expression used to build rank columns.

Properties

Application Application
Returns application. Read only.

DSSAtom Atom
Sets or returns atom. Read/write.

DSSHedge Hedge
Sets or returns atom hedge. Read/write.

DSSJunction Junction
Sets or returns junction to next atom in query. Read/write.

Boolean Not
Sets or returns negation flag. Read/write.

Any Parent
Returns parent object. Read only.

Obtained From

DSSQuery (Item, LastAdded, NewDSSQueryEntry)

See Also

Scripting Reference
Elevation Object
Elevation component.

Properties

Application
Returns application. Read only.

Color
BackgroundColor
Sets or returns background color. Read / write.

Boolean
Cached
Sets or returns caching option for shared component in Enterprise Edition. Read/write.

Boolean
Coordinates
Turns coordinate display on or off. Read/write.

String
Description
Sets or returns component description. Read/write.

Boolean
DistanceLabels
Turns labels for coordinate distances on or off. Read/write.

Boolean
DistanceLabelsEven
Turns labels for even distances on or off. Read/write.

Number
DistanceLabelsDigits
Sets or returns the number of decimal digits used for distance labels. Read/write.

Document
Document
Returns owner document. Read only.

Folder
Folder
Sets or returns containing folder. Read/write.

Boolean
HeightLabels
Turns labels for coordinate heights on or off. Read/write.

Boolean
HeightLabelsBounds
Turns labels for minimum and maximum heights on or off. Read/write.

Boolean
HeightLabelsBreaks
Turns labels for surface breaks on or off. Read/write.

Boolean
HeightLabelsEven
Turns labels for even heights on or off. Read/write.

Number
HeightLabelsDigits
Sets or returns the number of decimal digits used for height labels. Read/write.

Number
ID
Returns unique component ID. Read only.
Boolean IsCheckedOut
Checks if component is shared and checked out in Enterprise Edition. Read only.

Boolean IsCheckedOutRemotely
Checks if component is shared and checked out by another user in Enterprise Edition. Read only.

Boolean IsModified
Checks if component is modified since last save in Enterprise Edition. Read only.

Boolean IsOutdated
Checks if component is shared and there is a later version of the component on the Enterprise server in Enterprise Edition. Read only.

Boolean IsReadOnly
Checks if component is readonly (eg, shared and not checked out) in Enterprise Edition. Read only.

Boolean IsShared
Checks if component is shared on an Enterprise server in Enterprise Edition. Read only.

Boolean IsWritable
Checks if component is writable in Enterprise Edition. Read only.

String Name
Sets or returns component name. Read/write.

String Note
Sets or returns notes associated with the component. Read/write.

ComponentSet OwnedComponentSet
Returns set of components bound to this component. Read only.

ComponentSet OwnedLayoutSet
Returns set of layouts bound to this component. Read only.

Component Owner
Returns owner component if any. Read only.

Any Parent
Returns parent object. Read only.

Number RemoteVersion
Returns version of shared component available on the Enterprise server in Enterprise Edition. Read only.

String Server
Returns server identification string for shared component in Enterprise Edition. Read only.

Boolean Shading
Turns color shading on or off. Read/write.

String ShareStatus
Returns textual report on component sharing status in Enterprise Edition. Read only.
ComponentType Type
Returns component type. Read only.

String TypeName
Returns textual representation of the component type. Read only.

Number Version
Returns version of shared component within the local project in Enterprise Edition. Read only.

Boolean ZeroHeight
Includes or excludes zero height. Read/write.

**Methods**

CheckIn()
Checks in changes made to a shared component to the Enterprise server in Enterprise Edition.

CheckOut()
Checks out a shared component for editing in Enterprise Edition.

Copy()
Copies component into the Clipboard.

GetLatestVersion()
Gets the latest version of a shared component from the Enterprise server in Enterprise Edition.

Open()
Opens component.

OpenInNewWindow()
Opens component in new window.

Print(Boolean useDialog)
Prints component.

RenderTo(String name, Number width, Number height)
Render component into an image with given name, width and height.

UndoCheckOut()
Undoes changes made to a shared component and gets the latest version of the component from the Enterprise server in Enterprise Edition.

Scripting Reference
Ellipsoid Object
Ellipsoid.

Properties

Application
Returns application. Read only.

Number Eccentricity
Returns eccentricity. Read/write.

Number MajorAxis
Returns major axis in meters. Read/write.

Number MinorAxis
Returns minor axis in meters. Read/write.

String Name
Returns ellipsoid name. Read only.

Any Parent
Returns parent object. Read only.

Methods

Load(String name)
Loads ellipsoid using given name.

Obtained From

Application (DefaultEllipsoid, NewEllipsoid)
Datum (Ellipsoid)
EllipsoidSet (Item)

See Also

Scripting Reference
EllipsoidSet Object
Set of ellipsoids.

Properties

Application
Application Application
Returns application. Read only.

Number Count
Returns number of ellipsoids in set. Read only.

Ellipsoid Item(Number index)
Ellipsoid Item(String name)
Returns ellipsoid with given index or name. Read only.

Any Parent
Returns parent object. Read only.

Methods

Number ItemByName(String name)
Returns index of ellipsoid with given name or -1.

Obtained From

Application (EllipsoidSet)

Scripting Reference
EventArgs Object
Arguments for application-wide events.

Properties

Application Application
Returns application object. Read only.

Boolean Handled
Sets or returns handled flag. Setting this property to True will cancel further processing of an event by the system. Read/write.

Label Label
Returns context label if any. Read only.

Point LocationLatLon
Returns event location in lat/lon coordinates. Read only.

Point LocationNative
Returns event location in coordinates of the context component. Read only.

Point LocationScreen
Returns event location in window coordinates. Read only.

Object Object
Returns context object if any. Read only.

Any Parent
Returns parent object. Read only.

Methods

Boolean HasLabel()
Returns True if the event has a context label and False otherwise.

Boolean HasObject()
Returns True if the event has a context object and False otherwise.

See Also

Scripting Reference
Export Object
Generic exporter.

Properties

Application Application
Returns application. Read only.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string (eg. "Text Files (*.txt)"). Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of export properties. Read only.

Methods

Boolean CanExport(ComponentType type)
Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
Exports given component to a file.

Obtained From

Application (NewExport)

See Also

Scripting Reference
ExportAdoNet Object

ADO.NET export.

Properties

Application Application
Returns application. Read only.

String ConnectionString
Sets or returns connection string. Read/write.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of export properties. Read only.

Methods

Boolean CanExport(ComponentType type)
Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
Exports given component to a file.

Obtained From

Application (NewExport("ADO.NET"))

See Also

Scripting Reference
ExportAdoNetOdbc Object
ADO.NET ODBC export.

**Properties**

Application Application
Returns application. Read only.

String ConnectionString
Sets or returns connection string. Read/write.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of export properties. Read only.

**Methods**

Boolean CanExport(ComponentType type)
Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
Exports given component to a file.

**Obtained From**

Application (NewExport("ADO.NET ODBC"))

**See Also**

Scripting Reference
ExportAdoNetOleDb Object

ADO.NET OLE DB export.

Properties

Application Application
  Returns application. Read only.

String ConnectionString
  Sets or returns connection string. Read/write.

  Returns default file extension. Read only.

String Filter
  Returns filter string. Read only.

String Name
  Returns file format name. Read only.

Any Parent
  Returns parent object. Read only.

ConverterPropertySet PropertySet
  Returns set of export properties. Read only.

Methods

String BuildConnectionString(String server, String login, String password)
  Composes a connection string for Oracle ADO.NET provider. The last two arguments are optional.

Boolean CanExport(ComponentType type)
  Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
  Exports given component to a file.

Obtained From

  Application (NewExport("ADO.NET Oracle"))

ADO.NET SQL Server export.

**Properties**

Application Application
   Returns application. Read only.

String ConnectionString
   Sets or returns connection string. Read/write.

String DefaultExtension
   Returns default file extension. Read only.

String Filter
   Returns filter string. Read only.

String Name
   Returns file format name. Read only.

Any Parent
   Returns parent object. Read only.

ConverterPropertySet PropertySet
   Returns set of export properties. Read only.

**Methods**

String BuildConnectionString(String server, String login, String password, String database)
   Composes a connection string for SQL Server ADO.NET provider. The last three arguments are optional.

Boolean CanExport(ComponentType type)
   Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
   Exports given component to a file.

**Obtained From**

Application (NewExport("ADO.NET SQL Server"))

**See Also**

Scripting Reference
ExportAi Object
Adobe Illustrator AI exporter.

Properties

Application Application
Returns application. Read only.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of export properties. Read only.

Boolean VectorText
Toggles the conversion of text element into vector shapes. Read/write.

Methods

Boolean CanExport(ComponentType type)
Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
Exports given component to a file.

Obtained From

Application (NewExport("AI"))

See Also

Scripting Reference
ExportBil Object
BIL exporter.

Properties

Application Application
Returns application. Read only.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of export properties. Read only.

Methods

Boolean CanExport(ComponentType type)
Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
Exports given component to a file.

Obtained From

Application (NewExport("BIL"))

See Also

Scripting Reference
**ExportBmp Object**
BMP exporter.

**Properties**

Application Application
Returns application. Read only.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of export properties. Read only.

**Methods**

Boolean CanExport(ComponentType type)
Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
Exports given component to a file.

**Obtained From**

Application (NewExport("BMP"))

**See Also**

Scripting Reference
ExportCsv Object
CSV exporter.

**Properties**

Application Application
Returns application. Read only.

ConverterItemSet Columns
Returns set of export columns. Read only.

ConvertPolicy ConvertPolicy
Sets or returns column export policy. Read/write.

String DefaultExtension
Returns default file extension. Read only.

Boolean EndingComma
Sets or returns ending comma option. If option is set to True, the system writes an extra comma at the end of each line. Read/write.

String Filter
Returns filter string. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of export properties. Read only.

Boolean Quotes
Sets or returns quoting option. If option is set to True, the system encloses values in quotation marks regardless of their type. Read/write.

**Methods**

Boolean CanExport(ComponentType type)
Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
Exports given component to a file.

**Obtained From**

Application (NewExport("CSV"))

Sets or returns column export policy. Read/write.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of export properties. Read only.

SubtypeDb Subtype
Sets or returns subtype of export file. Read/write.

**Methods**

Boolean CanExport(ComponentType type)
Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
Exports given component to a file.

**Obtained From**

Application (NewExport("DB"))

**See Also**

Scripting Reference
ExportDb2 Object
Native DB2 export.

Properties

Application Application
  Returns application. Read only.

String ConnectionString
  Sets or returns connection string. Read/write.

String DefaultExtension
  Returns default file extension. Read only.

String Filter
  Returns filter string. Read only.

String Name
  Returns file format name. Read only.

Any Parent
  Returns parent object. Read only.

ConverterPropertySet PropertySet
  Returns set of export properties. Read only.

Methods

String BuildConnectionString(String server, String login, String password)
  Composes a connection string for DB2 native client. The last two arguments are optional.

Boolean CanExport(ComponentType type)
  Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String connectionString, ConvertPrompt prompt)
  Exports given component.

Obtained From

Application (NewExport("DB2"))

ExportEmfGdi Object
EMF (GDI) exporter for layouts.

Properties

Application Application
Returns application object. Read only.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

Boolean IgnoreStyles
Toggles the use of style information for drawing objects and labels. Read/write.

String Name
Returns file format name. Read only.

Number Page
Sets or returns exported page for a multipage layout. Read/write.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of export properties. Read only.

Number Resolution
Sets or returns pixel resolution in dots per inch (DPI). Read/write.

Number VectorResolution
Sets or returns vector resolution in dots per inch (DPI). Read/write.

Methods

Boolean CanExport(ComponentType type)
Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
Exports given component to a file.

Obtained From

Application (NewExport("EMF (GDI)"))

Properties

Application Application
Returns application. Read only.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of export properties. Read only.

Methods

Boolean CanExport(ComponentType type)
Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
Exports given component to a file.

Obtained From

Application (NewExport("GIF"))

See Also

Scripting Reference
ExportGrd Object
ESRI ASCII grid exporter.

Properties

Application Application
Returns application. Read only.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of export properties. Read only.

Methods

Boolean CanExport(ComponentType type)
Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
Exports given component to a file.

Obtained From

Application (NewExport("GRD") or NewExport("ESRI ASCII Grid"))

See Also

Scripting Reference
ExportGrdSurfer6 Object
Surfer 6 GRD exporter.

Properties

Application Application
Returns application. Read only.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of export properties. Read only.

Methods

Boolean CanExport(ComponentType type)
Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
Exports given component to a file.

Obtained From

Application (NewExport("Surfer 6 GRD"))

See Also

Scripting Reference
**ExportGrdSurfer7 Object**

Surfer 7 GRD exporter.

**Properties**

- **Application Application**
  Returns application. Read only.

- **String DefaultExtension**
  Returns default file extension. Read only.

- **String Filter**
  Returns filter string. Read only.

- **String Name**
  Returns file format name. Read only.

- **Any Parent**
  Returns parent object. Read only.

- **ConverterPropertySet PropertySet**
  Returns set of export properties. Read only.

**Methods**

- **Boolean CanExport(ComponentType type)**
  Returns True if exporter can save components of given type and False otherwise.

- **Export(Component component, String fileName, ConvertPrompt prompt)**
  Exports given component to a file.

**Obtained From**

- Application (NewExport("Surfer 7 GRD"))

**See Also**

- Scripting Reference
ExportGrdSurferAscii Object
Surfer ASCII GRD exporter.

Properties

Application Application
Returns application. Read only.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of export properties. Read only.

Methods

Boolean CanExport(ComponentType type)
Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
Exports given component to a file.

Obtained From

Application (NewExport("Surfer ASCII GRD"))

See Also

Scripting Reference
ExportHtml Object
HTML exporter.

Properties

Application Application
Returns application. Read only.

ConverterItemSet Columns
Returns set of export columns. Read only.

ConvertPolicy ConvertPolicy
Sets or returns column export policy. Read/write.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of export properties. Read only.

Methods

Boolean CanExport(ComponentType type)
Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
Exports given component to a file.

Obtained From

Application (NewExport("HTML"))

See Also

Scripting Reference
ExportJpeg Object
JPEG exporter.

Properties

Application Application
Returns application. Read only.

JpegCompression Compression
Sets or returns JPEG compression method. Read/write.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of export properties. Read only.

JpegQuality Quality
Sets or returns JPEG compression quality. Read/write.

Number Scans
Sets or returns the number of scans used for compression. Read/write.

Methods

Boolean CanExport(ComponentType type)
Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
Exports given component to a file.

Obtained From

Application (NewExport("JPEG"))

See Also

Scripting Reference
ExportKml Object
KML export.

Properties

Application Application
Returns application. Read only.

String ColumnDescription
Sets or returns the name of a column with object descriptions. Read/write.

String ColumnName
Sets or returns the name of a column with object names. Read/write.

String ColumnZ
Sets or returns the name of a column with height data. Read/write.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

Boolean RelativeZ
Sets or returns the value of the relative heights option used with height data. If True, heights are relative, otherwise they are absolute. Read/write.

Methods

Boolean CanExport(ComponentType type)
Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String filename, ConvertPrompt prompt)
Exports given component to a file.

Obtained From

Application (NewExport("KML "))

See Also

Scripting Reference
ExportMdb Object

MDB exporter.

Properties

Application
Returns application. Read only.

Columns
Returns set of export columns. Read only.

ConvertPolicy
Sets or returns column export policy. Read/write.

DefaultExtension
Returns default file extension. Read only.

Filter
Returns filter string. Read only.

Name
Returns file format name. Read only.

Parent
Returns parent object. Read only.

PropertySet
Returns set of export properties. Read only.

Subtype
Sets or returns subtype of export file. Read/write.

Methods

CanExport(ComponentType type)
Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
Exports given component to a file.

Obtained From

Application (NewExport("MDB"))

See Also

Scripting Reference
ExportMfd Object
MFD exporter.

Properties

Application Application
Returns application. Read only.

ConverterItemSet Columns
Returns set of export columns. Read only.

ConvertPolicy ConvertPolicy
Sets or returns column export policy. Read/write.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of export properties. Read only.

Methods

Boolean CanExport(ComponentType type)
Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
Exports given component to a file.

Obtained From

Application (NewExport("MFD"))

See Also

Scripting Reference
ExportMif Object
MIF exporter.

Properties

Application Application
Returns application. Read only.

ConverterItemSet Columns
Returns set of export columns. Read only.

ConvertPolicy ConvertPolicy
Sets or returns column export policy. Read/write.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of export properties. Read only.

Methods

Boolean CanExport(ComponentType type)
Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
Exports given component to a file.

Obtained From

Application (NewExport("MIF"))

See Also

Scripting Reference
ExportOdbc Object
ODBC export.

Properties

Application Application
  Returns application. Read only.

String ConnectionString
  Sets or returns connection string. Read/write.

String DefaultExtension
  Returns default file extension. Read only.

String Filter
  Returns filter string. Read only.

String Name
  Returns file format name. Read only.

Any Parent
  Returns parent object. Read only.

ConverterPropertySet PropertySet
  Returns set of export properties. Read only.

Methods

Boolean CanExport(ComponentType type)
  Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
  Exports given component to a file.

Obtained From

Application (NewExport("ODBC"))

See Also

Scripting Reference
ExportOleDb Object
OLE DB export.

Properties

Application Application
Returns application. Read only.

String ConnectionString
Sets or returns connection string. Read/write.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of export properties. Read only.

Methods

Boolean CanExport(ComponentType type)
Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
Exports given component to a file.

Obtained From

Application (NewExport("OLEDB"))

See Also

Scripting Reference
ExportOracle Object
Native Oracle export.

Properties

Application Application
   Returns application. Read only.

String ConnectionString
   Sets or returns connection string. Read/write.

String DefaultExtension
   Returns default file extension. Read only.

String Filter
   Returns filter string. Read only.

String Name
   Returns file format name. Read only.

Any Parent
   Returns parent object. Read only.

ConverterPropertySet PropertySet
   Returns set of export properties. Read only.

Methods

String BuildConnectionString(String server, String login, String password)
   Composes a connection string for Oracle native client. The last two arguments are optional.

Boolean CanExport(ComponentType type)
   Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String connectionString, ConvertPrompt prompt)
   Exports given component.

Obtained From

Application (NewExport("Oracle"))

See Also

Scripting Reference
ExportPdf Object
PDF exporter for layouts.

Properties

Application Application
Returns application object. Read only.

Boolean Compression
Toggles compression. Read/write.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

Boolean IgnoreStyles
Toggles the use of style information for drawing objects and labels. Read/write.

Boolean Layers
Toggles the generation of layers. Read/write.

String Name
Returns file format name. Read only.

String PageFilter
Sets or returns page filter (eg, "1-5,8"). Read/write.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of export properties. Read only.

Number Resolution
Sets or returns pixel resolution in dots per inch (DPI). Read/write.

Boolean Transparency
Toggles support for transparency. Read/write.

Number VectorResolution
Sets or returns vector resolution in dots per inch (DPI). Read/write.

Boolean VectorText
Toggles the conversion of text element into vector shapes. Read/write.

Methods

Boolean CanExport(ComponentType type)
Returns True if exporter can save components of given type and False otherwise.
Export(Component component, String fileName, ConvertPrompt prompt)
Exports given component to a file.

**Obtained From**

Application (NewExport("PDF"))

**See Also**

Scripting Reference
ExportPng Object
PNG exporter.

Properties

Application
Returns application. Read only.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

Boolean Interlaced
Sets or returns interlaced option. Read/write.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet
Returns set of export properties. Read only.

Methods

Boolean CanExport(ComponentType type)
Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
Exports given component to a file.

Obtained From

Application (NewExport("PNG"))

**ExportPostgreSQL Object**
Native PostgreSQL export.

**Properties**

- **Application Application**
  Returns application. Read only.

- **ConnectionString**
  Sets or returns connection string. Read/write.

- **DefaultExtension**
  Returns default file extension. Read only.

- **Filter**
  Returns filter string. Read only.

- **Name**
  Returns file format name. Read only.

- **Parent**
  Returns parent object. Read only.

- **PropertySet**
  Returns set of export properties. Read only.

**Methods**

- **BuildConnectionString(String server, String login, String password, String database)**
  Composes a connection string for PostgreSQL native client. All arguments except server are optional.

- **CanExport(ComponentType type)**
  Returns True if exporter can save components of given type and False otherwise.

- **Export(Component component, String connectionString, ConvertPrompt prompt)**
  Exports given component.

**Obtained From**

- Application (NewExport("PostgreSQL"))

ExportPs Object

PS exporter for layouts.

Properties

Application Application
  Returns application object. Read only.

String DefaultExtension
  Returns default file extension. Read only.

Boolean ExplicitMask
  Toggles the use of explicit image mask for invisible pixels. Read/write.

String Filter
  Returns filter string. Read only.

Boolean IgnoreStyles
  Toggles the use of style information for drawing objects and labels. Read/write.

String Name
  Returns file format name. Read only.

String PageFilter
  Sets or returns page filter (eg, "1-5,8"). Read/write.

Any Parent
  Returns parent object. Read only.

PsPixelEncoding PixelEncoding
  Sets or returns pixel encoding. Read/write.

ConverterPropertySet PropertySet
  Returns set of export properties. Read only.

Number Resolution
  Sets or returns pixel resolution in dots per inch (DPI). Read/write.

Number VectorResolution
  Sets or returns vector resolution in dots per inch (DPI). Read/write.

Methods

Boolean CanExport(ComponentType type)
  Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
  Exports given component to a file.

Obtained From

Application (NewExport("PS"))

Scripting Reference
ExportSdts Object
SDTS exporter.

Properties

Application Application
Returns application. Read only.

ConverterItemSet Columns
Returns set of export columns. Read only.

ConvertPolicy ConvertPolicy
Sets or returns column export policy. Read/write.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

Number LineLimit
Sets or returns maximum number of coordinates per line object in range from 100 to 5000. Default value is 2000. Read/write.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of export properties. Read only.

Methods

Boolean CanExport(ComponentType type)
Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
Exports given component to a file.

Obtained From

Application (NewExport("SDTS"))

ExportTiff Object
TIFF exporter.

Properties

Application Application
Returns application. Read only.

ByteOrder ByteOrder
Sets or returns byte order. Read/write.

TiffCompression Compression
Sets or returns compression method. Read/write.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of export properties. Read only.

Boolean UseProjection
Sets or returns projection export option. Read/write.

Methods

Boolean CanExport(ComponentType type)
Returns True if exporter can save components of given type and False otherwise.

Export(Component component, String fileName, ConvertPrompt prompt)
Exports given component to a file.

Obtained From

Application (NewExport("TIFF"))

Folder component.

**Properties**

- **Application Application**
  Returns application. Read only.

- **ComponentSet Children**
  Returns set of contained components. Read only.

- **String Description**
  Sets or returns component description. Read/write.

- **Document Document**
  Returns owner document. Read only.

- **Folder Folder**
  Sets or returns containing folder. Read/write.

- **Number ID**
  Returns unique component ID. Read only.

- **String Name**
  Sets or returns component name. Read/write.

- **String Note**
  Sets or returns notes associated with the component. Read/write.

- **Component Owner**
  Returns owner component if any. Read only.

- **Any Parent**
  Returns parent object. Read only.

- **ComponentType Type**
  Returns component type. Read only.

- **String TypeName**
  Returns textual representation of the component type. Read only.

**Methods**

- **Boolean IsEmpty()**
  Returns True if folder does not contain any components and False otherwise.

- **Open()**
  Opens component.

- **OpenInNewWindow()**
  Opens component in new window.

Font Object

Font.

Properties

Boolean Bold
Sets or returns font bold option. Read/write.

Number Charset
Sets or returns font character set. Read/write.

Boolean Italic
Sets or returns font italic option. Read/write.

String Name
Sets or returns font facename. Read/write.

Number Size
Sets or returns font size in points. Read/write.

Boolean Strikethrough
Sets or returns font strikethrough option. Read/write.

Boolean Underline
Sets or returns font underline option. Read/write.

Number Weight
Sets or returns font weight. Read/write.

Methods

Font Clone()
Returns a copy of subject font.

Boolean IsEqual(Font font)
Returns True if subject font is equal to given font and False otherwise.

Events

FontChanged(String property)
Called when font has changed.

Obtained From

Font (Clone)
LayoutEntry (BorderFont, Font)

See Also

Scripting Reference
Form Object
Form component.

Properties

Application
Returns application. Read only.

String Description
Sets or returns component description. Read/write.

Document
Returns owner document. Read only.

Folder
Sets or returns containing folder. Read/write.

Number ID
Returns unique component ID. Read only.

String Name
Sets or returns component name. Read/write.

String Note
Sets or returns notes associated with the component. Read/write.

ComponentSet
Returns set of components bound to this component. Read only.

Component Owner
Returns owner component if any. Read only.

Any Parent
Returns parent object. Read only.

Any Result
Sets or returns form exit code. Read/write.

ComponentType
Returns component type. Read only.

String TypeName
Returns textual representation of the component type. Read only.

Methods

DoEvents()
Handles all pending events.

Open()
Opens component.
OpenInNewWindow()
Opens component in new window.

Run()
Runs form.

**Obtained From**

Document (NewForm)

**Comments**

Due to potential deadlock issues, it is recommended that one clears the Result property after invoking the form if it is known to contain a reference to an object, like a Component or Application object.

The DoEvents method is used to handle all pending events, for example, to allow canceling a lengthy operation.

**See Also**

Scripting Reference
Format Object
Set of formatting rules.

Properties

Application Application
Returns application. Read only.

Column Column
Returns column of a thematic formatting. Read only.

Component Component
Returns owner component. Read only.

FormatValue DefaultValue
Returns default format value. Read only.

FormatValue MaxValue
Returns format value applied to highest interval in interval-based thematic formatting. Read only.

FormatValue MinValue
Returns format value applied to lowest interval in interval-based thematic formatting. Read only.

Any Parent
Returns parent object. Read only.

FormatType Type
Returns formatting type. Read only.

FormatValueSet Values
Returns a set of format values. Read only.

Methods

Boolean IsConstant()
Returns True if formatting is not based on a column and False otherwise.

Boolean IsInitialized()
Returns True if formatting is initialized and False otherwise.

LoadFrom(String xml, Boolean loadColumn)
Loads formatting from given XML code. The last parameter is optional. If it is set to False or omitted, column data is not loaded.

LoadFromFile(String path, Boolean loadColumn)
Loads formatting from given XML file. The last parameter is optional. If it is set to False or omitted, column data is not loaded.

SaveToFile(String path)
Saves formatting to given XML file. If file already exists, it gets overwritten.

Set(Color value)
Set(Number value)
Unbinds formatting from any column it may have been bound to and sets the default format value to given color or number.

SetEqCount(Column column, Number breaks, Number alignment)
SetEqCount(Number id, Number breaks, Number alignment)
SetEqCount(String name, Number breaks, Number alignment)

Binds formatting to given column using "Equal Count" with specified number of intervals. Column can be supplied directly or by its ID or name. The last parameter is the decimal alignment (a value of 1 aligns numeric values to 10, a value of -1 aligns to 0.1, a value of -2 aligns to 0.01, the default value is 0 and aligns to whole numbers).

SetEqIntervals(Column column, Number breaks, Number alignment)
SetEqIntervals(Number id, Number breaks, Number alignment)
SetEqIntervals(String name, Number breaks, Number alignment)

Binds formatting to given column using "Equal Intervals" with specified number of intervals. Column can be supplied directly or by its ID or name. The last parameter is the decimal alignment (a value of 1 aligns numeric values to 10, a value of -1 aligns to 0.1, a value of -2 aligns to 0.01, the default value is 0 and aligns to whole numbers).

SetExpIntervals(Column column, Number breaks, Number alignment)
SetExpIntervals(Number id, Number breaks, Number alignment)
SetExpIntervals(String name, Number breaks, Number alignment)

Binds formatting to given column using "Exponential Intervals" with specified number of intervals. Column can be supplied directly or by its ID or name. The last parameter is the decimal alignment (a value of 1 aligns numeric values to 10, a value of -1 aligns to 0.1, a value of -2 aligns to 0.01, the default value is 0 and aligns to whole numbers).

SetNaturalBreaks(Column column, Number breaks, Number alignment)
SetNaturalBreaks(Number id, Number breaks, Number alignment)
SetNaturalBreaks(String name, Number breaks, Number alignment)

Binds formatting to given column using "Natural Breaks" with specified number of breaks. Column can be supplied directly or by its ID or name. The last parameter is the decimal alignment (a value of 1 aligns numeric values to 10, a value of -1 aligns to 0.1, a value of -2 aligns to 0.01, the default value is 0 and aligns to whole numbers).

SetStDevIntervals(Column column, Number breaks, Number alignment)
SetStDevIntervals(Number id, Number breaks, Number alignment)
SetStDevIntervals(String name, Number breaks, Number alignment)

Binds formatting to given column using "Standard Intervals" with specified number of intervals. Column can be supplied directly or by its ID or name. The last parameter is the decimal alignment (a value of 1 aligns numeric values to 10, a value of -1 aligns to 0.1, a value of -2 aligns to 0.01, the default value is 0 and aligns to whole numbers).

SetUniqueValues(Column column)
SetUniqueValues(Number id)
SetUniqueValues(String name)

Binds formatting to given column using "Unique Values". Column can be supplied directly or by its ID or name.

String ToXML()
Saves formatting to XML string.

Obtained From

Drawing (AreaBackground, AreaForeground, AreaSize, AreaStyle, LineBackground, LineForeground, LineSize, LineStyle, PointBackground, PointForeground, PointRotation, PointSize, PointStyle)
Labels (LabelBackground, LabelForeground, LabelRotation, LabelSize, LabelStyle)

See Also
Scripting Reference
FormatValue Object
Format value representing single color, size or style.

Properties

Application Application
Returns application. Read only.

Color Formatting or

Number Formatting
Sets or returns formatting (color or number). Read / write.

Any Parent
Returns parent object. Read only.

String Value
Returns unique value the formatting is bound to. Read only.

Number ValueLower
Returns numeric value representing the lower bound of the formatting interval. Read only.

Number ValueUpper
Returns numeric value representing the upper bound of the formatting interval. Read only.

Obtained From

FormatValueSet (Item property)
Format (DefaultValue, MinValue, MaxValue)

See Also

Scripting Reference
**FormatValueSet Object**
Set of format values for a thematic formatting.

**Properties**

Application Application
Returns application. Read only.

Number Count
Returns the number of format values. Read only.

FormatValue Item(Number index)
Returns format value with given index. Read only.

Any Parent
Returns parent object. Read only.

**Obtained From**

Format (Values)

**See Also**

Scripting Reference
**GeocodeMatch Object**
Geocoding match.

**Properties**

String Address
Returns match street address. Read only.

Application Application
Returns application. Read only.

String City
Returns match city. Read only.

String Country
Returns match country. Read only.

Number Latitude
Returns match latitude on a WGS84 datum. Read only.

GeocodeLevel Level
Returns match level. Read only.

String LevelText
Returns textual description of match level. Read only.

Number Longitude
Returns match longitude on a WGS84 datum. Read only.

Any Parent
Returns parent object. Read only.

String State
Returns match state. Read only.

GeocodeStatus Status
Returns match status. Read only.

String StatusText
Returns textual description of match status. Read only.

String Zip
Returns match zip code. Read only.

**Obtained From**

GeocodeMatchSet (Item)

**See Also**

Scripting Reference
**GeocodeMatchSet Object**
Set of geocoding matches.

**Properties**

Application Application
  Returns application. Read only.

Number Count
  Returns number of matches in set. Read only.

GeocodeMatch Item(Number index)
  Returns match with specified index. Read only.

Any Parent
  Returns parent object. Read only.

**Obtained From**

Geocoder (LocateAddress, LocateAddressRaw)

**See Also**

Scripting Reference
**Geocoder Object**

Geocoding engine.

**Properties**

Application Application

Returns application. Read only.

Any Parent

Returns parent object. Read only.

**Methods**

GeocodeMatchSet LocateAddress(String address, String city, String state, String zip, Number offset)

Geocodes an address given by address, city, state and zip strings. Multiple matches are ordered from the most likely to least likely. Offset parameter is specified in meters and can be omitted.

GeocodeMatchSet LocateAddressRaw(String address, Number offset)

Geocodes an address given by an unparsed address string. Multiple matches are ordered from the most likely to least likely. Offset parameter is specified in meters and can be omitted.

Point LocateZip(Number zip)

Point LocateZip(String zip)

Returns a lat/lon centroid for a given zip code.

**Obtained From**

Application (NewGeocoder)

**See Also**

Scripting Reference
**Geom Object**
Geometric entity.

**Properties**

**Application**
Returns application. Read only.

**Number Area**
Returns area measured over an ellipsoid. Returned value is in square meters. Read only.

**Number AreaNative**
Returns area in native units. Read only.

**Rect Box**
Sets or returns bounding box. Modifying this property scales and shifts the entity. Read/write.

**BranchSet**
Sets or returns set of branches (can accept BranchSet, Branch, PointSet or Point when setting). Read/write.

**Point Center**
Sets or returns center of minimum enclosing circle. Modifying this property moves the entity. Read/write.

**Point CenterInner**
Returns inner centroid for areas. Read only.

**Point CenterWeight**
Returns center of weight for areas. Read only.

**Number Length**
Returns length or perimeter measured over an ellipsoid. Returned value is in meters. Read only.

**Number LengthNative**
Returns length or perimeter in native units. Read only.

**Any Parent**
Returns parent object. Read only.

**GeomType**
Returns type of entity. Read only.

**Methods**

**Geom Buffer**
Returns a buffer of given width.

**Boolean CheckContains**
Returns True if entity contains another entity and False otherwise.

**Boolean CheckIntersects**
Returns True if entity intersects another entity and False otherwise.
Boolean CheckNeighbors(Geom geom, Number epsilon)
Returns True if entity neighbors another entity and False otherwise.

Boolean CheckTouches(Geom geom, Number epsilon)
Returns True if entity touches another entity and False otherwise.

GeomSet Decompose(Number epsilon)
Returns set of primitive parts composing geometric entity.

GeomSet DecomposeToConvexParts
Returns set of convex parts composing area.

GeomSet DecomposeToTriangles()
Returns set of triangles composing an area.

TriangleSet DecomposeToTrianglesAdv()
Returns set of triangles composing an area as a set of triplets identifying vertices for each triangle.

Number DistanceNative(Geom geom, Number epsilon)
Returns distance to given entity.

Number Distance(Geom geom, Number epsilon)
Returns distance to given entity in degrees or meters depending on whether or not the coordinate system of the entity is lat/lon or not.

Number DistanceToPoint(Point point)
Returns distance to given point.

Number EnclosingCircle(Point point)
Returns radius of minimum enclosing circle and puts center of this circle into supplied parameter.

Geom EnclosingRect()
Returns minimum enclosing rectangle.

Geom Intersect(GeomSet geomSet, Number epsilon)
Returns a copy of an entity intersected with given set of entities.

Geom Normalize (Number epsilon)
Returns a copy of an entity with normalized metric.

Point ProjectPoint(Point point)
Returns the location on the geom that is closest to given point.

Geom Segmentize(Number length)
Returns a copy of an entity with no segment longer than specified value.

GeomSet SplitWithLines(GeomSet geomSet, Number epsilon)
Returns set of geometric entities composed from subject entity by splitting it with given set of lines.

Geom Subtract(GeomSet geomSet, Number epsilon)
Returns a copy of an entity minus given set of entities.

Object ToBinary()
Creates a binary representation of a geom in Geometry format.

Object ToBinarySDE(Number shiftX, Number shiftY, Number scale)

Creates a binary representation of a geom in Geometry (SDE) format. Shift and scale parameters specify conversion factors to integer coordinates and are optional. If omitted, shiftX is set to 0, shiftY is set to 0, and scale is set to 1.

Object ToBinarySHP()

Creates a binary representation of a geom in Geometry (SHP) format.

Object ToBinaryWKB()

Creates a binary representation of a geom in Geometry (WKB) format.

String ToTextWKT()

Creates a textual representation of a geom in OGC WKT format.

Obtained From

Application (NewGeom)

Geom (Buffer, EnclosingRect, Intersect, Normalize, Segmentize, Subtract)
GeomSet (ConvexHull, EnclosingRect, FarthestPair, Item, LastAdded, ShapeHull, Union)
Object (Geom)

Notes

It is possible to make a Geom object created using a script invalid, as long as the object does not represent the metric of any real drawing object or label. For example, it is possible to delete the last point in a branch or delete the last branch of such a Geom object. This corrects the strange situation that was possible in releases before 6.50 SP1 when a standalone Geom object was invalid at creation time, but could no longer become invalid after it has been made valid.

See Also

Scripting Reference
**GeomSet Object**
Set of geometric entities.

**Properties**

Application Application
Returns application. Read only.

Rect Box
Sets or returns bounding box. Modifying this property scales and shifts the set. Read/write.

Point Center
Sets or returns center of the centroid of the set. Modifying this property moves the set. Read/write.

Number Count
Returns number of entities in set. Read only.

Geom Item(Number index)
Returns entity with given index. Read only.

Geom LastAdded
Returns last added entity if any. Read only.

Any Parent
Returns parent object. Read only.

**Methods**

Add(Geom geom)
Append entity to set.

GeomSet BoundedAreas(Number epsilon)
Returns areas bounded by a set of lines.

GeomSet Cluster(Number factor)
Returns lines connecting clusters of a set of points.

GeomSet ClusterZahn(Number factor)
Returns lines connecting Zahn clusters of a set of points.

GeomSet ConstrainedTriangulationEdges(Number epsilon)
Returns edges (line objects) of constrained Delaunay triangulation of a set of objects.

GeomSet ConstrainedTriangulationTiles(Number epsilon)
Returns tiles (area objects) of constrained Delaunay triangulation of a set of objects.

Geom ConvexHull(Number epsilon)
Returns convex hull of a set.

GeomSet DistanceNetwork(Number distance)
Returns lines connecting pairs of points from subject set that are closer to each other than given distance.
Number EnclosingCircle(Point center)
Returns radius of minimum enclosing circle and puts center of this circle into supplied parameter.

Geom EnclosingRect()
Returns minimum enclosing rectangle.

GeomSet FarthestNeighbor(GeomSet geomSet, Number epsilon)
Returns set of lines connecting points from subject set and their farthest neighbors from given set.

GeomSet FarthestNeighborSymm(GeomSet geomSet, Number epsilon)
Returns set of lines connecting points from subject set and their symmetric farthest neighbors from given set.

Geom FarthestPair(Number epsilon)
Returns line between farthest pair of points in a point set.

GeomSet GabrielNetwork()
Returns lines connecting Gabriel network of a set of points.

GeomSet IntersectLines(Number epsilon)
Returns a copy of set with resolved line intersections.

GeomSet IntersectionPoints(Number epsilon)
Returns all intersections of a set of lines.

GeomSet JoinLines(Number epsilon)
Returns a copy of set joining lines.

GeomSet NearestNeighbor(GeomSet geomSet, Number epsilon)
Returns set of lines connecting points from subject set and their nearest neighbors from given set.

GeomSet NearestNeighborSymm(GeomSet geomSet, Number epsilon)
Returns set of lines connecting points from subject set and their symmetric nearest neighbors from given set.

Geom NearestPair(Number epsilon)
Returns line between nearest pair of points in a point set.

GeomSet NormalizeTopology(Number epsilon)
Returns a copy of a set with normalized topological relations.

GeomSet RelativeNeighborhoodNetwork()
Returns lines connecting relative neighborhood network of a set of points.

Remove(Number index)
Remove entity with given index.

RemoveAll()
Removes all entities.

Geom ShapeHull(Number cells, Number epsilon)
Returns shape hull of a set computed over a grid with given number of cells along the shortest axis.

GeomSet SpanningTree()
Returns lines connecting minimum spanning tree of a set of points.
GeomSet TriangulationEdges(Number epsilon)
Returns edges of Delaunay triangulation of a set of points.

GeomSet TriangulationTiles(Number epsilon)
Returns tiles of Delaunay triangulation of a set of points.

GeomSet VoronoiEdges(Number epsilon)
Returns edges of Voronoi diagram of a set of points.

GeomSet VoronoiTiles(Number epsilon)
Returns tiles of Voronoi diagram of a set of points.

GeomSet VoronoiVertices(Number epsilon)
Returns vertices of Voronoi diagram of a set of points.

Geom Union(Number epsilon)
Returns a union of all areas within set.

Obtained From
Geom (Decompose, DecomposeConvex, SplitWithLines)

Scripting Reference
**History Object**
History log.

**Properties**

- **Application Application**
  Returns application. Read only.

- **Any Parent**
  Returns parent object. Read only.

**Methods**

- **Log(String text, Boolean popup)**
  Append text to log. Popup parameter is optional. When it is set to True, history window automatically pops up on output.

**Obtained From**

- Application (History)

Scripting Reference
Image Object
Image component.

Properties

Application Application
Returns application. Read only.

Color BackgroundColor
Sets or returns background color. Read / write.

Rect Box
Returns bounding box of all pixels. Read only.

Boolean Cached
Sets or returns caching option for shared component in Enterprise Edition. Read/write.

Number Channels
Return number of image channels. Read only.

ControlPointSet ControlPointSet
Returns set of control points. Read only.

CoordinateSystem CoordinateSystem
Sets or returns coordinate system. Read/write.

Boolean CoordinateSystemVerified
Checks whether or not the component coordinate system has been verified by the user, or alters the verification state. Read / write.

View DefaultView
Returns default view. Read only.

String Description
Sets or returns component description. Read/write.

Document Document
Returns owner document. Read only.

Folder Folder
Sets or returns containing folder. Read/write.

Number Height
Returns image height in pixels. Read only.

Number ID
Returns unique component ID. Read only.

Boolean IsCheckedOut
Checks if component is shared and checked out in Enterprise Edition. Read only.

Boolean IsCheckedOutRemotely
Checks if component is shared and checked out by another user in Enterprise Edition. Read only.
Boolean IsLinked()
  Returns True if image is linked and False otherwise.

Boolean IsModified
  Checks if component is modified since last save in Enterprise Edition. Read only.

Boolean IsOutdated
  Checks if component is shared and there is a later version of the component on the Enterprise server in Enterprise Edition. Read only.

Boolean IsReadOnly
  Checks if component is readonly (eg, shared and not checked out) in Enterprise Edition. Read only.

Boolean IsShared
  Checks if component is shared on an Enterprise server in Enterprise Edition. Read only.

Boolean IsWritable
  Checks if component is writable in Enterprise Edition. Read only.

Number LineRest
  Returns number of bytes used to pad each image line. Read only.

Number LineSize
  Returns number of bytes used to store each image line. Read only.

String LinkRowset
  Returns the source rowset of a linked component. Read only.

String LinkSource
  Returns the data source of a linked component. Read only.

String LinkTechnology
  Returns the data access technology used by a linked component. Read only.

String Name
  Sets or returns component name. Read/write.

String Note
  Sets or returns notes associated with the component. Read/write.

ComponentSet OwnedComponentSet
  Returns set of components bound to this component. Read only.

ComponentSet OwnedLayoutSet
  Returns set of layouts bound to this component. Read only.

Palette OwnedPalette
  Returns palette bound to this component. Read only.

Component Owner
  Returns owner component if any. Read only.
Any Parent  
Returns parent object. Read only.

PixelSet PixelSet  
Returns set of image pixels. Read only.

Number RemoteVersion  
Returns version of shared component available on the Enterprise server in Enterprise Edition. Read only.

ImageSelectionSet SavedSelectionSet  
Returns set of saved selections. Read only.

PixelSet Selection  
Returns set of selected pixels. Read only.

String Server  
Returns server identification string for shared component in Enterprise Edition. Read only.

String ShareStatus  
Returns textual report on component sharing status in Enterprise Edition. Read only.

ComponentType Type  
Returns component type. Read only.

String TypeName  
Returns textual representation of the component type. Read only.

Unlink()  
Unlinks component. If the component is not linked, does nothing.

Number Version  
Returns version of shared component within the local project in Enterprise Edition. Read only.

ViewSet ViewSet  
Returns set of views associated with this component. Read only.

Number Width  
Returns image width in pixels. Read only.

Number ZoomMax  
Sets or returns maximum zoom level. Read/write.

Number ZoomMin  
Sets or returns minimum zoom level. Read/write.

Methods

CheckIn()  
Checks in changes made to a shared component to the Enterprise server in Enterprise Edition.

CheckOut()  
Checks out a shared component for editing in Enterprise Edition.
Clear(Boolean selection)
Clears entire component or selection within the component. Calling the method without parameters clears entire component.

Copy(Boolean selection)
Copies entire component or selection within the component into the Clipboard. Calling the method without parameters copies entire component.

CopyBitmap(Boolean selection)
Copies entire component or selection within the component into the Clipboard as a bitmap. Calling the method without parameters copies entire component.

Cut(Boolean selection)
Copies entire component or selection within the component into the Clipboard and then clears it. Calling the method without parameters cuts entire component.

CutBitmap(Boolean selection)
Copies entire component or selection within the component into the Clipboard as a bitmap and then clears it. Calling the method without parameters cuts entire component.

GetLatestVersion()
Gets the latest version of a shared component from the Enterprise server in Enterprise Edition.

Boolean IsAlpha()
Returns True if image is RGBA and False otherwise.

Boolean IsColor()
Returns True if image is RGB and False otherwise.

Boolean IsCompressed()
Returns True if image is compressed and False otherwise.

Boolean IsDatabase()
Returns True if image is linked from a database and False otherwise.

Boolean IsLibrary()
Returns True if image is an image library and False otherwise. Read only.

Boolean IsManifold()
Returns True if image is linked from a Manifold Image Server and False otherwise.

Boolean IsMono()
Returns True if image is grayscale and False otherwise.

Boolean IsOGC()
Returns True if image is linked from an OGC WMS server and False otherwise.

Boolean IsPalette()
Returns True if image is palette and False otherwise.

Boolean IsTerraServer()
Returns True if image is linked from TerraServer and False otherwise.

Open()
Opens component.

OpenInNewWindow()
Opens component in new window.

Paste(Boolean replace)
Pastes the contents of the Clipboard into the component replacing current selection or leaving it intact. Calling the method without parameters replaces selection.

Print(Boolean useDialog)
Prints component.

ProjectTo(CoordinateSystem system, Boolean adjustResolution)
Projects component to another coordinate system. If the second parameter is True or omitted, the system automatically adjusts the local scale parameters of the coordinate system to match the current resolution of the image.

RenderAreaTo(String name, Number width, Number height, Rect area, Boolean clean)
Renders component area into an image with given name, width and height. If last parameter is True, legend, north arrow and scale bar are not rendered even if they are on.

RenderTo(String name, Number width, Number height, Boolean clean)
Render component into an image with given name, width and height. If last parameter is True, legend, north arrow and scale bar are not rendered even if they are turned on.

SelectAll()
Selects all pixels.

SelectInverse()
Selects pixels that were not selected and vice versa.

SelectNone()
Unselects all pixels.

UndoCheckOut()
Undoes changes made to a shared component and gets the latest version of the component from the Enterprise server in Enterprise Edition.

Obtained From
Document (NewImage)

Scripting Reference
**ImageSelectionSet Object**
Set of saved selections within image.

**Properties**

- **Application Application**
  Returns application. Read only.

- **Number Count**
  Returns number of selections in set. Read only.

- **PixelSet Item(Number index)**
  Returns selection with given index. Read only.

- **Any Parent**
  Returns parent object. Read only.

**Methods**

- **Number ItemByMask(Number mask)**
  Returns index of selection with given mask value or -1.

- **Number ItemByName(String name)**
  Returns index of selection with given name or -1.

**Obtained From**

- **Image (SavedSelectionSet)**

Scripting Reference
Import Object
Generic importer.

Properties

Application Application
Returns application. Read only.

ComponentSet ComponentSet
Returns set of components created by the import. Read only.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string (eg. "Text Files (*.txt)"). Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of import properties. Read only.

Methods

Boolean CanImport(ComponentType type)
Returns True if importer can read components of given type and False otherwise.

Import(String fileName, ConvertPrompt prompt)
Imports given file.

Obtained From

Application (NewImport)

Scripting Reference
ImportAdf Object
ADF importer.

Properties

Application Application
Returns application. Read only.

ConverterItemSet Columns
Returns set of import columns (vector data only). Read only.

ComponentSet ComponentSet
Returns set of components created by the import. Read only.

ConvertPolicy ConvertPolicy
Sets or returns column import policy (vector data only). Read/write.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

Boolean ImportAreas
Sets or returns area composition option (vector data) or area import option (TINs). Read/write.

Boolean ImportPoints
Sets or returns point import option (TINs only). Read/write.

Boolean ImportSurface
Sets or returns surface import option (TINs only). Read/write.

Boolean ImportTicks
Sets or returns tick import option (vector data only). Read/write.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of import properties. Read only.

Number SurfaceHeight
Sets or returns surface height (TINs only). Read/write.

Number SurfaceWidth
Sets or returns surface width (TINs only). Read/write.

Methods
Boolean CanImport(ComponentType type)
Returns True if importer can read components of given type and False otherwise.

Import(String fileName, ConvertPrompt prompt)
Imports given file.

Obtained From

Application (NewImport("ADF"))

Returns set of import columns. Read only.

ComponentSet ComponentSet
Returns set of components created by the import. Read only.

String ConnectionString
Sets or returns connection string. Read/write.

ConvertPolicy ConvertPolicy
Sets or returns table import policy. Read/write.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of import properties. Read only.

Methods

String BuildConnectionString(String server, String login, String password)
Composes a connection string for Oracle ADO.NET provider. The last two arguments are optional.

Boolean CanImport(ComponentType type)
Returns True if importer can read components of given type and False otherwise.

Import(String table, ConvertPrompt prompt)
Imports table from the data source specified by the connection string.

Obtained From

Application (NewImport("ADO.NET Oracle"))

**Boolean CanImport(ComponentType type)**

Returns True if importer can read components of given type and False otherwise.

**Import(String fileName, ConvertPrompt prompt)**

Imports given file.

**Obtained From**

Application (NewImport("BMP"))

**See Also**

Scripting Reference
ImportBna Object
BNA importer.

Properties

Application Application
Returns application. Read only.

ConverterItemSet Columns
Returns set of import columns. Read only.

ComponentSet ComponentSet
Returns set of components created by the import. Read only.

ConvertPolicy ConvertPolicy
Sets or returns column import policy. Read/write.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of import properties. Read only.

Methods

Boolean CanImport(ComponentType type)
Returns True if importer can read components of given type and False otherwise.

Import(String fileName, ConvertPrompt prompt)
Imports given file.

Obtained From

Application (NewImport("BNA"))

**ImportCadrgCib Object**

CADRG/CIB importer.

**Properties**

- **Application**
  Returns application. Read only.

- **ComponentSet**
  Returns set of components created by the import. Read only.

- **ConvertPolicy**
  Sets or returns module import policy. Read/write.

- **DefaultExtension**
  Returns default file extension. Read only.

- **Filter**
  Returns filter string. Read only.

- **Modules**
  Returns set of import modules. Read only.

- **Name**
  Returns file format name. Read only.

- **Parent**
  Returns parent object. Read only.

- **PropertySet**
  Returns set of import properties. Read only.

**Methods**

- **CanImport(ComponentType type)**
  Returns True if importer can read components of given type and False otherwise.

- **Import(String fileName, ConvertPrompt prompt)**
  Imports given file.

**Obtained From**

- Application (NewImport("CADRG / CIB"))

Scripting Reference
ImportCeosSeaWifs Object
CEOS SeaWiFS importer.

Properties

Application Application
Returns application. Read only.

ComponentSet ComponentSet
Returns set of components created by the import. Read only.

ConvertPolicy ConvertPolicy
Sets or returns module import policy. Read/write.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

ConverterItemSet Modules
Returns set of import modules. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of import properties. Read only.

Methods

Boolean CanImport(ComponentType type)
Returns True if importer can read components of given type and False otherwise.

Import(String fileName, ConvertPrompt prompt)
Imports given file.

Obtained From

Application (NewImport("CEOS SeaWiFS"))

See Also

Scripting Reference
ImportCsv Object
CSV importer.

Properties

Application Application
Returns application. Read only.

Boolean ColumnHeaderLine
Sets or returns column header line option. If True, the first line in the imported file contains column names. Read/write.

ConverterItemSet Columns
Returns set of import columns. Read only.

ComponentSet ComponentSet
Returns set of components created by the import. Read only.

String ConnectionString
Sets or returns connection string (path to a file). Read/write.

ConvertPolicy ConvertPolicy
Sets or returns column import policy. Read/write.

String DefaultExtension
Returns default file extension. Read only.

String Delimiter
Sets or returns the list delimiter character. Read/write.

String DelimiterDecimal
Sets or returns the decimal delimiter character. Read/write.

String Filter
Returns filter string. Read only.

Boolean ForceAnsiCharset
Sets or returns force ANSI character set option. If True, the import uses the default ANSI character set. If False, the import uses the default OEM character set. Read/write.

Boolean ForceText
Sets or returns force text types option. If True, all columns are imported as text. If False, the system determines the type of each column from the first few lines of the imported file. Read/write.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of import properties. Read only.
Number ScanLines
Sets or returns the number of lines to scan to determine column types. Has no effect if the ForceText property is set to True. Read/write.

String TextQualifier
Sets or returns the text qualifier character. Read/write.

Methods

Boolean CanImport(ComponentType type)
Returns True if importer can read components of given type and False otherwise.

Import(String table, ConvertPrompt prompt)
Imports table from the data source specified by the connection string.

Obtained From

Application (NewImport("CSV"))

ImportDb2 Object
Native DB2 import.

Properties

Application Application
Returns application. Read only.

ConverterItemSet Columns
Returns set of import columns. Read only.

ComponentSet ComponentSet
Returns set of components created by the import. Read only.

String ConnectionString
Sets or returns connection string. Read/write.

ConvertPolicy ConvertPolicy
Sets or returns table import policy. Read/write.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of import properties. Read only.

Methods

String BuildConnectionString(String server, String login, String password)
Composes a connection string for DB2 native client. The last two arguments are optional.

Boolean CanImport(ComponentType type)
Returns True if importer can read components of given type and False otherwise.

Import(String table, ConvertPrompt prompt)
Imports table from the data source specified by the connection string.

Obtained From

Application (NewImport("DB2"))

Scripting Reference
ImportGrdSurfer Object
Surfer GRD importer (imports Surfer 6 GRD, Surfer 7 GRD and Surfer ASCII GRD formats).

Properties

Application Application
Returns application. Read only.

ComponentSet ComponentSet
Returns set of components created by the import. Read only.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of import properties. Read only.

Methods

Boolean CanImport((ComponentType type)
Returns True if importer can read components of given type and False otherwise.

Import(String fileName, ConvertPrompt prompt)
Imports given file.

Obtained From

Application (NewImport("Surfer GRD"))

Scripting Reference
ImportOracle Object
Native Oracle import.

Properties

Application Application
- Returns application. Read only.

ConverterItemSet Columns
- Returns set of import columns. Read only.

ComponentSet ComponentSet
- Returns set of components created by the import. Read only.

String ConnectionString
- Sets or returns connection string. Read/write.

ConvertPolicy ConvertPolicy
- Sets or returns table import policy. Read/write.

String DefaultExtension
- Returns default file extension. Read only.

String Filter
- Returns filter string. Read only.

String Name
- Returns file format name. Read only.

Any Parent
- Returns parent object. Read only.

ConverterPropertySet PropertySet
- Returns set of import properties. Read only.

Methods

String BuildConnectionString(String server, String login, String password)
- Composes a connection string for Oracle native client. The last two arguments are optional.

Boolean CanImport(ComponentType type)
- Returns True if importer can read components of given type and False otherwise.

Import(String table, ConvertPrompt prompt)
- Imports table from the data source specified by the connection string.

Obtained From

Application (NewImport("Oracle"))

Returns filter string. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of import properties. Read only.

**Methods**

Boolean CanImport(ComponentType type)
Returns True if importer can read components of given type and False otherwise.

Import(String fileName, ConvertPrompt prompt)
Imports given file.

**Obtained From**

Application (NewImport("IDRISI IMG"))

**See Also**

Scripting Reference
ImportS57 Object
S-57 importer.

Properties

Application Application
Returns application. Read only.

ComponentSet ComponentSet
Returns set of components created by the import. Read only.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of import properties. Read only.

Methods

Boolean CanImport(ComponentType type)
Returns True if importer can read components of given type and False otherwise.

Import(String fileName, ConvertPrompt prompt)
Imports given file.

Obtained From

Application (NewImport("S-57"))

SDTS importer.

**Properties**

Application Application
Returns application. Read only.

ComponentSet ComponentSet
Returns set of components created by the import. Read only.

ConvertPolicy ConvertPolicy
Sets or returns column import policy. Read/write.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

Boolean ImportDataDefScheme
Sets or returns data definition scheme import option. Read/write.

Boolean ImportZ
Sets or returns height import option. Read/write.

Boolean MapColumns
Sets or returns column mapping option. Read/write.

ConverterItemSet Modules
Returns set of import modules. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

ConverterPropertySet PropertySet
Returns set of import properties. Read only.

**Methods**

Boolean CanImport(ComponentType type)
Returns True if importer can read components of given type and False otherwise.

Import(String fileName, ConvertPrompt prompt)
Imports given file.

SHP importer.

**Properties**

Application Application

Returns application. Read only.

ConverterItemSet Columns

Returns set of import columns. Read only.

ComponentSet ComponentSet

Returns set of components created by the import. Read only.

ConvertPolicy ConvertPolicy

Sets or returns column import policy. Read/write.

String DefaultExtension

Returns default file extension. Read only.

String Filter

Returns filter string. Read only.

Boolean ImportM

Sets or returns measure import option. Read/write.

Boolean ImportZ

Sets or returns height import option. Read/write.

String Name

Returns file format name. Read only.

Any Parent

Returns parent object. Read only.

ConverterPropertySet PropertySet

Returns set of import properties. Read only.

**Methods**

Boolean CanImport(ComponentType type)

Returns True if importer can read components of given type and False otherwise.

Import(String fileName, ConvertPrompt prompt)

Imports given file.

**Obtained From**

Application (NewImport("SHP"))

ImportSid Object
SID importer.

Properties

Application Application
Returns application. Read only.

ComponentSet ComponentSet
Returns set of components created by the import. Read only.

String DefaultExtension
Returns default file extension. Read only.

String Filter
Returns filter string. Read only.

String Name
Returns file format name. Read only.

Any Parent
Returns parent object. Read only.

String Password
Sets or returns password for a password-protected file. Read/write.

ConverterPropertySet PropertySet
Returns set of import properties. Read only.

Number Scale
Sets or returns scale reduction factor. Read/write.

Methods

Boolean CanImport(ComponentType type)
Returns True if importer can read components of given type and False otherwise.

Import(String fileName, ConvertPrompt prompt)
Imports given file.

Obtained From

Application (NewImport("SID"))

Label Object

Label.

Properties

Application Application
Returns application. Read only.

Color BackColor
Sets or returns background color. Read/write.

Boolean Bold
Returns True if the label font is bold and False otherwise, or modifies the font. Read/write.

Color BorderForeColor
Sets or returns border foreground color. Read/write.

Number CharSet
Sets or returns the character set used by the label font. Read/write.

String FontFace
Sets or returns the facename of the label font. Read/write.

Color ForeColor
Sets or returns foreground color. Read/write.

Geom Geom
Sets or returns label metric. Read/write.

Number ID
Returns unique label ID. Read only.

Boolean Italic
Returns True if the label font is italic and False otherwise, or modifies the font. Read/write.

LabelAlignMulti LabelAlignMulti
Sets or returns multiline label alignment. Read/write.

LabelAlignX LabelAlignX
Sets or returns horizontal label alignment. Read/write.

LabelAlignY LabelAlignY
Sets or returns vertical label alignment. Read/write.

Object Link
Returns owner object. Read only.

Number Mask
Sets or returns label mask. Read/write.

Component OwnerComponent
Returns labels component containing this label. Read only.
Any Parent
Returns parent object. Read only.

Number Rotation
Sets or returns label rotation in degrees. Read/write.

Boolean Selected
Selects or deselects label or checks if label is selected. Read/write.

Number Size
Sets or returns label text size in points. Read/write.

Boolean StrikeOut
Returns True if the label font is struck out and False otherwise, or modifies the font. Read/write.

Number Style
Sets or returns label style. Read/write.

String Text
Sets or returns label text. Read/write.

Boolean Underline
Returns True if the label font is underlined and False otherwise, or modifies the font. Read/write.

Boolean UsesCustomFormat
Returns True if the label uses custom format and False otherwise. Read only.

Methods

Boolean IsLine()
Returns True if label is aligned to line and False otherwise.

Boolean IsLinked()
Returns True if label if linked to object and False otherwise.

Boolean IsMasked(Number mask)
Returns True if label has given mask or masks and False otherwise.

Boolean IsPoint()
Returns True if label is aligned to point and False otherwise.

Boolean IsSelected()
Returns True if label is selected and False otherwise. This method is deprecated. Use the Selected property instead.

ResetFormat()
Resets label format to the default values.

Obtained From

EventArgs (Label)
LabelSet (Item, LastAdded)
LabelWindow (ActiveLabel)
MapWindow (ActiveLabel)

Scripting Reference
**Labels Object**
Labels component.

**Properties**

Application
Returns application. Read only.

BackgroundColor
Sets or returns background color. Read / write.

Boolean Bold
Returns True if component font is bold and False otherwise, or modifies the font. Read/write.

Rect Box
Returns bounding box of all labels. Read only.

Boolean Cached
Sets or returns caching option for shared component in Enterprise Edition. Read/write.

Number CalloutDistance
Sets or returns minimal length of a callout line, in points. Read/write.

Boolean Callouts
Returns True if the system displays a callout line for each point label and False otherwise, or turns callout lines on or off. Read/write.

Number CharSet
Sets or returns the character set used by component font. Read/write.

ControlPointSet
Returns set of control points. Read only.

CoordinateSystem
Sets or returns coordinate system. Read/write.

Boolean CoordinateSystemVerified
Checks whether or not the component coordinate system has been verified by the user, or alters the verification state. Read / write.

View
Returns default view. Read only.

String Description
Sets or returns component description. Read/write.

Document
Returns owner document. Read only.

Folder
Sets or returns containing folder. Read/write.

String FontFace
Sets or returns the facename of the component font. Read/write.

Number ID
Returns unique component ID. Read only.

Boolean IsCheckedOut
Checks if component is shared and checked out in Enterprise Edition. Read only.

Boolean IsCheckedOutRemotely
Checks if component is shared and checked out by another user in Enterprise Edition. Read only.

Boolean IsModified
Checks if component is modified since last save in Enterprise Edition. Read only.

Boolean IsOutdated
Checks if component is shared and there is a later version of the component on the Enterprise server in Enterprise Edition. Read only.

Boolean IsReadOnly
Checks if component is readonly (eg, shared and not checked out) in Enterprise Edition. Read only.

Boolean IsShared
Checks if component is shared on an Enterprise server in Enterprise Edition. Read only.

Boolean IsWritable
Checks if component is writable in Enterprise Edition. Read only.

Boolean Italic
Returns True if component font is italic and False otherwise, or modifies the font. Read/write.

LabelAlignMulti
Sets or returns alignment of multiline labels. Read/write.

LabelAlignX
Sets or returns horizontal label alignment. Read/write.

LabelAlignY
Sets or returns vertical label alignment. Read/write.

Format LabelBackground
Returns background color used for labels. Read only.

Format LabelBorder
Returns border color used for labels. Read only.

Boolean LabelEachBranch
Returns True if each label bound to a line outputs text near each branch of the line and False otherwise, or sets the output mode. Read/write.

Format LabelForeground
Returns foreground color used for labels. Read only.

Format LabelRotation
Returns rotation used for labels. Read only.

LabelSet LabelSet
Returns set of labels. Read only.

Format LabelSize
Returns size used for labels. Read only.

Format LabelStyle
Returns style used for labels. Read only.

Boolean LeftToRight
Returns True if each label bound to a line is automatically oriented left-to-right and False otherwise, or sets the orientation. Read/write.

Number LineCharacterSpacing
Sets or returns line character spacing, in points. Read/write.

Number LineInteriorSpacing
Sets or returns spacing between labels on the same line, in points. Read/write.

Number LineOffset
Sets or returns line offset, in points. Read/write.

Boolean MultipleLabelsPerBranch
Returns True if the system places multiple labels along a line and False otherwise, or modifies this behavior. Read/write.

String Name
Sets or returns component name. Read/write.

String Note
Sets or returns notes associated with the component. Read/write.

Boolean OptimizeLabelAlignX
Returns True if the system optimizes horizontal alignment for point labels and False otherwise, or allows or disallows optimization. Read/write.

Boolean OptimizeLabelAlignY
Returns True if the system optimizes vertical alignment for point labels and False otherwise, or allows or disallows optimization. Read/write.

ComponentSet OwnedComponentSet
Returns set of components bound to this component. Read only.

ComponentSet OwnedLayoutSet
Returns set of layouts bound to this component. Read only.

Component Owner
Returns owner component if any. Read only.

Any Parent
Returns parent object. Read only.
Boolean PerLabelFormat
Returns True if per-label format is enabled and False otherwise, or enables/disables per-label format. Read/write.

Number PointOffsetX
Sets or returns point offset by X, in points. Read/write.

Number PointOffsetY
Sets or returns point offset by Y, in points. Read/write.

Boolean ReduceShortLinesToPoints
Returns True if the system renders labels bound to lines that are too short to fit label text as though the labels were bound to the center of the first line branch and False otherwise, or modifies this behavior. Read / write.

Number RemoteVersion
Returns version of shared component available on the Enterprise server in Enterprise Edition. Read only.

Boolean ResolveOverlaps
Returns True if labels overlapping other labels are not displayed and False otherwise, or sets the overlap control mode. Read/write.

LabelSelectionSet SavedSelectionSet
Returns set of saved selections. Read only.

LabelSet Selection
Returns set of selected labels. Read only.

String Server
Returns server identification string for shared component in Enterprise Edition. Read only.

String ShareStatus
Returns textual report on component sharing status in Enterprise Edition. Read only.

Number Spacing
Sets or returns spacing between labels, in points. Read/write.

Boolean StrikeOut
Returns True if component font is striked out and False otherwise, or modifies the font. Read/write.

Boolean Synchronized
Returns True if the component automatically creates a new label for each new drawing object and False otherwise, or modifies this behavior, for a labels component bound to a drawing. Read/write.

Text Text
Sets or returns label text for label components bound to drawings. Read/write.

ComponentType Type
Returns component type. Read only.

String TypeName
Returns textual representation of the component type. Read only.

Boolean Underline
Returns True if component font is underlined and False otherwise, or modifies the font. Read/write.
Number Version
Returns version of shared component within the local project in Enterprise Edition. Read only.

ViewSet ViewSet
Returns set of views associated with this component. Read only.

Number ZoomMax
Sets or returns maximum zoom level. Read/write.

Number ZoomMin
Sets or returns minimum zoom level. Read/write.

Number ZoomRender
Sets or returns render zoom level. Read/write.

Methods

CheckIn()
Checks in changes made to a shared component to the Enterprise server in Enterprise Edition.

CheckOut()
Checks out a shared component for editing in Enterprise Edition.

Clear(Boolean selection)
Clears entire component or selection within the component. Calling the method without parameters clears entire component.

Copy(Boolean selection)
Copies entire component or selection within the component into the Clipboard. Calling the method without parameters copies entire component.

Cut(Boolean selection)
Copies entire component or selection within the component into the Clipboard and then clears it. Calling the method without parameters cuts entire component.

GetLatestVersion()
Gets the latest version of a shared component from the Enterprise server in Enterprise Edition.

Boolean isEmpty()
Returns True if component contains no labels and False otherwise.

Open()
Opens component.

OpenInNewWindow()
Opens component in new window.

Paste(Boolean replace)
Pastes the contents of the Clipboard into the component replacing current selection or leaving it intact. Calling the method without parameters replaces selection.

Print(Boolean useDialog)
Prints component.

ProjectTo(CoordinateSystem system)
Projects component to another coordinate system.

RenderAreaTo(String name, Number width, Number height, Rect area, Boolean clean)
Renders component area into an image with given name, width and height. If last parameter is True, legend, north arrow and scale bar are not rendered even if they are on.

RenderTo(String name, Number width, Number height, Boolean clean)
Render component into an image with given name, width and height. If last parameter is True, legend, north arrow and scale bar are not rendered even if they are turned on.

SelectAll()
Selects all labels.

SelectInverse()
Selects labels that were not selected and vice versa.

SelectNone()
Unselects all labels.

UndoCheckOut()
Undoes changes made to a shared component and gets the latest version of the component from the Enterprise server in Enterprise Edition.

Obtained From
Document (NewLabels)

LabelSelectionSet Object
Set of saves selections within labels.

Properties

Application Application
Returns application. Read only.

Number Count
Returns number of selections in set. Read only.

LabelSet Item(Number index)
Returns selection with given index. Read only.

Any Parent
Returns parent object. Read only.

Methods

Number ItemByMask(Number mask)
Returns index of selection with given mask value or -1.

Number ItemByName(String name)
Returns index of selection with given name or -1.

Obtained From

Labels (SavedSelectionSet)

See Also

Scripting Reference
LabelSet Object
Set of labels.

Properties

Application Application
Returns application. Read only.

Rect Box
Returns bounding box of all labels in set. Read only.

Number Count
Returns number of labels in set. Read only.

Label Item(Number index)
Returns label with given index. Read only.

Label LastAdded
Returns last added label if any. Read only.

Number Mask
Returns mask value. Read only.

String Name
Returns name of set. Read only.

Component OwnerComponent
Returns labels component containing this set. Read only.

Any Parent
Returns parent object. Read only.

Methods

Add(String text, Branch branch)
Add(String text, BranchSet branchSet)
Add(String text, Geom geom)
Add(String text, Point point)
Add(String text, PointSet pointSet)
Appends label to label set of stand-alone labels component.

Add(Object object, Branch branch)
Add(Object object, BranchSet branchSet)
Add(Object object, Geom geom)
Add(Object object, Point point)
Add(Object object, PointSet pointSet)
Appends label to label set of labels component bound to drawing.

Boolean IsSystem()
Returns True if label set is system and False otherwise.

Number ItemByID(Number id)
Returns index of label with given ID or -1.

Remove(Number index)
Removes label with given index.

RemoveAll()
Removes all labels.

Obtained From

Labels (LabelSet, Selection)
LabelSelectionSet (Item)

See Also

Scripting Reference
LabelWindow Object
Labels window.

Properties

Component ActiveComponent
Returns labels component shown in window. Read only.

Label ActiveLabel
Returns label selected for editing. Read only.

Application Application
Returns application. Read only.

Rect Bounds
Returns the area covered by the window, in the coordinate system of the displayed component. Read only.

Component Component
Returns labels component shown in window. Read only.

Number Height
Returns window height in pixels. Read only.

Point Location
Sets or returns viewport center. Read/write.

Point LocationLatLon
Sets or returns viewport center in lat/lon coordinates. Read/write.

Any Parent
Returns parent object. Read only.

Number Scale
Sets or returns viewport scale (projected components only). Read/write.

Number ScaleInternal
Sets or returns internal pixel-to-data ratio. Read/write.

Number Width
Returns window width in pixels. Read only.

Methods

Close()
Closes window.

Boolean HasActiveLabel()
Returns True if some label within the window is selected for editing and False otherwise.

Boolean HasLocation()
Returns True if viewport center can be modified and False otherwise.
Boolean HasScale()
Returns True if viewport scale can be obtained or modified and False otherwise.

Boolean HasScaleInternal()
Returns True.

MoveTo(Branch branch)
MoveTo(BranchSet branchSet)
MoveTo(Component component)
MoveTo(Geom geom)
MoveTo(Label label)
MoveTo(LabelSet labelSet)
MoveTo(Object object)
MoveTo(ObjectSet objectSet)
MoveTo(Pixel pixel)
MoveTo(PixelSet pixelSet)
MoveTo(Point point)
MoveTo(PointSet pointSet)
MoveTo(Rect rect)
Centers viewport on given object or set of objects. Branches, geoms, points, rects and their sets are assumed to be in the coordinate system of the displayed component.

MoveToLocation(Point point, Boolean latLon)
Centers viewport on given location. LatLon parameter is optional.

Refresh()
Updates window contents.

RenderTo(String name)
Renders window into an image with given name.

ZoomTo(Branch branch)
ZoomTo(BranchSet branchSet)
ZoomTo(Component component)
ZoomTo(Geom geom)
ZoomTo(Label label)
ZoomTo(LabelSet labelSet)
ZoomTo(Object object)
ZoomTo(ObjectSet objectSet)
ZoomTo(Pixel pixel)
ZoomTo(PixelSet pixelSet)
ZoomTo(Point point)
ZoomTo(PointSet pointSet)
ZoomTo(Rect rect)
Zooms to given object or set of objects. Branches, geoms, points, rects and their sets are assumed to be in the coordinate system of the displayed component. If the bounding box of the object is a point (for example, if the object is a point), centers viewport on given object.

 Obtained From

WindowSet (Item, ActiveWindow)

Scripting Reference
Layer Object
Map layer.

Properties

Application Application
Returns application. Read only.

Boolean Clickable
Sets or returns the "clickable" restriction of a layer. Read/write.

Component Component
Returns reference component. Read only.

Boolean Editable
Sets or returns the "editable" restriction of a layer. Read/write.

Number Order
Sets or returns layer position in the display stack, from 0 (the topmost layer) to the number of layers minus 1 (the bottommost layer). Read/write.

Number Opacity
Sets or returns layer opacity. Opacity is a value from 100 (opaque) to 0 (transparent). Read/write.

Component OwnerComponent
Returns map component containing this layer if any. Read only.

Any Parent
Returns parent object. Read only.

Boolean Selectable
Sets or returns the "selectable" restriction of a layer. Read/write.

Boolean Snappable
Sets or returns the "snappable" restriction of a layer. Read/write.

Boolean Visible
Sets or returns layer visibility state. Read/write.

Obtained From

Document (NewLayer)
LayerSet (Item, LastAdded)

See Also

Scripting Reference
LayerSet Object
Set of map layers.

Properties

Application Application
Returns application. Read only.

Number Count
Returns number of layers in set. Read only.

Layer Item(Number index)
Layer Item(String name)
Returns layer with given index or name. Read only.

Layer LastAdded
Returns last added layer if any. Read only.

Component OwnerComponent
Returns map component containing this set of layers if any. Read only.

Any Parent
Returns parent object. Read only.

Methods

Add(Layer layer, Number position)
Appends layer to layer set at given position. If the position argument is omitted, the layer is appended to the top of the display stack.

Number ItemByID(Number id)
Returns index of layer with given ID or -1.

Number ItemByName(String name)
Returns index of layer with given name or -1.

Remove(Number index)
Removes layer with given index.

Obtained From

Map (LayerSet)

Scripting Reference
**Layout Object**
Layout component.

**Properties**

*Application Application*
Returns application. Read only.

*Color BackgroundColor*
Sets or returns background color. Read / write.

*Boolean Cached*
Sets or returns caching option for shared component in Enterprise Edition. Read/write.

*String Description*
Sets or returns component description. Read/write.

*String DeviceName*
Printer name. Read only.

*String DevicePort*
Printer port name. Read only.

*Document Document*
Returns owner document. Read only.

*LayoutEntrySet EntrySet*
Set of layout entries. Read only.

*Folder Folder*
Sets or returns containing folder. Read/write.

*Number ID*
Returns unique component ID. Read only.

*Boolean IsCheckedOut*
Checks if component is shared and checked out in Enterprise Edition. Read only.

*Boolean IsCheckedOutRemotely*
Checks if component is shared and checked out by another user in Enterprise Edition. Read only.

*Boolean IsModified*
Checks if component is modified since last save in Enterprise Edition. Read only.

*Boolean IsOutdated*
Checks if component is shared and there is a later version of the component on the Enterprise server in Enterprise Edition. Read only.

*Boolean IsReadOnly*
Checks if component is readonly (eg, shared and not checked out) in Enterprise Edition. Read only.

*Boolean IsShared*
Checks if component is shared on an Enterprise server in Enterprise Edition. Read only.
Boolean IsWritable
Checks if component is writable in Enterprise Edition. Read only.

String Name
Sets or returns component name. Read/write.

String Note
Sets or returns notes associated with the component. Read/write.

ComponentSet OwnedComponentSet
Returns set of components bound to this component. Read only.

Component Owner
Returns owner component if any. Read only.

String PageFormat
Returns textual name of page format. Read only.

Number PageMarginBottom
Bottom print margin in points. Read only.

Number PageMarginLeft
Left print margin in points. Read only.

Number PageMarginRight
Right print margin in points. Read only.

Number PageMarginTop
Top page margin in points. Read only.

Number PageNonPrintableBottom
Bottom side of a non-printable area in points. Read only.

Number PageNonPrintableLeft
Left side of a non-printable area in points. Read only.

Number PageNonPrintableRight
Right side of a non-printable area in points. Read only.

Number PageNonPrintableTop
Top side of a non-printable area in points. Read only.

Number PageResolutionX
Horizontal page resolution in dots per inch (DPI). Read only.

Number PageResolutionY
Vertical page resolution in dots per inch (DPI). Read only.

Number PagesByX
Sets or returns number of pages by X axis. Read/write.

Number PagesByY
Sets or returns number of pages by Y axis. Read/write.

**Number PageSizeX**
Horizontal size of printable area less margins in points. Read only.

**Number PageSizeY**
Vertical size of printable area less margins in points. Read only.

**Any Parent**
Returns parent object. Read only.

**Number RemoteVersion**
Returns version of shared component available on the Enterprise server in Enterprise Edition. Read only.

**String Server**
Returns server identification string for shared component in Enterprise Edition. Read only.

**String ShareStatus**
Returns textual report on component sharing status in Enterprise Edition. Read only.

**ComponentType Type**
Returns component type. Read only.

**String TypeName**
Returns textual representation of the component type. Read only.

**Number Version**
Returns version of shared component within the local project in Enterprise Edition. Read only.

**Methods**

**CheckIn()**
Checks in changes made to a shared component to the Enterprise server in Enterprise Edition.

**CheckOut()**
Checks out a shared component for editing in Enterprise Edition.

**Clear(Boolean selection)**
Clears entire component or selection within the component. Calling the method without parameters clears entire component.

**Copy(Boolean selection)**
Copies entire component or selection within the component into the Clipboard. Calling the method without parameters copies entire component.

**Cut(Boolean selection)**
Copies entire component or selection within the component into the Clipboard and then clears it. Calling the method without parameters cuts entire component.

**GetLatestVersion()**
Gets the latest version of a shared component from the Enterprise server in Enterprise Edition.

**Boolean IsEmpty()**
Returns True if layout does not contain any printable objects and False otherwise.
Load(String template)
   Loads layout template with given name.

LoadFrom(String xml)
   Loads layout template from given XML string.

LoadFromFile(String path)
   Loads layout template from given XML file.

Open()
   Opens component.

OpenInNewWindow()
   Opens component in new window.

Paste(Boolean replace)
   Pastes the contents of the Clipboard into the component replacing current selection or leaving it intact. Calling
   the method without parameters replaces selection.

Print(Boolean useDialog)
   Prints component.

RenderTo(String name, Number dpi, Number page)
   Render specified page of a layout with given resolution into an image with given name. If page is omitted, the
   first page is rendered.

SaveToFile(String path)
   Saves layout template to given XML file.

String ToXML()
   Saves layout template to XML string.

UndoCheckOut()
   Undoes changes made to a shared component and gets the latest version of the component from the Enterprise
   server in Enterprise Edition.

Scripting Reference
LayoutEntry Object
Layout entry.

Properties

Application Application
Returns application. Read only.

Boolean AutoSelectColumns
Toggles between automatic and custom column selection mode for tables. Read/write.

LayoutState Background
Sets or returns background rendering option, can be set to LayoutStateCustom. Read/write.

Color BackgroundColor
Sets or returns background color for non-component entries. Read/write.

Color BackgroundCustomColor
Sets or returns background color for component entries. Used when Background property is set to LayoutStateCustom. Read/write.

LayoutBorder Border
Sets or returns border. Read/write.

Color BorderColor
Sets or returns border color. Read/write.

Boolean BorderDegMinSec
Sets or returns the use of a degree / minute / second format for border coordinates. Read/write.

Boolean BorderEachPage
Toggles between the use of a shared coordinate border or individual coordinate borders on each page. Read/write.

Font BorderFont
Sets or returns border font. Read/write.

Number BorderMargin
Sets or returns border margin in points. Read/write.

Boolean BorderOverlaps
Allows or disallows overlaps for border labels. Read/write.

Number BorderRounding
Sets or returns border rounding option. Read/write.

Number BorderStep
Sets or returns border interval. Read/write.

Unit BorderUnit
Sets or returns units used for border interval. Read/write.

Color Color
Sets or returns foreground color for non-component entries. Read/write.

Boolean ColumnHeaders
Toggles the use of column headers for table components. Read/write.

ColumnSet ColumnSet
Returns set of printed columns for a table component. Used when AutoSelectColumns property is set to False. Read only.

Component Component
Returns associated component. Read only.

LayoutState ControlPoints
Sets or returns control points rendering option for component entries. Read/write.

Font Font
Sets or returns font. Read/write.

LayoutState Graticule
Sets or returns graticule rendering option for component entries. Read/write.

LayoutState Grid
Sets or returns grid rendering option for component entries. Read/write.

Boolean GridLines
Toggles the use of grid lines for table components. Read/write.

Number ID
Returns unique entry ID. Read only.

LayoutState Legend
Sets or returns legend rendering option for component entries. Read/write.

Number Mask
Sets or returns entry mask. Read/write.

LayoutState NorthArrow
Sets or returns north arrow rendering option for component entries. Read/write.

LayoutEntry Owner
Returns owner entry. Used for legend, north arrow, scale bar and text entries. Read only.

Component OwnerComponent
Returns layout component containing this entry. Read only.

LayoutPaging Paging
Sets or returns layout paging mode. Read/write.

String PagingFilter
Sets or returns layout paging filter (eg, "1-5,8"). Read/write.

Any Parent
Returns parent object. Read only.
LayoutState ScaleBar
Sets or returns scale bar rendering option for component entries. Read/write.

LayoutScope Scope
Sets or returns scope for component entries. Read/write.

Rect ScopeArea
Sets or returns area covered by the entry. Setting an area for entries whose scope is different from LayoutScopeBox or LayoutScopeScale fails. Read/write.

Point ScopeCenter
Sets or returns center location of the entry. Setting a location for entries whose scope is different from LayoutScopeBox or LayoutScopeScale fails. Read/write.

String ScopeDetail
Sets or returns name of layer, saved selection or view for component entries. Read/write.

Number ScopeScale
Sets or returns absolute scale of the entry (10 means a scale of 1:10 and 0.5 means a scale of 2:1). Setting a scale for entries whose scope is different from LayoutScopeBox or LayoutScopeScale fails. Setting or getting a scale for entries whose components are in lat/lon fails. Read/write.

Number ScopeScaleInternal
Sets or returns internal scale of the entry in native coordinate system units per inch. Setting a scale for entries whose scope is different from LayoutScopeBox or LayoutScopeScale fails. Read/write.

Boolean Selected
Selects or deselects entry or checks if entry is selected. Read/write.

Boolean ShadeAlternateRows
Toggles the shading of alternate rows for table components. Read/write.

Number SizeX
Returns horizontal size of entry in points. Read only.

Number SizeY
Returns vertical size of entry in points. Read only.

String Text
Sets or returns text of a text entry. Read/write.

LabelAlignMulti TextAlignMulti
Sets or returns multiline alignment of a text entry. Read/write.

LabelAlignX TextAlignX
Sets or returns horizontal alignment of a text entry. Read/write.

LabelAlignY TextAlignY
Sets or returns vertical alignment of a text entry. Read/write.

Number TextDecimals
Sets or returns number of decimal points to use for a text entry. Read/write.
LayoutType

Returns entry type. Read only.

Number X

Returns left entry coordinate in points. Read only.

Number Y

Returns top entry coordinate in points. Read only.

Number ZOrder

Returns entry Z order. Read only.

**Methods**

Boolean HasOwner

Returns True if entry has an owner and False otherwise.

Boolean IsMasked(Number mask)

Returns True if entry has given mask or masks and False otherwise.

Boolean isSelected()

Returns True if entry is selected and False otherwise. This method is deprecated. Use the Selected property instead.

Boolean IsVisible()

Returns True if entry is visible and False otherwise.

MoveTo(Number x, Number y, Number sizeX, Number sizeY)

Moves entry to specified rectangle. All parameters are in points. Both X and Y size should be greater than zero.

**Obtained From**

- LayoutEntry (Owner)
- LayoutEntrySet (Item)
- LayoutWindow (ActiveEntry)

**See Also**

Scripting Reference
**LayoutEntrySet Object**
Set of layout entries.

**Properties**

- Application: Application
  Returns application. Read only.

- Number: Count
  Returns number of entries in set. Read only.

- LayoutEntry: Item(Number index)
  Returns entry with specified index. Read only.

- Component: OwnerComponent
  Returns layout component containing this set. Read only.

- Any: Parent
  Returns parent object. Read only.

**Methods**

- Add(LayoutType type)

- Add(LayoutType type, Number ownerID)

- Add(LayoutType type, LayoutEntry owner)
  Adds new entry with given type. Last two forms bound entry to a given owner entry.

- AddComponent(Component component)
  Adds new entry for given component.

- Number: ItemByID(Number id)
  Returns index of entry with given ID or -1.

- Remove(Number index)
  Removes entry with given index.

- RemoveAll()
  Removes all layout entries.

**Obtained From**

- Layout (EntrySet)

**See Also**

Scripting Reference
LayoutWindow Object
Layout window.

Properties

Component ActiveComponent
  Returns layout component shown in window. Read only.

LayoutEntry ActiveEntry
  Returns layout entry selected for editing. Read only.

Application Application
  Returns application. Read only.

Rect Bounds
  Returns the area covered by the window. Read only.

Component Component
  Returns layout component shown in window. Read only.

Number Height
  Returns window height in pixels. Read only.

Any Parent
  Returns parent object. Read only.

Number Scale
  Sets or returns display scale. Read/write.

Number ScaleInternal
  Sets or returns display scale in pixels per point (1/72 inch). Read/write.

Number Width
  Returns window width in pixels. Read only.

Methods

Close()
  Closes window.

Boolean HasActiveEntry()
  Returns True if some entry within the window is selected for editing and False otherwise.

Boolean HasScale()
  Returns True since layout window always has some scale.

Boolean HasScaleInternal()
  Returns True.

MoveTo(Branch branch)
MoveTo(BranchSet branchSet)
MoveTo(Geom geom)
MoveTo(LayoutEntry entry)
MoveTo(LayoutEntrySet entrySet)
MoveTo(Point point)
MoveTo(PointSet pointSet)
MoveTo(Rect rect)

Centers viewport on given object or set of objects. Branches, geoms, points, rects and their sets are assumed to be in the coordinate system of the page.

Refresh()

Updates window contents.

RenderTo(String name)

Renders window into an image with given name.

ZoomTo(Branch branch)
ZoomTo(BranchSet branchSet)
ZoomTo(Geom geom)
ZoomTo(LayoutEntry entry)
ZoomTo(LayoutEntrySet entrySet)
ZoomTo(Point point)
ZoomTo(PointSet pointSet)
ZoomTo(Rect rect)

Zooms to given object or set of objects. Branches, geoms, points, rects and their sets are assumed to be in the coordinate system of the page. If the bounding box of the object is a point (for example, if the object is a point), centers viewport on given object.

Obtained From

WindowSet (Item, ActiveWindow)

See Also

Scripting Reference
LookupValue Object
Value of the lookup column.

Properties

Application
Application
Returns application. Read only.

String Caption
Sets or returns value caption. Read/write.

Any Parent
Returns parent object. Read only.

Variant Value
Sets or returns value. Read/write.

Obtained From

ColumnLookupSet (Item, LastAdded, NewLookupValue)

See Also

Scripting Reference
**Map Object**
Map component.

**Properties**

Application Application
Returns application. Read only.

Color BackgroundColor
Sets or returns background color. Read / write.

Rect Box
Returns bounding box of all labels, objects and pixels in all layers. Read only.

Boolean Cached
Sets or returns caching option for shared component in Enterprise Edition. Read/write.

ControlPointSet ControlPointSet
Returns set of control points. Read only.

CoordinateSystem CoordinateSystem
Sets or returns coordinate system. Read/write.

View DefaultView
Returns default view. Read only.

String Description
Sets or returns component description. Read/write.

Document Document
Returns owner document. Read only.

Folder Folder
Sets or returns containing folder. Read/write.

Number ID
Returns unique component ID. Read only.

Boolean IsCheckedOut
Checks if component is shared and checked out in Enterprise Edition. Read only.

Boolean IsCheckedOutRemotely
Checks if component is shared and checked out by another user in Enterprise Edition. Read only.

Boolean IsModified
Checks if component is modified since last save in Enterprise Edition. Read only.

Boolean IsOutdated
Checks if component is shared and there is a later version of the component on the Enterprise server in Enterprise Edition. Read only.

Boolean IsReadOnly
Checks if component is readonly (eg, shared and not checked out) in Enterprise Edition. Read only.
Boolean IsShared
Checks if component is shared on an Enterprise server in Enterprise Edition. Read only.

Boolean IsWritable
Checks if component is writable in Enterprise Edition. Read only.

LayerSet LayerSet
Returns set of map layers. Read only.

String Name
Sets or returns component name. Read/write.

String Note
Sets or returns notes associated with the component. Read/write.

ComponentSet OwnedComponentSet
Returns set of components bound to this component. Read only.

ComponentSet OwnedLayoutSet
Returns set of layouts bound to this component. Read only.

Component Owner
Returns owner component if any. Read only.

Any Parent
Returns parent object. Read only.

Number RemoteVersion
Returns version of shared component available on the Enterprise server in Enterprise Edition. Read only.

MapSelectionSet SavedSelectionSet
Returns set of saved selections. Read only.

ObjectSet Selection
Returns set of selected drawing objects. Read only.

String Server
Returns server identification string for shared component in Enterprise Edition. Read only.

String ShareStatus
Returns textual report on component sharing status in Enterprise Edition. Read only.

ComponentType Type
Returns component type. Read only.

String TypeName
Returns textual representation of the component type. Read only.

Number Version
Returns version of shared component within the local project in Enterprise Edition. Read only.

ViewSet ViewSet
Returns set of views associated with this component. Read only.
Methods

CheckIn()
Checks in changes made to a shared component to the Enterprise server in Enterprise Edition.

CheckOut()
Checks out a shared component for editing in Enterprise Edition.

Copy()
Copies component into the Clipboard.

GetLatestVersion()
Gets the latest version of a shared component from the Enterprise server in Enterprise Edition.

Boolean IsEmpty()
Returns True if map contains no layers and False otherwise.

Open()
Opens component.

OpenInNewWindow()
Opens component in new window.

Print(Boolean useDialog)
Prints component.

RenderAreaTo(String name, Number width, Number height, Rect area, Boolean clean)
Renders component area into an image with given name, width and height. If last parameter is True, legend, north arrow and scale bar are not rendered even if they are on.

RenderTo(String name, Number width, Number height, Boolean clean)
Render component into an image with given name, width and height. If last parameter is True, legend, north arrow and scale bar are not rendered even if they are turned on.

UndoCheckOut()
Undoes changes made to a shared component and gets the latest version of the component from the Enterprise server in Enterprise Edition.

MapSelectionSet Object
Set of saved selections within map.

Properties

Application Application
  Returns application. Read only.

Number Count
  Returns number of selections in set. Read only.

ObjectSet Item(Number index)
  Returns selection with given index. Read only.

Any Parent
  Returns parent object. Read only.

Methods

Number ItemByMask(Number mask)
  Returns index of selection with given mask value or -1.

Number ItemByName(String name)
  Returns index of selection with given name or -1.

Obtained From

Map (SavedSelectionSet)

See Also

Scripting Reference
MapServer Object
Mapserver object (Internet Map Server).

Properties

Application Application
Returns application. Read only.

Component Component
Returns served component. Read only.

String Copyright
Sets or returns copyright text. Read/write.

Number CurrentSessions
Returns the number of currently connected users. Can not be less than 1 (for obvious reasons). Read only.

Number CX
Sets or returns width of visible area in pixels. Read/write.

Number CY
Sets or returns height of visible area in pixels. Read/write.

Rect DataBox
Returns the bounding box of all data in served component. Read only.

Document Document
Returns served document. Read only.

String Fields
Returns list of searchable fields separated by newline characters. Read only.

Date FirstHitDate
Returns the date the first MapServer object was created. Uses the local time of the server. Read only.

Number Hits
Returns the total number of created MapServer objects since startup. Read only.

Date LastHitDate
Returns the date the last MapServer object was created. Uses the local time of the server. Read only.

Date LastReloadDate
Returns the date of the last reload. Uses the local time of the server. Read only.

String Layers
Returns list of layers separated by newline characters. Read only.

Boolean LayerShown(Number layer)
Boolean LayerShown(String layer)
Returns True if layer with given index or name is shown and False otherwise. Read only.

String Location
Returns textual representation of current location. Read only.

String Queries
Returns list of queries separated by newline characters. Read only.

String QueryParameters(Number query)
String QueryParameters(String query)
Returns list of parameters for query with given index or name separated by newline characters. Read only.

MapServerRenderFormat RenderFormat
Sets or returns rendering format. Read/write.

String RenderOptions
Sets or returns rendering options, specified as a sequence of tokens separated by whitespace characters. Support for rendering options varies between different rendering formats. For the complete list of supported rendering options, see the IMS Config.txt Options topic. Read/write.

String RenderParameters(String name)
Sets or returns the parameters for the drawing with the given name linked from a parameter query. Read/write.

Number RenderQuality
Sets or returns rendering quality, in the range of 1 to 100, with 100 meaning maximum quality. Support for rendering quality varies between different rendering formats. Read/write.

String Result
Returns result of information request, query or search. Read only.

String ResultRaw
Returns result of information request, query or search as <table>...</table> HTML fragment. Read only.

String ResultXml
Returns result of information request, query or search in XML format. Read only.

String Scale
Returns textual representation of current scale. Read only.

String State
Returns state string. Read only.

String Subtitle
Sets or returns subtitle text. Read/write.

String Target
Returns redirection URL if any. Read only.

String Title
Sets or returns title text. Read/write.

Number ViewCenterX
Sets or returns the X coordinate of the center location in native coordinates of the served component. Read/write.

Number ViewCenterY
Sets or returns the Y coordinate of the center location in native coordinates of the served component. Read/write.

String Views
Returns list of views separated by newline characters. Read only.

Number ViewScaleX
Sets or returns the number of native data units per pixel in X direction. Read/write.

Number ViewScaleY
Sets or returns the number of native data units per pixel in Y direction. Read/write.

Methods

Boolean _GetLayerShown(Number layer)
Boolean _GetLayerShown(String layer)
Returns True if layer with given index or name is shown and False otherwise. Provided as a way to use the LayerShown property in languages that do not support parameterized properties.

String _GetQueryParameters(Number query)
String _GetQueryParameters(String query)
Returns list of parameters for query with given index or name separated by newline characters. Provided as a way to use the QueryParameters property in languages that do not support parameterized properties.

String _GetRenderParameters(String name)
Returns the parameters for the drawing with the given name linked from a parameter query. Provided as a way to use the RenderParameters property in languages that do not support parameterized properties.

_putRenderParameters(String name, String value)
Sets the parameters for the drawing with the given name linked from a parameter query. Provided as a way to use the RenderParameters property in languages that do not support parameterized properties.

Center(Number x, Number y)
Center view at given location.

Click(Number x, Number y)
Request information at given location.

Create(String config, String state, Object server)
Initialize web server with given configuration file, state and IIS server object. The server object is used to format HTML data and is optional.

CreateWithFile(String project, String component, String state, Object server, Boolean useCache)
Initialize web server with given MAP file, component name, state and IIS server object. The server object is used to format HTML data and is optional. The last parameter controls the use of an option cache. The option cache associates each set of options with the ID of the served component and other data, which does not usually need to be recomputed from scratch for each instance of the MapServer object. It might be desired to avoid using the option cache if a component served by the MapServer object is generated on the fly. Passing true or omitting the parameter uses the option cache. Passing false does not use the option cache.

CreateWithOpts(String configOpts, String state, Object server, Boolean useCache)
Initialize web server with given configuration options, state and IIS server object. The server object is used to format HTML data and is optional. The last parameter controls the use of an option cache (see the description of the CreateWithFile method for details).

MapServerOgcWms CreateOgcWmsDriver()
Creates new OGC WMS driver object linked to this MapServer object.
GoToView(String view)
Jump to view with given name.

Boolean HasInfoAt(Number x, Number y)
Returns True if clicking given location with the Info tool will yield some data and False otherwise.

Boolean HasLinkAt(Number x, Number y)
Returns True if clicking given location will follow a hyperlink and False otherwise.

Locate(String what, String where, Boolean zoom)
Search for given text in given field and zoom to found objects if any. The last parameter is optional.

Number MapX(Number x)
Maps X coordinate of rendered image to that of served component.

Number MapY(Number y)
Maps Y coordinate of rendered image to that of served component.

Query(Number query, String parameters, Boolean force, Boolean zoom)
Perform query with given index or name using given set of parameters forcing recomputation and zooming the mapserver to the results of the query if desired. The values of the parameters are separated by newline characters. If the force parameter is omitted, the recomputation is not forced. If the zoom parameter is omitted, the mapserver zooms to the results of the query.

Reload()
Reloads all MAP files used by all web sites on a system the MapServer object has been instantiated on. Renders all MapServer objects in the current request queue inoperable.

Object Render()
Render current view to PNG file.

Object RenderLegend()
Render legend to PNG file.

Strafe(String direction)
Strafe view in given direction. The constants are "n", "ne", "e", "se", "s", "sw", "w" and "nw". Case does not matter

TurnLayer(Number layer, Boolean on)
Turn layer with given index or name on or off.

TurnLayer(String layer, Boolean on)

ZoomIn(Number x, Number y, Number factor)
Center current view at given location and increase zoom using given magnification factor. The magnification factor is a value from 1.1 to 4.0. If the magnification factor is omitted, the default magnification factor is used (normally, 2.0).

ZoomOut(Number x, Number y, Number factor)
Center current view at given location and decrease zoom using given magnification factor. The magnification factor is a value from 1.1 to 4.0. If the magnification factor is omitted, the default magnification factor is used (normally, 2.0).

ZoomToFit()
Zoom to see all data.
The RenderParameters property

The RenderParameters property is used to supply parameters to drawings linked from parameter queries to facilitate the use of such drawings by multiple users. The passed parameters are not persisted in the state string and are only valid for the lifetime of a given instance of the MapServer object.

The MapServer object refreshes images and surfaces linked from parameter queries prior to rendering, using the values of the RenderParameters property.

The logic used by the MapServer object to refresh components linked from parameter queries will skip re-computing queries the parameters of which did not change. This increases performance for simple scenarios of using components linked from parameter queries, but requires writing additional refresh code for complex scenarios.

Example

Suppose we have an IMS site that displays a map containing a drawing of cities named Cities. The drawing is linked to a parameter query that takes XY coordinates entered by the user and returns all cities close to that XY location.

Adding the following lines prior to a call to the Render method of the MapServer object will make the system customize the display using the values provided by the user:

```javascript
var locX = parameter("locX", ""); // value provided by the user
var locY = parameter("locY", ""); // value provided by the user
if (locX != "" && locY != "")
    mapserver.RenderParameters("Cities") = locX + "\n" + locY;
```

Comments

Regarding the state property of the MapServer object, more precisely the viewport parameter: The viewport is composed of four separate variables, ScaleX, ScaleY, CenterX and CenterY. The ScaleX and ScaleY parameters store the number of native coordinate system units in a pixel in the X and Y directions respectively.

Let's say we have a map in some coordinate system. Let's say the coordinate system unit is in feet and the local scale parameters are 5 and 2. Therefore, one native coordinate system unit is 5 feet "wide" and 2 feet "tall". Let's say that both the ScaleX and ScaleY parameters of the viewport are 10. Therefore, one pixel in the IMS view covers an area of 50 feet x 20 feet.

Creating an instance of the MapServer object with an empty state string (for example, for the first time in a session for a particular user) automatically goes to the view named Startup (case insensitive) if such a view exists. See the Views pane topic.

See the IMS programming examples in the Free Stuff web page to understand how to use the MapServer object.

See Also

Scripting Reference
MapServerOgcWms Object
OGC WMS interface driver for Internet Map Server.

Properties

Application Application
  Returns application. Read only.

Any Parent
  Returns parent object. Read only.

Any Result
  Returns response data for the processed WMS command. Read only.

String ResultContentType
  Returns content type of the response data for the processed WMS command. Read only.

Methods

Boolean Handle(String command, String url)
  Process the WMS command. The second parameter is an URL of the ASP page (used to compose the server capabilities document) and is optional. Returns True if the command has been processed successfully and False otherwise.

Obtained From

MapServer (CreateOgcWmsDriver)

See Also

Scripting Reference
MapWindow Object
Map window.

Properties

Component ActiveComponent
Returns active layer component. Read only.

Label ActiveLabel
Returns label selected for editing. Read only.

Object ActiveObject
Returns object selected for editing. Read only.

Application Application
Returns application. Read only.

Rect Bounds
Returns the area covered by the window, in the coordinate system of the displayed component. Read only.

Component Component
Returns map component shown in window. Read only.

Number Height
Returns window height in pixels. Read only.

Point Location
Sets or returns viewport center. Read/write.

Point LocationLatLon
Sets or returns viewport center in lat/lon coordinates. Read/write.

Any Parent
Returns parent object. Read only.

Number Scale
Sets or returns viewport scale (projected components only). Read/write.

Number ScaleInternal
Sets or returns internal pixel-to-data ratio. Read/write.

Number Width
Returns window width in pixels. Read only.

Methods

Close()
Closes window.

Boolean HasActiveLabel()
Returns True if some label within the window is selected for editing and False otherwise.
Boolean HasActiveObject()
Returns True if some object within the window is selected for editing and False otherwise.

Boolean HasLocation()
Returns True if viewport center can be modified and False otherwise.

Boolean HasScale()
Returns True if viewport scale can be obtained or modified and False otherwise.

Boolean HasScaleInternal()
Returns True.

MoveTo(Branch branch)
MoveTo(BranchSet branchSet)
MoveTo(Component component)
MoveTo(Geom geom)
MoveTo(Label label)
MoveTo(LabelSet labelSet)
MoveTo(Object object)
MoveTo(ObjectSet objectSet)
MoveTo(Pixel pixel)
MoveTo(PixelSet pixelSet)
MoveTo(Point point)
MoveTo(PointSet pointSet)
MoveTo(Rect rect)
Centers viewport on given object or set of objects. Branches, geoms, points, rects and their sets are assumed to be in the coordinate system of the displayed component.

MoveToLocation(Point point, Boolean latLon)
Centers viewport on given location. LatLon parameter is optional.

Refresh()
Updates window contents.

RenderTo(String name)
Renders window into an image with given name.

ZoomTo(Branch branch)
ZoomTo(BranchSet branchSet)
ZoomTo(Component component)
ZoomTo(Geom geom)
ZoomTo(Label label)
ZoomTo(LabelSet labelSet)
ZoomTo(Object object)
ZoomTo(ObjectSet objectSet)
ZoomTo(Pixel pixel)
ZoomTo(PixelSet pixelSet)
ZoomTo(Point point)
ZoomTo(PointSet pointSet)
ZoomTo(Rect rect)
Zooms to given object or set of objects. Branches, geoms, points, rects and their sets are assumed to be in the coordinate system of the displayed component. If the bounding box of the object is a point (for example, if the object is a point), centers viewport on given object.

Scripting Reference
**Object**

Drawing object.

**Properties**

```
Application Application
Returns application. Read only.

Color BackColor
Returns background color. Read only.

Color BorderBackColor
Returns border background color. Read only.

Color BorderForeColor
Returns border foreground color. Read only.

Number BorderSize
Returns border size. Read only.

Number BorderStyle
Returns border style. Read only.

Geom ChangeGeomLocal
Gets the local version of the object metric in case the object belongs to a linked drawing and participates in an editing conflict. Read only.

Geom ChangeGeomRemote
Gets the remote version of the object metric in case the object belongs to a linked drawing and participates in an editing conflict. Read only.

Color ForeColor
Returns foreground color. Read only.

Geom Geom
Sets or returns object metric. Read/write.

Boolean HasLocalChanges
Returns True if the object belongs to a linked drawing and participates in an editing conflict, and False otherwise. Read only.

Number ID
Returns unique object ID. Read only.

Number Mask
Sets or returns object mask. Read/write.

Component OwnerComponent
Returns drawing component containing this object. Read only.

Any Parent
Returns parent object. Read only.
```
Record

Returns the record associated with the drawing object. Read only.

Boolean Selected

Selects or deselects object or checks if object is selected. Read/write.

Number Size

Returns object size. Read only.

Number Style

Returns object style. Read only.

ObjectType Type

Returns object type. Read only.

String TypeName

Returns textual representation of object type. Read only.

Methods

Boolean CommitLocalChanges()
Commits local changes to an object that belongs to a linked drawing and participates in an editing conflict, and uploads them to the drawing's data source. Returns True if, at the end of the method call, the object does not participate in an editing conflict and False otherwise.

Boolean DiscardLocalChanges()
Discards local changes to an object that belongs to a linked drawing and participates in an editing conflict, and retrieves the latest data for the object from the drawing's data source. Returns True if, at the end of the method call, the object does not participate in an editing conflict and False otherwise.

Boolean IsClean()
Returns True if object metric has been normalized and False otherwise.

Boolean IsConvex()
Returns True if area represented by the object is convex and False otherwise.

Boolean IsMasked(Number mask)
Returns True if object has given mask or masks and False otherwise.

Boolean IsSelected()
Returns True if object is selected and False otherwise. This method is deprecated. Use the Selected property instead.

ObjectSet Object
Set of objects. Can represent all objects in a particular component or an arbitrary set of objects in one or more components. In the first case, the set is considered to contain objects, and the Add and Remove methods add and remove objects from the component. In the second case, the set is considered to contain references to objects, and the Add and Remove methods alter the content of the object set without adding or removing objects from components.

Properties
Application Application
Returns application. Read only.

Rect Box
Returns bounding box of all objects in set. Read only.

Number Count
Returns number of objects in set. Read only.

Number CountAreas
Returns number of areas in set. Read only.

Number CountLines
Returns number of lines in set. Read only.

Number CountPoints
Returns number of points in set. Read only.

GeomSet GeomSet
Returns geometric entities representing a set. Read only.

Object Item(Number index)
Returns object with given index. Read only.

Object LastAdded
Returns last added object if any. Read only.

Number Mask
Returns mask value. Read only.

String Name
Returns name of set. Read only.

Component OwnerComponent
Returns drawing component containing this set. Read only.

Any Parent
Returns parent object. Read only.

Methods
Add(Geom geom)
Creates new object with given metric and adds it to a set which contains objects.
Add(Object object)
Adds object to a set which contains references to objects.

Boolean IsStatic()
Returns True if object set is static and False otherwise.

Boolean IsSystem()
Returns True if object set is system and False otherwise.

Number ItemByID(Number id)
Returns index of object with given ID or -1.

Remove(Number index)
Removes object with given index.

RemoveAll()
Removes all objects.

**Palette Object**
Palette component.

**Properties**

- **Application**
  Returns application. Read only.

- **Cached**
  Sets or returns caching option for shared component in Enterprise Edition. Read/write.

- **ColorSet**
  Returns set of palette colors. Read only.

- **Description**
  Sets or returns component description. Read/write.

- **Document**
  Returns owner document. Read only.

- **Folder**
  Sets or returns containing folder. Read/write.

- **ID**
  Returns unique component ID. Read only.

- **IsCheckedOut**
  Checks if component is shared and checked out in Enterprise Edition. Read only.

- **IsCheckedOutRemotely**
  Checks if component is shared and checked out by another user in Enterprise Edition. Read only.

- **IsModified**
  Checks if component is modified since last save in Enterprise Edition. Read only.

- **IsOutdated**
  Checks if component is shared and there is a later version of the component on the Enterprise server in Enterprise Edition. Read only.

- **IsReadOnly**
  Checks if component is readonly (e.g., shared and not checked out) in Enterprise Edition. Read only.

- **IsShared**
  Checks if component is shared on an Enterprise server in Enterprise Edition. Read only.

- **IsWritable**
  Checks if component is writable in Enterprise Edition. Read only.

- **Name**
  Sets or returns component name. Read/write.

- **Note**
  Sets or returns notes associated with the component. Read/write.
ComponentSet OwnedComponentSet
Returns set of components bound to this component. Read only.

ComponentSet OwnedLayoutSet
Returns set of layouts bound to this component. Read only.

Component Owner
Returns owner component if any. Read only.

Any Parent
Returns parent object. Read only.

Number RemoteVersion
Returns version of shared component available on the Enterprise server in Enterprise Edition. Read only.

PaletteSelectionSet SavedSelectionSet
Returns set of saved selections. Read only.

ColorSet Selection
Returns set of selected colors. Read only.

String Server
Returns server identification string for shared component in Enterprise Edition. Read only.

String ShareStatus
Returns textual report on component sharing status in Enterprise Edition. Read only.

ComponentType Type
Returns component type. Read only.

String TypeName
Returns textual representation of the component type. Read only.

Number Version
Returns version of shared component within the local project in Enterprise Edition. Read only.

**Methods**

CheckIn()
Checks in changes made to a shared component to the Enterprise server in Enterprise Edition.

CheckOut()
Checks out a shared component for editing in Enterprise Edition.

Clear(Boolean selection)
Clears entire component or selection within the component. Calling the method without parameters clears entire component.

Copy(Boolean selection)
Copies entire component or selection within the component into the Clipboard. Calling the method without parameters copies entire component.
Cut(Boolean selection)
Copies entire component or selection within the component into the Clipboard and then clears it. Calling the method without parameters cuts entire component.

GetLatestVersion()
Gets the latest version of a shared component from the Enterprise server in Enterprise Edition.

Open()
Opens component.

OpenInNewWindow()
Opens component in new window.

Paste(Boolean replace)
Pastes the contents of the Clipboard into the component replacing current selection or leaving it intact. Calling the method without parameters replaces selection.

Print(Boolean useDialog)
Prints component.

UndoCheckOut()
Undoes changes made to a shared component and gets the latest version of the component from the Enterprise server in Enterprise Edition.

Pixel of image or surface.

**Properties**

Application Application
Returns application. Read only.

Number Channel(Number index)
Sets or returns value in given channel. Read/write.

Color Color
Sets or returns color. Read/write.

Number Mask
Sets or returns pixel mask. Read/write.

Component OwnerComponent
Returns image or surface component containing this pixel. Read only.

Any Parent
Returns parent object. Read only.

Boolean Selected
Selects or deselects pixel or checks if pixel is selected. Read/write.

Number Value
Sets or returns value associated with pixel. Read/write.

Variant ValueNative
Returns native value associated with pixel. Read only.

Boolean Visible
Sets or returns pixel visibility flag. Read/write.

Number X
Returns X coordinate of pixel within image or surface. Read only.

Number Y
Returns Y coordinate of pixel within image or surface. Read only.

**Methods**

Number _GetChannel(Number index)
Returns value in given channel. Provided as a way to use the Channel property in languages that do not support parameterized properties.

_PutChannel(Number index, Number value)
Sets value in given channel. Provided as a way to use the Channel property in languages that do not support parameterized properties.

Boolean IsInvisible()
Returns True if pixel is invisible and False otherwise. This method is deprecated. Use the Visible property instead.
Boolean IsMasked(Number mask)
Returns True if pixel has given mask or masks and False otherwise.

Boolean IsMissing()
Returns True if pixel is invisible and False otherwise. This method is deprecated. Use the Visible property instead.

Boolean IsSelected()
Returns True if pixel is selected and False otherwise. This method is deprecated. Use the Selected property instead.

Returns number of pixels in set.  Read only.

Pixel Item(Number index)
Returns pixel with given index.  Read only.

Number ItemByXY(Number x, Number y)
Returns index of pixel with given X and Y coordinates or -1.

Pixel LastAdded
    Returns last added pixel if any. Read only.

Number Mask
Returns mask value.  Read only.

String Name
Returns name of set.  Read only.

Component OwnerComponent
Returns image or surface component containing this set.  Read only.

Any Parent
Returns parent object.  Read only.

Number ValueMax
Returns maximum value of pixel in set.  Read only.

Number ValueMin
Returns minimum value of pixel in set.  Read only.

Methods

Number _GetItemByXY(Number x, Number y)
Returns index of pixel with given X and Y coordinates or -1. Provided as a way to use the ItemByXY property in languages that do not support parameterized properties.

Add(Number x, Number y)
Add a pixel at a given location to the selection or a saved selection.

Boolean IsSystem()
Returns True if pixel set is system and False otherwise.
Remove(Number index)
Removes a pixel with given index from the selection or a saved selection.

RemoveAll()
Clears the selection or a saved selection.

TransformWith(String formula)
Transforms pixel set according to specified formula. Only works on surfaces. Requires Surface Tools extension.

Profile Object
Profile component.

Properties

Application Application
  Returns application. Read only.

Number AvgHeight
  Returns average height of the profile. Read only.

Color BackgroundColor
  Sets or returns background color. Read / write.

Boolean Cached
  Sets or returns caching option for shared component in Enterprise Edition. Read/write.

ControlPointSet ControlPointSet
  Returns set of control points. Read only.

Boolean Coordinates
  Turns coordinate display on or off. Read/write.

CoordinateSystem CoordinateSystem
  Sets or returns coordinate system. Read/write.

Boolean DecimalDigits
  Sets or returns the number of decimal digits used for height reports. Read/write.

View DefaultView
  Returns default view. Read only.

String Description
  Sets or returns component description. Read/write.

Document Document
  Returns owner document. Read only.

Folder Folder
  Sets or returns containing folder. Read/write.

Number ID
  Returns unique component ID. Read only.

Boolean IsCheckedOut
  Checks if component is shared and checked out in Enterprise Edition. Read only.

Boolean IsCheckedOutRemotely
  Checks if component is shared and checked out by another user in Enterprise Edition. Read only.

Boolean IsModified
  Checks if component is modified since last save in Enterprise Edition. Read only.
Boolean IsOutdated
Checks if component is shared and there is a later version of the component on the Enterprise server in Enterprise Edition. Read only.

Boolean IsReadOnly
Checks if component is readonly (eg, shared and not checked out) in Enterprise Edition. Read only.

Boolean IsShared
Checks if component is shared on an Enterprise server in Enterprise Edition. Read only.

Boolean IsWritable
Checks if component is writable in Enterprise Edition. Read only.

Number MaxHeight
Returns maximum height within the profile. Read only.

Geom Metric
Sets or returns profile metric (can accept BranchSet, Branch, or PointSet when setting). Read/write.

Number MinHeight
Returns minimum height within the profile. Read only.

String Name
Sets or returns component name. Read/write.

String Note
Sets or returns notes associated with the component. Read/write.

ComponentSet OwnedComponentSet
Returns set of components bound to this component. Read only.

ComponentSet OwnedElevationSet
Returns set of elevations bound to this component. Read only.

ComponentSet OwnedLayoutSet
Returns set of layouts bound to this component. Read only.

Component Owner
Returns owner component if any. Read only.

Any Parent
Returns parent object. Read only.

Number RemoteVersion
Returns version of shared component available on the Enterprise server in Enterprise Edition. Read only.

String Server
Returns server identification string for shared component in Enterprise Edition. Read only.

String ShareStatus
Returns textual report on component sharing status in Enterprise Edition. Read only.
ComponentType Type
   Returns component type. Read only.

String TypeName
   Returns textual representation of the component type. Read only.

Number Version
   Returns version of shared component within the local project in Enterprise Edition. Read only.

ViewSet ViewSet
   Returns set of views associated with this component. Read only.

Number ZoomMax
   Sets or returns maximum zoom level. Read/write.

Number ZoomMin
   Sets or returns minimum zoom level. Read/write.

Number ZoomRender
   Sets or returns render zoom level. Read/write.

Methods

CheckIn()
   Checks in changes made to a shared component to the Enterprise server in Enterprise Edition.

CheckOut()
   Checks out a shared component for editing in Enterprise Edition.

Copy()
   Copies component into the Clipboard.

GetLatestVersion()
   Gets the latest version of a shared component from the Enterprise server in Enterprise Edition.

Boolean IsEmpty()
   Returns True if profile contains no entries and False otherwise.

Open()
   Opens component.

OpenInNewWindow()
   Opens component in new window.

Print(Boolean useDialog)
   Prints component.

RenderAreaTo(String name, Number width, Number height, Rect area, Boolean clean)
   Renders component area into an image with given name, width and height. If last parameter is True, legend,
   north arrow and scale bar are not rendered even if they are on.

RenderTo(String name, Number width, Number height, Boolean clean)
Render component into an image with given name, width and height. If last parameter is True, legend, north arrow and scale bar are not rendered even if they are turned on.

UndoCheckOut()
Undoes changes made to a shared component and gets the latest version of the component from the Enterprise server in Enterprise Edition.

Query Object
Query component.

Properties

Boolean Ansi
Sets or returns the ANSI-compatible syntax option. Read/write.

Application Application
Returns application. Read only.

Boolean Cached
Sets or returns caching option for shared component in Enterprise Edition. Read/write.

String Description
Sets or returns component description. Read/write.

Document Document
Returns owner document. Read only.

Folder Folder
Sets or returns containing folder. Read/write.

Number ID
Returns unique component ID. Read only.

Boolean IsCheckedOut
Checks if component is shared and checked out in Enterprise Edition. Read only.

Boolean IsCheckedOutRemotely
Checks if component is shared and checked out by another user in Enterprise Edition. Read only.

Boolean IsModified
Checks if component is modified since last save in Enterprise Edition. Read only.

Boolean IsOutdated
Checks if component is shared and there is a later version of the component on the Enterprise server in Enterprise Edition. Read only.

Boolean IsReadOnly
Checks if component is readonly (e.g., shared and not checked out) in Enterprise Edition. Read only.

Boolean IsShared
Checks if component is shared on an Enterprise server in Enterprise Edition. Read only.

Boolean IsWritable
Checks if component is writable in Enterprise Edition. Read only.

Number Length
Returns number of characters in query text. Read only.

String Name
Sets or returns component name. Read/write.
String Note
Sets or returns notes associated with the component. Read/write.

ComponentSet OwnedComponentSet
Returns set of components bound to this component. Read only.

ComponentSet OwnedLayoutSet
Returns set of layouts bound to this component. Read only.

Component Owner
Returns owner component if any. Read only.

QueryParameterSet ParameterSet
Returns set of query parameters. Read only.

Any Parent
Returns parent object. Read only.

QueryType QueryType
Returns type of query. Read only.

Number RemoteVersion
Returns version of shared component available on the Enterprise server in Enterprise Edition. Read only.

String Server
Returns server identification string for shared component in Enterprise Edition. Read only.

String ShareStatus
Returns textual report on component sharing status in Enterprise Edition. Read only.

Table Table
Returns query table. Read only.

String Text
Sets or returns query text. Read/write.

ComponentType Type
Returns component type. Read only.

String TypeName
Returns textual representation of the component type. Read only.

Number Version
Returns version of shared component within the local project in Enterprise Edition. Read only.

Methods

AddText(String text)
Appends text to the end of the component.

CheckIn()
Checks in changes made to a shared component to the Enterprise server in Enterprise Edition.
CheckOut()
Checks out a shared component for editing in Enterprise Edition.

Clear()
Clears component.

Copy()
Copies component into the Clipboard.

Cut()
Copies component into the Clipboard and then clears it.

Boolean EditParameters()
Edits parameters of a parameter query in a dialog. Returns True if editing has been accepted and False otherwise.

GetLatestVersion()
Gets the latest version of a shared component from the Enterprise server in Enterprise Edition.

Boolean IsEmpty(Boolean ignoreWhiteSpaces)
Returns True if component text is empty and False otherwise.

Boolean IsValid()
Returns True if query text does not contain syntax errors and False otherwise.

Open()
Opens component.

OpenInNewWindow()
Opens component in new window.

Paste(Boolean replace)
Pastes the contents of the Clipboard into the component replacing previous data or adding to it. Calling the method without parameters replaces data.

Print(Boolean useDialog)
Prints component.

Run()
Runs query.

RunEx(Boolean force)
Runs query forcing recomputation if desired.

UndoCheckOut()
Undoes changes made to a shared component and gets the latest version of the component from the Enterprise server in Enterprise Edition.

Properties

Application Application
Returns application. Read only.

Number Count
Returns number of parameters in set. Read only.

QueryParameter Item(Number index)
QueryParameter Item(String name)
Returns parameter with given index or name. Read only.

Any Parent
Returns parent object. Read only.

Methods

Number ItemByName(String name)
Returns index of parameter with given name or -1.

Obtained From

Query (ParameterSet)

Scripting Reference
**RecentDataSource Object**
Connection information for a recently used data source.

**Properties**

**Application Application**
Returns application. Read only.

**ConnectionString**
Returns connection string. Read only.

**ConnectionType**
Returns connection type. For the list of supported connection types see the topic on the DataSource object. Read only.

**Name**
Returns data source name. Read only.

**Parent**
Returns parent object. Read only.

**Obtained From**

RecentDataSourceSet (Item)

**See Also**

Scripting Reference
**RecentDataSourceSet Object**
A set of recently used data sources.

**Properties**

- **Application Application**
  - Returns application. Read only.

- **Number Count**
  - Returns number of data sources in set. Read only.

- **RecentDataSource Item(Number index)**
- **RecentDataSource Item(String name)**
  - Returns data source with given index or name. Read only.

- **Any Parent**
  - Returns parent object. Read only.

**Methods**

- **Number ItemByName(String name)**
  - Returns the index of a data source with given name, or -1.

**Obtained From**

- Application (RecentDataSourceSet)

**See Also**

- Scripting Reference
**Record Object**
Table record.

**Properties**

- **Application**
  Returns application. Read only.

- **Variant Data(Column column)**
  **Variant Data(Number id)**
  **Variant Data(String name)**
  Sets or returns data for given column. Column can be supplied directly or by its ID or name. Read/write.

- **Variant DataByIndex(Number index)**
  Sets or returns data for column with given index. Read/write.

- **String DataText(Column column)**
  **String DataText(Number id)**
  **String DataText(String name)**
  Returns textual representation of data in given column. Column can be supplied directly or by its ID or name. Read only.

- **String DataTextByIndex(Number index)**
  Returns textual representation of data in column with given index. Read only.

- **Number ID**
  Returns unique record ID. Read only.

- **Number Index**
  Returns the index of this record in the record set. Read only.

- **Number Mask**
  Sets or returns record mask. Read/write.

- **Object**
  Returns the drawing object associated with the record. If the table is not bound to a drawing, returns an empty value. Read only.

- **Component OwnerComponent**
  Returns table component containing this record if any. Read only.

- **Any Parent**
  Returns parent object. Read only.

- **Boolean Selected**
  Selects or deselects record or checks if record is selected. Read/write.

**Methods**

- **Variant _GetData(Column column)**
- **Variant _GetData(Number id)**
- **Variant _GetData(String name)**
Programming Reference

Returns data for given column. Column can be supplied directly or by its ID or name. Provided as a way to use the Data property in languages that do not support parameterized properties.

Variant _GetDataByIndex(Number index)

Returns data for column with given index. Provided as a way to use the DataByIndex property in languages that do not support parameterized properties.

String _GetDataText(Column column)
String _GetDataText(Number id)
String _GetDataText(String name)

Returns textual representation of data in given column. Column can be supplied directly or by its ID or name. Provided as a way to use the DataText property in languages that do not support parameterized properties.

String _GetDataTextByIndex(Number index)

Returns textual representation of data in column with given index. Provided as a way to use the DataTextByIndex property in languages that do not support parameterized properties.

_PutData(Column column, Variant value)
_PutData(Number id, Variant value)
_PutData(String name, Variant value)

Sets data for given column. Column can be supplied directly or by its ID or name. Provided as a way to use the Data property in languages that do not support parameterized properties.

_PutDataByIndex(Number index, Variant value)

Sets data for column with given index. Provided as a way to use the DataByIndex property in languages that do not support parameterized properties.

Boolean IsMasked(Number mask)

Returns True if record has given mask or masks and False otherwise.

Boolean IsSelected()

Returns True if record is selected and False otherwise. This method is deprecated. Use the Selected property instead.

Obtained From

Object (Record)
RecordSet (Item, LastAdded)
TableWindow (ActiveRecord)

See Also

Scripting Reference
RecordSet Object
Set of table records.

Properties

Application Application
Returns application. Read only.

Number Count
Returns number of records in set. Read only.

Record Item(Number index)
Returns record with given index. Read only.

Record LastAdded
Returns last added record if any. Read only.

Component OwnerComponent
Returns table component containing this record if any. Read only.

Any Parent
Returns parent object. Read only.

Methods

Add(Record record)
Appends record to the record set. Adds a new record to the table if the record set represents all table records. Selects the record or adds the record to the saved selection if the record set represents the selection or a saved selection.

AddNew()
Appends new record to set.

Number Average(Column column)
Number Average(Number id)
Number Average(String name)
Returns average value of given column. Column can be supplied directly or by its ID or name.

RecordSet Bottom(Column column, Number count)
RecordSet Bottom(Number id, Number count)
RecordSet Bottom(String name, Number count)
Returns given number of bottom records for given column. Column can be supplied directly or by its ID or name.

Number CenterCorrelation(Column column, Column columnSecond)
Number CenterCorrelation(Number id, Number idSecond)
Number CenterCorrelation(String name, String stringSecond)
Returns central correlation of given pair of columns. Columns can be supplied directly or by their IDs or names.

Number CenterCovariation(Column column, Column columnSecond)
Number CenterCovariation(Number id, Number idSecond)
Number CenterCovariation(String name, String stringSecond)
Returns central covariance of given pair of columns. Columns can be supplied directly or by their IDs or names.
Number CenterMoment(Column column, Number order)
Number CenterMoment(Number id, Number order)
Number CenterMoment(String name, Number order)
Returns central momentum of given order for given column. Column can be supplied directly or by its ID or name.

RecordSet Containing(Column column, Variant value)
RecordSet Containing(Number id, Variant value)
RecordSet Containing(String name, Variant value)
Returns records containing given value in given column. Column can be supplied directly or by its ID or name.

RecordSet ContainingMatch(Column column, String pattern)
RecordSet ContainingMatch(Number id, String pattern)
RecordSet ContainingMatch(String name, String pattern)
Returns records containing a match to given pattern in given column. Column can be supplied directly or by its ID or name.

RecordSet ContainingToken(Column column, String token)
RecordSet ContainingToken(Number id, String token)
RecordSet ContainingToken(String name, String token)
Returns records containing given token in given column. Column can be supplied directly or by its ID or name.

Number Correlation(Column column, Column columnSecond)
Number Correlation(Number id, Number idSecond)
Number Correlation(String name, String stringSecond)
Returns correlation of given pair of columns. Columns can be supplied directly or by their IDs or names.

Number Covariation(Column column, Column columnSecond)
Number Covariation(Number id, Number idSecond)
Number Covariation(String name, String stringSecond)
Returns covariation of given pair of columns. Columns can be supplied directly or by their IDs or names.

RecordSet Duplicates(Column column)
RecordSet Duplicates(Number id)
RecordSet Duplicates(String name)
Returns records containing duplicate values of given column. Column can be supplied directly or by its ID or name.

RecordSet DuplicatesExceptFirst(Column column)
RecordSet DuplicatesExceptFirst(Number id)
RecordSet DuplicatesExceptFirst(String name)
Returns record containing duplicate values (except first such value) of given column. Column can be supplied directly or by its ID or name.

RecordSet EndingWith(Column column, String text)
RecordSet EndingWith(Number id, String text)
RecordSet EndingWith(String name, String text)
Returns records whose values in given column end with specified text. Column can be supplied directly or by its ID or name.

RecordSet EndingWithMatch(Column column, String pattern)
RecordSet EndingWithMatch(Number id, String pattern)
RecordSet EndingWithMatch(String name, String pattern)
Returns records whose values in given column end with match to given pattern. Column can be supplied directly or by its ID or name.
RecordSet EndingWithToken(Column column, String token)
RecordSet EndingWithToken(Number id, String token)
RecordSet EndingWithToken(String name, String token)
Returns records whose values in given column end with given token. Column can be supplied directly or by its ID or name.

RecordSet EqualTo(Column column, Variant value)
RecordSet EqualTo(Number id, Variant value)
RecordSet EqualTo(String name, Variant value)
Returns records with values of given column equal to given value. Column can be supplied directly or by its ID or name.

Number Excess(Column column)
Number Excess(Number id)
Number Excess(String name)
Returns excess of given column. Column can be supplied directly or by its ID or name.

RecordSet GreaterOrEqualTo(Column column, Variant value)
RecordSet GreaterOrEqualTo(Number id, Variant value)
RecordSet GreaterOrEqualTo(String name, Variant value)
Returns records with values of given column greater than or equal to given value. Column can be supplied directly or by its ID or name.

RecordSet GreaterThan(Column column, Variant value)
RecordSet GreaterThan(Number id, Variant value)
RecordSet GreaterThan(String name, Variant value)
Returns records with values of given column greater than given value. Column can be supplied directly or by its ID or name.

Number ItemByID(Number id)
Returns index of record with given ID or -1.

Number ItemByValue(Column column, Variant value)
Number ItemByValue(Number id, Variant value)
Number ItemByValue(String name, Variant value)
Returns index of first record with given value of given column or -1. Column can be supplied directly or by its ID or name.

RecordSet LessOrEqualTo(Column column, Variant value)
RecordSet LessOrEqualTo(Number id, Variant value)
RecordSet LessOrEqualTo(String name, Variant value)
Returns records with values of given column less than or equal to given value. Column can be supplied directly or by its ID or name.

RecordSet LessThan(Column column, Variant value)
RecordSet LessThan(Number id, Variant value)
RecordSet LessThan(String name, Variant value)
Returns records with values of given column less than given value. Column can be supplied directly or by its ID or name.

RecordSet Matching(Column column, String pattern)
RecordSet Matching(Number id, String pattern)
RecordSet Matching(String name, String pattern)
Returns records with values of given column matching given pattern. Column can be supplied directly or by its ID or name.

RecordSet Maximum(Column column)
RecordSet Maximum(Number id)
RecordSet Maximum(String name)

Returns RecordSet object with maximum values of given column. Column can be supplied directly or by its ID or name.

Record Median(Column column)
Record Median(Number id)
Record Median(String name)

Returns Record object with median value of given column. Column can be supplied directly or by its ID or name.

RecordSet Minimum(Column column)
RecordSet Minimum(Number id)
RecordSet Minimum(String name)

Returns RecordSet object minimum value of given column. Column can be supplied directly or by its ID or name.

Number Moment(Column column, Number order)
Number Moment(Number id, Number order)
Number Moment(String name, Number order)

Returns momentum of given column. Column can be supplied directly or by its ID or name.

RecordSet NotEqualTo(Column column, Variant value)
RecordSet NotEqualTo(Number id, Variant value)
RecordSet NotEqualTo(String name, Variant value)

Returns records with values of given column not equal to given value. Column can be supplied directly or by its ID or name.

Number Range(Column column)
Number Range(Number id)
Number Range(String name)

Returns range of given column. Column can be supplied directly or by its ID or name.

Remove(Number index)
Remove(Record record)

Removes record from the record set. Removes a record from the table if the record set represents all table records. Unselects the record or removes the record from the saved selection if the record set represents the selection or a saved selection.

RemoveAll()

Removes all records from the record set. Removes all records from the table if the record set represents all table records. Unselects all records or clears the saved selection if the record set represents the selection or a saved selection.

Number Skew(Column column)
Number Skew(Number id)
Number Skew(String name)

Returns skew of given column. Column can be supplied directly or by its ID or name.

RecordSet Sort(Column column)
RecordSet Sort(Number id)
RecordSet Sort(String name)

Returns the same set of records sorted by given column. Column can be supplied directly or by its ID or name.
RecordSet SoundingLike(Column column, String text)
RecordSet SoundingLike(Number id, String text)
RecordSet SoundingLike(String name, String text)
Returns records with values of given column sounding like given text. Column can be supplied directly or by its ID or name.

Number StandardDeviation(Column column)
Number StandardDeviation(Number id)
Number StandardDeviation(String name)
Returns standard deviation of given column. Column can be supplied directly or by its ID or name.

RecordSet StartingWith(Column column, String text)
RecordSet StartingWith(Number id, String text)
RecordSet StartingWith(String name, String text)
Returns records with values of given column starting with given text. Column can be supplied directly or by its ID or name.

RecordSet StartingWithMatch(Column column, String pattern)
RecordSet StartingWithMatch(Number id, String pattern)
RecordSet StartingWithMatch(String name, String pattern)
Returns records with values of given column starting with match to given pattern. Column can be supplied directly or by its ID or name.

RecordSet StartingWithToken(Column column, String token)
RecordSet StartingWithToken(Number id, String token)
RecordSet StartingWithToken(String name, String token)
Returns records with values of given column starting with given token. Column can be supplied directly or by its ID or name.

Number Sum(Column column)
Number Sum(Number id)
Number Sum(String name)
Records sum of given column. Column can be supplied directly or by its ID or name.

RecordSet Top(Column column, Number count)
RecordSet Top(Number id, Number count)
RecordSet Top(String name, Number count)
Records given number of top records for given column. Column can be supplied directly or by its ID or name.

RecordSet Typical(Column column, Number count)
RecordSet Typical(Number id, Number count)
RecordSet Typical(String name, Number count)
Returns given number of typical records for given column. Column can be supplied directly or by its ID or name.

RecordSet Uniques(Column column)
RecordSet Uniques(Number id)
RecordSet Uniques(String name)
Returns records with unique values of given column. Column can be supplied directly or by its ID or name.

Number Variance(Column column)
Number Variance(Number id)
Number Variance(String name)
Returns variance of given column. Column can be supplied directly or by its ID or name.
Notes

Note that RecordSet.Maximum returns another RecordSet object, so to obtain the value of the maximum we would use something along the lines of:

```vbnet
Set recsetMax = recset.Maximum(field)
Set recMax = recsetMax(0)
MsgBox recMax.Data(field)
```

In earlier Manifold releases removing records in the RecordSet object representing all records in a table bound to a drawing would fail with an error message. As of 6.50 SP1, instead of failing this will remove the relevant drawing objects.

Obtained From

- RecordSet (Bottom, Containing, ContainingMatch, ContainingToken, Duplicates, DuplicatesExceptFirst, EndingWith, EndingWithMatch, EndingWithToken, EqualTo, GreaterOrEqualTo, GreaterThan, LessOrEqualTo, LessThan, Matching, Maximum, Median, Minimum, NotEqualTo, Sort, SoundingLike, StartingWith, StartingWithMatch, StartingWithToken, Top, Typical, Uniques)
- Table (RecordSet, Selection)
- TableSelectionSet (Item)

Scripting Reference
**Rect Object**

Rectangle.

**Properties**

- **Application**
  Returns application. Read only.

- **Number Area**
  Returns rectangle area. Read only.

- **Point Center**
  Sets or returns center of rectangle. Read/write.

- **Number Height**
  Returns rectangle height. Read only.

- **Any Parent**
  Returns parent object. Read only.

- **Number Width**
  Returns rectangle width. Read only.

- **Number XMax**
  Sets or returns maximum X coordinate. Read/write.

- **Number XMin**
  Sets or returns minimum X coordinate. Read/write.

- **Number YMax**
  Sets or returns maximum Y coordinate. Read/write.

- **Number YMin**
  Sets or returns minimum Y coordinate. Read/write.

**Methods**

- **Boolean ContainsPoint(Point point)**
  Returns True if rectangle contains given point and False otherwise.

- **Boolean ContainsRect(Rect rect)**
  Returns True if rectangle contains given rectangle and False otherwise.

- **Copy(Rect rect)**
  Copies given rectangle.

- **Point FitPoint(Point point)**
  Returns a copy of given point constrained by subject rectangle.

- **Rect FitRect(Rect rect)**
  Returns a copy of given rectangle constrained by subject rectangle.
Boolean Intersects(Rect rect)
Returns True if rectangle intersects given rectangle and False otherwise.

Normalize()
Normalizes coordinate pairs so that each minimum coordinate is less than or equal to corresponding maximum coordinate.

UnionPoint(Point point)
Extends rectangle to include given point.

UnionRect(Rect rect)
Extends rectangle to include given rectangle.

Scripting Reference
**RelationSet Object**
Set of table relations.

**Properties**

Application Application
Returns application. Read only.

Number Count
Returns number of relations in set. Read only.

Relation Item(Number index)
Returns relation with given index. Read only.

Relation LastAdded
Returns last added relation if any. Read only.

Any Parent
Returns parent object. Read only.

**Methods**

Add(Column column, Column columnTarget)
Appends relation with given source and target columns.

Number ItemByTableID(Number tableID)
Returns index of relation with given table ID or -1.

Remove(Number index)
Removes relation with given index.

RemoveAll()
Removes all relations.

**Obtained From**

Table (RelationSet)

Scripting Reference
RichControl Object
Rich control object.

Properties

Number Height
Sets or returns control height in pixels. Read/write.

Number Left
Sets or returns left coordinate of control in pixels. Read/write.

String Name
Sets or returns control name. Read/write.

String Tag
Sets or returns tag string associated with control. Read/write.

Number Top
Sets or returns top coordinate of control in pixels. Read/write.

Boolean Visible
Sets or returns control visibility state. Read/write.

Number Width
Sets or returns control width in pixels. Read/write.

See Also

Scripting Reference
RichForm Object
Rich form object.

Properties

Color BackColor
Sets or returns background form color. Read/write.

String Caption
Sets or returns form caption. Read/write.

Boolean Centered
Sets or returns form centering option. Read/write.

Boolean ControlBox
Sets or returns form control box option. Read/write.

Boolean Enabled
Sets or returns form enable option. Read/write.

Font Font
Sets or returns form font. Read/write.

Color ForeColor
Sets or returns foreground form color. Read/write.

Number Height
Sets or returns form height in pixels. Read/write.

Number Left
Sets or returns left coordinate of form in pixels. Read/write.

Boolean MaxButton
Sets or returns form maximize button option. Read/write.

Boolean MinButton
Sets or returns form minimize button option. Read/write.

Any Result
Sets or returns form exit code. Read/write.

String Tag
Sets or returns tag string associated with form. Read/write.

Number Top
Sets or returns top coordinate of form in pixels. Read/write.

Boolean Visible
Sets or returns form visibility state. Read/write.

Number Width
Sets or returns form width in pixels. Read/write.
Events

OnActivate()
Occurs when a form becomes the active window.

OnDblClick()
Occurs when the user presses and releases a mouse button and then presses and releases it again over a form.

OnDeactivate()
Occurs when a form is no longer the active window.

OnKeyDown(Number keyCode, Number shift)
Occurs when the user presses a key while a form has the focus.

OnKeyPress(Number keyAscii)
Occurs when the user presses and releases an ANSI key.

OnKeyUp(Number keyCode, Number shift)
Occurs when the user releases a key while a form has the focus.

OnLoad()
Occurs when a form is loaded.

OnMouseDown(Number button, Number shift, Number x, Number y)
Occurs when the user presses the mouse button while a form has the focus.

OnMouseMove(Number button, Number shift, Number x, Number y)
Occurs when the user moves the mouse.

OnMouseUp(Number button, Number shift, Number x, Number y)
Occurs when the user releases the mouse button while a form has the focus.

OnResize()
Occurs when a form is first displayed or the size of an object changes.

OnUnload()
Occurs when a form is about to be removed from the screen.

Comments

Due to potential deadlock issues, it is recommended that one clears the Result property after invoking the form if it is known to contain a reference to an object, like a Component or Application object.

Scripting Reference
Route
Route object.

Properties

Application Application
Returns application. Read only.

Geom Geom
Returns route metric. Read only.

Any Parent
Returns parent object. Read only.

Methods

AddText(String text)
Appends text to the end of the component.

String Report(Column names, TurnStyle turns)
Reports a route into string. Names column can be supplied directly or by its ID or name. If turn style parameter is omitted, the system uses TurnStyleBoth.

Obtained From

Analyzer (OptimalRoute)

Scripting Reference
**Script Object**
Script component.

**Properties**

*Application Application*
Returns application. Read only.

*Boolean Cached*
Sets or returns caching option for shared component in Enterprise Edition. Read/write.

*String Description*
Sets or returns component description. Read/write.

*Document Document*
Returns owner document. Read only.

*Folder Folder*
Sets or returns containing folder. Read/write.

*Boolean ForceSeparateThread*
Returns True if script is run in a separate thread and False otherwise, or sets that option. Read / write.

*Number ID*
Returns unique component ID. Read only.

*Boolean IsCheckedOut*
Checks if component is shared and checked out in Enterprise Edition. Read only.

*Boolean IsCheckedOutRemotely*
Checks if component is shared and checked out by another user in Enterprise Edition. Read only.

*Boolean IsModified*
Checks if component is modified since last save in Enterprise Edition. Read only.

*Boolean IsOutdated*
Checks if component is shared and there is a later version of the component on the Enterprise server in Enterprise Edition. Read only.

*Boolean IsReadOnly*
Checks if component is readonly (eg, shared and not checked out) in Enterprise Edition. Read only.

*Boolean IsShared*
Checks if component is shared on an Enterprise server in Enterprise Edition. Read only.

*Boolean IsWritable*
Checks if component is writable in Enterprise Edition. Read only.

*String Language*
Sets or returns name of script engine used to run the script (eg. "VBScript"). Read only.

*String LanguageProgID*
Sets or returns ProgID of script engine used to run the script. Read only.
Number Length
Returns number of characters in script text. Read only.

String Name
Sets or returns component name. Read/write.

String Note
Sets or returns notes associated with the component. Read/write.

ComponentSet OwnedComponentSet
Returns set of components bound to this component. Read only.

ComponentSet OwnedLayoutSet
Returns set of layouts bound to this component. Read only.

Component Owner
Returns owner component if any. Read only.

Any Parent
Returns parent object. Read only.

Number RemoteVersion
Returns version of shared component available on the Enterprise server in Enterprise Edition. Read only.

String Server
Returns server identification string for shared component in Enterprise Edition. Read only.

String ShareStatus
Returns textual report on component sharing status in Enterprise Edition. Read only.

String Text
Sets or returns script text. Read/write.

ComponentType Type
Returns component type. Read only.

String TypeName
Returns textual representation of the component type. Read only.

Number Version
Returns version of shared component within the local project in Enterprise Edition. Read only.

Methods

AddText(String text)
Appends text to the end of the component.

CheckIn()
Checks in changes made to a shared component to the Enterprise server in Enterprise Edition.

CheckOut()
Checks out a shared component for editing in Enterprise Edition.
Clear()
Clears component.

Copy()
Copies component into the Clipboard.

Cut()
Copies component into the Clipboard and then clears it.

GetLatestVersion()
Gets the latest version of a shared component from the Enterprise server in Enterprise Edition.

Boolean IsEmpty(Boolean ignoreWhiteSpaces)
Returns True if component text is empty and False otherwise.

Open()
Opens component.

OpenInNewWindow()
Opens component in new window.

Paste(Boolean replace)
Pastes the contents of the Clipboard into the component replacing previous data or adding to it. Calling the method without parameters replaces data.

Print(Boolean useDialog)
Prints component.

Run()
Runs script.

UndoCheckOut()
Undoes changes made to a shared component and gets the latest version of the component from the Enterprise server in Enterprise Edition.

Obtained From
Document (NewScript)

Scripting Reference
**Surface Object**
Surface component.

**Properties**

Application Application
Returns application. Read only.

Color BackgroundColor
Sets or returns background color. Read / write.

Rect Box
Returns bounding box of all pixels. Read only.

Boolean Cached
Sets or returns caching option for shared component in Enterprise Edition. Read/write.

ControlPointSet ControlPointSet
Returns set of control points. Read only.

CoordinateSystem CoordinateSystem
Sets or returns coordinate system. Read/write.

Boolean CoordinateSystemVerified
Checks whether or not the component coordinate system has been verified by the user, or alters the verification state. Read / write.

View DefaultView
Returns default view. Read only.

String Description
Sets or returns component description. Read/write.

Document Document
Returns owner document. Read only.

Folder Folder
Sets or returns containing folder. Read/write.

Number Height
Returns surface height in pixels. Read only.

Number ID
Returns unique component ID. Read only.

Boolean IsCheckedOut
Checks if component is shared and checked out in Enterprise Edition. Read only.

Boolean IsCheckedOutRemotely
Checks if component is shared and checked out by another user in Enterprise Edition. Read only.

Boolean IsModified
Checks if component is modified since last save in Enterprise Edition. Read only.
Boolean IsOutdated
Checks if component is shared and there is a later version of the component on the Enterprise server in Enterprise Edition. Read only.

Boolean IsReadOnly
Checks if component is readonly (eg, shared and not checked out) in Enterprise Edition. Read only.

Boolean IsShared
Checks if component is shared on an Enterprise server in Enterprise Edition. Read only.

Boolean IsWritable
Checks if component is writable in Enterprise Edition. Read only.

String LinkRowset
Returns the source rowset of a linked component. Read only.

String LinkSource
Returns the data source of a linked component. Read only.

String LinkTechnology
Returns the data access technology used by a linked component. Read only.

String Name
Sets or returns component name. Read/write.

String Note
Sets or returns notes associated with the component. Read/write.

ComponentSet OwnedComponentSet
Returns set of components bound to this component. Read only.

ComponentSet OwnedLayoutSet
Returns set of layouts bound to this component. Read only.

ComponentSet OwnedProfileSet
Returns set of profiles bound to this component. Read only.

ComponentSet OwnedTerrainSet
Returns set of terrains bound to this component. Read only.

Component Owner
Returns owner component if any. Read only.

Any Parent
Returns parent object. Read only.

PixelSet PixelSet
Returns set of surface pixels. Read only.

Number RemoteVersion
Returns version of shared component available on the Enterprise server in Enterprise Edition. Read only.
SurfaceSelectionSet SavedSelectionSet
Returns set of saved selections. Read only.

PixelSet Selection
Returns set of selected pixels. Read only.

String Server
Returns server identification string for shared component in Enterprise Edition. Read only.

String ShareStatus
Returns textual report on component sharing status in Enterprise Edition. Read only.

ComponentType Type
Returns component type. Read only.

String TypeName
Returns textual representation of the component type. Read only.

ValueType ValueType
Returns type of surface pixel values. Read only.

Number Version
Returns version of shared component within the local project in Enterprise Edition. Read only.

ViewSet ViewSet
Returns set of views associated with this component. Read only.

Number Width
Returns surface width in pixels. Read only.

Number ZoomMax
Sets or returns maximum zoom level. Read/write.

Number ZoomMin
Sets or returns minimum zoom level. Read/write.

Methods

CheckIn()
Checks in changes made to a shared component to the Enterprise server in Enterprise Edition.

CheckOut()
Checks out a shared component for editing in Enterprise Edition.

Clear(Boolean selection)
Clears entire component or selection within the component. Calling the method without parameters clears entire component.

Copy(Boolean selection)
Copies entire component or selection within the component into the Clipboard. Calling the method without parameters copies entire component.

CopyBitmap(Boolean selection)
Copies entire component or selection within the component into the Clipboard as a bitmap. Calling the method without parameters copies entire component.

Cut(Boolean selection)
Copies entire component or selection within the component into the Clipboard and then clears it. Calling the method without parameters cuts entire component.

CutBitmap(Boolean selection)
Copies entire component or selection within the component into the Clipboard as a bitmap and then clears it. Calling the method without parameters cuts entire component.

GetLatestVersion()
Gets the latest version of a shared component from the Enterprise server in Enterprise Edition.

Boolean IsLinked()
Returns True if surface is linked and False otherwise.

Open()
Opens component.

OpenInNewWindow()
Opens component in new window.

Paste(Boolean replace)
Pastes the contents of the Clipboard into the component replacing current selection or leaving it intact. Calling the method without parameters replaces selection.

ProjectTo(CoordinateSystem system, Boolean adjustResolution)
Projects component to another coordinate system. If the second parameter is True or omitted, the system automatically adjusts the local scale parameters of the coordinate system to match the current resolution of the image.

Print(Boolean useDialog)
Prints component.

RenderAreaTo(String name, Number width, Number height, Rect area, Boolean clean)
Renders component area into an image with given name, width and height. If last parameter is True, legend, north arrow and scale bar are not rendered even if they are on.

RenderTo(String name, Number width, Number height, Boolean clean)
Render component into an image with given name, width and height. If last parameter is True, legend, north arrow and scale bar are not rendered even if they are turned on.

SelectAll()
Selects all pixels.

SelectInverse()
Selects pixels that were not selected and vice versa.

SelectNone()
Unselects all pixels.

UndoCheckOut()
Undoes changes made to a shared component and gets the latest version of the component from the Enterprise server in Enterprise Edition.
Unlink()
Unlinks component. If the component is not linked, does nothing.

Obtained From
Document (NewSurface)

**SurfaceSelectionSet Object**
Set of saved selections within surface.

**Properties**

- **Application Application**
  Returns application. Read only.

- **Number Count**
  Returns number of selections in set. Read only.

- **PixelSet Item(Number index)**
  Returns selection with given index. Read only.

- **Any Parent**
  Returns parent object. Read only.

**Methods**

- **Number ItemByMask(Number mask)**
  Returns index of selection with given mask value or -1.

- **Number ItemByName(String name)**
  Returns index of selection with given name or -1.

**Obtained From**

- Surface (SavedSelectionSet)

Scripting Reference
Table Object
Table component.

Properties

Application Application
Returns application. Read only.

Boolean Cached
Sets or returns caching option for shared component in Enterprise Edition. Read/write.

ColumnSet ColumnSet
Returns set of table columns. Read only.

String Description
Sets or returns component description. Read/write.

Document Document
Returns owner document. Read only.

DSSAtomSet DSSAtomSet
Returns set of atomic expressions used in rank columns. Read only.

Folder Folder
Sets or returns containing folder. Read/write.

Number ID
Returns unique component ID. Read only.

Column Identity
Returns column used as identity. Read only.

Boolean IsCheckedOut
Checks if component is shared and checked out in Enterprise Edition. Read only.

Boolean IsCheckedOutRemotely
Checks if component is shared and checked out by another user in Enterprise Edition. Read only.

Boolean IsModified
Checks if component is modified since last save in Enterprise Edition. Read only.

Boolean IsOutdated
Checks if component is shared and there is a later version of the component on the Enterprise server in Enterprise Edition. Read only.

Boolean IsReadOnly
Checks if component is readonly (eg, shared and not checked out) in Enterprise Edition. Read only.

Boolean IsShared
Checks if component is shared on an Enterprise server in Enterprise Edition. Read only.

Boolean IsWritable
Checks if component is writable in Enterprise Edition. Read only.
DateTime LastRefreshed
Returns date and time of the last refresh for a linked component and the current date and time for a non-linked component.

String LinkRowset
Returns the source rowset of a linked component. Read only.

String LinkSource
Returns the data source of a linked component. Read only.

String LinkTechnology
Returns the data access technology used by a linked component. Read only.

String Name
Sets or returns component name. Read/write.

String Note
Sets or returns notes associated with the component. Read/write.

ComponentSet OwnedComponentSet
Returns set of components bound to this component. Read only.

ComponentSet OwnedLayoutSet
Returns set of layouts bound to this component. Read only.

Component Owner
Returns owner component if any. Read only.

Any Parent
Returns parent object. Read only.

RecordSet RecordSet
Returns set of table records. Read only.

RelationSet RelationSet
Returns set of table relations. Read only.

Number RemoteVersion
Returns version of shared component available on the Enterprise server in Enterprise Edition. Read only.

TableSelectionSet SavedSelectionSet
Returns set of saved selections. Read only.

RecordSet Selection
Returns set of selected records. Read only.

String Server
Returns server identification string for shared component in Enterprise Edition. Read only.

String ShareStatus
Returns textual report on component sharing status in Enterprise Edition. Read only.
ComponentType Type
Returns component type. Read only.

String TypeName
Returns textual representation of the component type. Read only.

Unlink()
Unlinks component. If the component is not linked, does nothing.

Number Version
Returns version of shared component within the local project in Enterprise Edition. Read only.

Methods

CheckIn()
Checks in changes made to a shared component to the Enterprise server in Enterprise Edition.

CheckOut()
Checks out a shared component for editing in Enterprise Edition.

Clear(Boolean selection)
Clears entire component or selection within the component. Calling the method without parameters clears entire component.

Copy(Boolean selection)
Copies entire component or selection within the component into the Clipboard. Calling the method without parameters copies entire component.

Cut(Boolean selection)
Copies entire component or selection within the component into the Clipboard and then clears it. Calling the method without parameters cuts entire component.

GetLatestVersion()
Gets the latest version of a shared component from the Enterprise server in Enterprise Edition.

Boolean IsLinked()
Returns True if table is linked and False otherwise.

Boolean IsNative()
Returns True if table is native and False otherwise.

Boolean IsQuery()
Returns True if table is computed by the query and False otherwise.

Open()
Opens component.

OpenInNewWindow()
Opens component in new window.

Paste(Boolean replace)
Pastes the contents of the Clipboard into the component replacing current selection or leaving it intact. Calling the method without parameters replaces selection.
Print(Boolean useDialog)
Prints component.

Boolean Refresh()
Refreshes a linked component and does nothing for a non-linked component. In the case of a linked component returns True if the refresh has succeeded and False otherwise. Refreshing a table bound to a linked drawing refreshes the drawing and vice versa.

Boolean RefreshAfter(Number)
Refreshes a linked component if the component has not been refreshed for more than the given number of seconds.

SelectAll()
Selects all records.

SelectInverse()
Selects records that were not selected and vice versa.

SelectNone()
Unselects all records.

UndoCheckOut()
Undoes changes made to a shared component and gets the latest version of the component from the Enterprise server in Enterprise Edition.

**TableSelectionSet Object**
Set of saved selections within table.

**Properties**

Application Application
Returns application. Read only.

Number Count
Returns number of selections in set. Read only.

RecordSet Item(Number index)
Returns selection with given index. Read only.

Any Parent
Returns parent object. Read only.

**Methods**

Number ItemByMask(Number mask)
Returns index of selection with given mask value or -1.

Number ItemByName(String name)
Returns index of selection with given name or -1.

**Obtained From**

Table (SavedSelectionSet)

Scripting Reference
**TableWindow Object**

Table window.

**Properties**

- **Column ActiveColumn**
  Returns active column. Read only.

- **Component ActiveComponent**
  Returns table component shown in window. Read only.

- **Record ActiveRecord**
  Records active record. Read only.

- **Application Application**
  Returns application. Read only.

- **Component Component**
  Returns table component shown in window. Read only.

- **Number Height**
  Returns window height in pixels. Read only.

- **Any Parent**
  Returns parent object. Read only.

- **Number Width**
  Returns window width in pixels. Read only.

**Methods**

- **Close()**
  Closes window.

- **Boolean HasActiveRecord()**
  Returns True if window focus is set on some record and False otherwise.

- **Boolean HasScaleInternal()**
  Returns False.

- **Refresh()**
  Updates window contents.

**Obtained From**

- **WindowSet (Item, ActiveWindow)**

**Terrain Object**
Terrain component.

**Properties**

**Application Application**
Returns application. Read only.

**Boolean Areas**
Toggles vector shapes for area objects. Read/write.

**Boolean AreaHeightColumn**
Toggles the use of a height column for area objects. Applies to vector shapes. Setting the property to True retrieves the height of each area object relative to the surface from the column named "Height". Setting the property to False sets the height of each area object relative to the surface to 0. Read/write.

**Number AreaOpacity**
Sets or returns opacity of area objects. Applies to vector shapes. Read/write.

**Boolean AreasTex**
Toggles embedding of area objects into textures. Read/write.

**Boolean AreaWalls**
Toggles vertical walls around area objects. Applies to vector shapes. Read/write.

**Color BackgroundColor**
Sets or returns background color. Read/write.

**CameraType CameraType**
Sets or returns camera type. Read/write.

**Number CloudAlpha (formerly named CloudsAlpha)**
Sets or returns cloud transparency. Read/write.

**Number CloudCount**
Sets or returns the number of clouds. Read/write.

**Number CloudHeight**
Sets or returns cloud height. Read/write.

**Boolean Clouds**
Toggles the rendering of clouds. Read/write.

**Number CloudSize**
Sets or returns cloud size in pixels. Read/write.

**String Description**
Sets or returns component description. Read/write.

**Document Document**
Returns owner document. Read only.

**Boolean Fog**
Toggles fog. Read/write.

Color FogColor
Sets or returns fog color. Read/write.

Number FogFar
Sets or returns the distance to the farthest fog clipping plane. Read/write.

Number FogNear
Sets or returns the distance to the nearest fog clipping plane. Read/write.

Folder Folder
Sets or returns containing folder. Read/write.

Number ID
Returns unique component ID. Read only.

Boolean LabelBase
Toggles base (pier) lines for label objects. Applies to vector shapes. Read/write.

Number LabelHeight
Sets or returns height of label objects. Applies to vector shapes. Read/write.

Boolean Labels
Toggles vector shapes for label objects. Read/write.

Number LabelSize
Sets or returns size of label objects. Applies to vector shapes. Read/write.

Number LabelStep
Sets or returns spacing between curved label objects in pixels. Applies to vector shapes. Read/write.

Boolean LabelsTex
Toggles embedding of label objects into textures. Read/write.

Boolean Legend
Toggles legend. Read/write.

WindowAlign LegendAlign
Sets or returns legend alignment. Read/write.

String LegendCaption
Sets or returns legend caption. Read/write.

LegendStyle LegendStyle (formerly named LegendType)
Sets or returns legend style. Read/write.

Boolean Lighting
Toggles lighting. Read/write.

Number LightingAlpha
Sets or returns lighting transparency. Read/write.
Programming Reference

LightingDirection
Sets or returns lighting direction. Read/write.

Number LightingDirX
Returns X component of lighting direction (-1, 0 or 1). Read only.

Number LightingDirY
Returns Y component of lighting direction (-1, 0 or 1). Read only.

Boolean LineBase
Toggles base (pier) lines for line objects. Applies to vector shapes. Read/write.

Number LineHeight
Sets or returns height of line objects. Applies to vector shapes. Read/write.

Boolean Lines
Toggles vector shapes for line objects. Read/write.

Number LineSize
Sets or returns size of line objects. Applies to vector shapes. Read/write.

Boolean LineSmooth
Toggles antialiasing of line objects. Applies to vector shapes. Read/write.

Boolean LinesTex
Toggles embedding of line objects into textures. Read/write.

String Name
Sets or returns component name. Read/write.

String Note
Sets or returns notes associated with the component. Read/write.

Boolean NorthArrow
Toggles north arrow. Read/write.

WindowAlign NorthArrowAlign
Sets or returns north arrow alignment. Read/write.

Color NorthArrowBackgroundColor (formerly named NorthArrowBackColor)
Sets or returns north arrow background color. Read/write.

Color NorthArrowColor (formerly named NorthArrowForeColor)
Sets or returns north arrow foreground color. Read/write.

Number NorthArrowSize
Sets or returns north arrow size in points. Read/write.

NorthArrowStyle NorthArrowStyle (formerly named NorthArrowType)
Sets or returns north arrow style. Read/write.

ComponentSet Overlay
Returns set of overlaid components. Read only.
ComponentSet OwnedComponentSet
Returns set of components bound to this component. Read only.

Component Owner
Returns owner component if any. Read only.

Any Parent
Returns parent object. Read only.

Boolean PointFrame
Toggles rectangular frames around point objects. Applies to vector shapes. Read/write.

Number PointHeight
Sets or returns height of point objects. Applies to vector shapes. Read/write.

Boolean Points
Toggles vector shapes for point objects. Read/write.

Number PointSize
Sets or returns size of point objects. Read/write.

Number PointStyle
Sets or returns style of point objects. Applies to vector shapes. Read/write.

Boolean PointsTex
Toggles embedding of point objects into textures. Read/write.

Number Quality
Sets or returns surface rendering quality. The less the number, the greater the quality with the value of 0 meaning the best quality possible. Read/write.

Number TextureOpacity
Sets or returns texture opacity. Read/write.

ComponentType Type
Returns component type. Read only.

String TypeName
Returns textual representation of the component type. Read only.

Number VisibleTiles
Sets or returns the number of visible tiles from the camera. Read/write.

Boolean Walls
Toggles vertical walls around patches of invisible pixels within the surface and at the edges of the surface. Read/write.

Boolean Water
Toggles water. Read/write.

Number WaterAlpha
Sets or returns water transparency. Read/write.
Color WaterColor
Sets or returns water color. Read/write.

Number WaterFog
Sets or returns water fog value. Read/write.

Number WaterLevel
Sets or returns water level. Read/write.

Number WaterQuality
Sets or returns water rendering quality. Read/write.

Boolean Wireframe
Toggles wireframe rendering mode. Read/write.

Number ZScale
Sets or returns Z scale factor. Read/write.

Methods

Copy()
Copies component into the Clipboard.

Open()
Opens component.

OpenInNewWindow()
Opens component in new window.

Paste()
Pastes the contents of the Clipboard into the component replacing previous data.

Print(Boolean useDialog)
Prints component.

RenderTo(String name, Number x, Number y, Number cameraX, Number cameraY, Number cameraZ, Number cameraDX, Number cameraDY, Number cameraDZ)
Render component into an image with given name, width and height, using given location and direction of the camera. The last three parameters which give the direction of the camera can be omitted.

Obtained From

Document (NewTerrain)

See Also

Scripting Reference
TerrainWindow Object
Terrain window.

Properties

Component ActiveComponent
Returns terrain component shown in window. Read only.

Application Application
Returns application. Read only.

Number CameraDX
Sets or returns X direction of a camera. Read/write.

Number CameraDY
Sets or returns Y direction of a camera. Read/write.

Number CameraDZ
Sets or returns Z direction of a camera. Read/write.

Number CameraHeight
Sets or returns camera height. Read/write.

Component Component
Returns terrain component shown in window. Read only.

Number Height
Returns window height in pixels. Read only.

Point Location
Sets or returns viewport center. Read/write.

Point LocationLatLon
Sets or returns viewport center in lat/lon coordinates. Read/write.

Any Parent
Returns parent object. Read only.

Number SurfaceHeight
Returns height of surface at current camera location. Read only.

Number Width
Returns window width in pixels. Read only.

Methods

Close()
Closes window.

Boolean HasLocation()
Returns True.
Boolean HasScale()
  Returns False.

Boolean HasScaleInternal()
  Returns False.

MoveTo(Branch branch)
MoveTo(BranchSet branchSet)
MoveTo(Component component)
MoveTo(Geom geom)
MoveTo(Label label)
MoveTo(LabelSet labelSet)
MoveTo(Object object)
MoveTo(ObjectSet objectSet)
MoveTo(Pixel pixel)
MoveTo(PixelSet pixelSet)
MoveTo(Point point)
MoveTo(PointSet pointSet)
MoveTo(Rect rect)
  Centers viewport on given object or set of objects. Branches, geoms, points, rects and their sets are assumed to be in the coordinate system of the displayed component.

MoveToLocation(Point point, Boolean latLon)
  Centers viewport on given location. The last parameter is optional.

Refresh()
  Updates window contents.

RenderTo(String name)
  Renders window into an image with given name.

Obtained From

WindowSet (Item, ActiveWindow)

Scripting Reference
Theme Object
Theme component.

Properties

Application Application
Returns application. Read only.

Format AreaBackground
Returns background color used for areas. Read only.

Format AreaBorderBackground
Returns border background color used for areas. Read only.

Format AreaBorderForeground
Returns border foreground color used for areas. Read only.

Format AreaBorderSize
Returns border size used for areas. Read only.

Format AreaBorderStyle
Returns border style used for areas. Read only.

Format AreaForeground
Returns foreground color used for areas. Read only.

Format AreaSize
Returns size used for areas. Read only.

Format AreaStyle
Returns style used for areas. Read only.

Color BackgroundColor
Sets or returns background color. Read / write.

Boolean Cached
Sets or returns caching option for shared component in Enterprise Edition. Read/write.

ControlPointSet ControlPointSet
Returns set of control points of parent drawing. Read only.

CoordinateSystem CoordinateSystem
Sets or returns coordinate system of parent drawing. Read/write.

Boolean CoordinateSystemVerified
Checks whether or not the component coordinate system has been verified by the user, or alters the verification state. Read / write.

View DefaultView
Returns default view of parent drawing. Read only.

String Description
Sets or returns component description. Read/write.
Document
  Returns owner document. Read only.

Number Epsilon
  Sets or returns location precision of parent drawing. Read/write.

Folder Folder
  Sets or returns containing folder. Read/write.

Number ID
  Returns unique component ID. Read only.

Boolean IsCheckedOut
  Checks if component is shared and checked out in Enterprise Edition. Read only.

Boolean IsCheckedOutRemotely
  Checks if component is shared and checked out by another user in Enterprise Edition. Read only.

Boolean IsModified
  Checks if component is modified since last save in Enterprise Edition. Read only.

Boolean IsOutdated
  Checks if component is shared and there is a later version of the component on the Enterprise server in Enterprise Edition. Read only.

Boolean IsReadOnly
  Checks if component is readonly (eg, shared and not checked out) in Enterprise Edition. Read only.

Boolean IsShared
  Checks if component is shared on an Enterprise server in Enterprise Edition. Read only.

Boolean IsWritable
  Checks if component is writable in Enterprise Edition. Read only.

DateTime LastRefreshed
  Returns date and time of the last refresh for a linked parent drawing and the current date and time for a non-linked parent drawing.

Format LineBackground
  Returns background color used for lines. Read only.

Format LineForeground
  Returns foreground color used for lines. Read only.

Format LineSize
  Returns size used for lines. Read only.

Format LineStyle
  Returns style used for lines. Read only.

String Name
  Sets or returns component name. Read/write.
String Note
Sets or returns notes associated with the component. Read/write.

ObjectSet ObjectSet
Returns set of objects in parent drawing. Read only.

ComponentSet OwnedComponentSet
Returns set of components bound to this component. Read only.

ComponentSet OwnedLayoutSet
Returns set of layouts bound to this component. Read only.

Drawing OwnerDrawing
Returns parent drawing. Read only.

Component Owner
Returns parent drawing. Read only.

Any Parent
Returns parent object. Read only.

Format PointBackground
Returns background color used for points. Read only.

Format PointForeground
Returns foreground color used for points. Read only.

Format PointRotation
Returns rotation used for points. Read only.

Format PointSize
Returns size used for points. Read only.

Format PointStyle
Returns style used for points. Read only.

Number RemoteVersion
Returns version of shared component available on the Enterprise server in Enterprise Edition. Read only.

DrawingSelectionSet SavedSelectionSet
Returns set of saved selections in parent drawing. Read only.

ObjectSet Selection
Returns set of selected objects in parent drawing. Read only.

String Server
Returns server identification string for shared component in Enterprise Edition. Read only.

String ShareStatus
Returns textual report on component sharing status in Enterprise Edition. Read only.

ComponentType Type
Returns component type. Read only.

String TypeName
Returns textual representation of the component type. Read only.

Number Version
Returns version of shared component within the local project in Enterprise Edition. Read only.

ViewSet ViewSet
Returns set of views associated with parent drawing. Read only.

Number ZoomMax
Sets or returns maximum zoom level. Read/write.

Number ZoomMin
Sets or returns minimum zoom level. Read/write.

Number ZoomRender
Sets or returns render zoom level. Read/write.

Methods

CheckIn()
Checks in changes made to a shared component to the Enterprise server in Enterprise Edition.

CheckOut()
Checks out a shared component for editing in Enterprise Edition.

Clear(Boolean selection)
Clears entire component or selection within the component. Calling the method without parameters clears entire component.

Copy(Boolean selection)
Copies entire component or selection within the component into the Clipboard. Calling the method without parameters copies entire component.

Cut(Boolean selection)
Copies entire component or selection within the component into the Clipboard and then clears it. Calling the method without parameters cuts entire component.

GetLatestVersion()
Gets the latest version of a shared component from the Enterprise server in Enterprise Edition.

Boolean IsEmpty()
Returns True if parent drawing contains no objects and False otherwise.

Boolean IsLinked()
Returns True if parent drawing is linked and False otherwise.

Open()
Opens component.

OpenInNewWindow()
Opens component in new window.
Paste(Boolean replace)
  Pastes the contents of the Clipboard into the component replacing current selection or leaving it intact. Calling the method without parameters replaces selection.

ProjectTo(CoordinateSystem system)
  Projects parent drawing to another coordinate system.

Print(Boolean useDialog)
  Prints component.

RenderAreaTo(String name, Number width, Number height, Rect area, Boolean clean)
  Renders component area into an image with given name, width and height. If last parameter is True, legend, north arrow and scale bar are not rendered even if they are on.

RenderTo(String name, Number width, Number height, Boolean clean)
  Render component into an image with given name, width and height. If last parameter is True, legend, north arrow and scale bar are not rendered even if they are turned on.

Boolean Refresh()
  Refreshes a linked parent drawing and does nothing for a non-linked parent drawing. In the case of a linked parent drawing returns True if the refresh has succeeded and False otherwise. Refreshing a table bound to a linked drawing refreshes the drawing and vice versa.

Boolean RefreshAfter(Number)
  Refreshes a linked parent drawing if it has not been refreshed for more than the given number of seconds.

UndoCheckOut()
  Undoes changes made to a shared component and gets the latest version of the component from the Enterprise server in Enterprise Edition.

Scripting Reference
**Topology Object**
Topology data. To use the object, first bind it to a particular drawing using the Bind method.

**Properties**

Application Application
Returns application. Read only.

Drawing Drawing
Returns bound drawing. Read only.

Number Epsilon
Returns location precision of the bound drawing at the time topology data was created. Read only.

Any Parent
Returns parent object. Read only.

Number Version
Returns a numeric value representing the version of the geometry in the bound drawing at the time topology data was created. Read only.

**Methods**

Bind(Drawing drawing)
Binds topology object to drawing.

Build()
Builds topology for the bound drawing. If the drawing contains areas, builds topology for areas and ignores lines and points. If the drawing contains no areas but contains lines, builds topology for lines and ignores points.

DoIdentity(Topology overlay, String name)
Performs an "identity" topology overlay and saves resulting data to a new drawing. Overlaid topology should contain data for areas.

DoIntersect(Topology overlay, String name)
Performs an "intersect" topology overlay and saves resulting data to a new drawing. Both topology objects should contain data for areas.

DoUnion(Topology overlay, String name)
Performs a "union" topology overlay and saves resulting data to a new drawing. Both topology objects should contain data for areas.

DoUpdate(Topology overlay, String name)
Performs an "update" topology overlay and saves resulting data to a new drawing. Both topology objects should contain data for areas.

Boolean IsCompatibleWith(Topology overlay)
Returns True if performing a topology overlay with given topology object will use topology data cached in that object, and False if performing a topology overlay will rebuild topology from scratch. Two topology objects are only compatible with each other if their drawings are in the same coordinate system and use the same location precision.

Boolean IsUpToDate(String filename)
Returns True if topology stored in given file is valid and up to date with the current version of the bound drawing and false otherwise.
Load(String filename)
   Loads topology data from given file.

Output(String name)
   Rebuilds objects in the bound drawing using created topology data and saves resulting objects to a new
drawing.

Save(String filename)
   Saves topology data to given file. If the file already exists, it will be overwritten.

**TriangleSet Object**
Set of triangles. Each triangle is identified by three vertex indices.

**Properties**

**Application Application**
Returns application. Read only.

**Array Indices**
Returns an array of vertex indices. Elements 0, 1 and 2 identify vertices for the first triangle, elements 3, 4 and 5 identify vertices for the second triangle, and so on. Read only.

**Any Parent**
Returns parent object. Read only.

**Array Xs**
Returns an array of X coordinates for vertices. Read only.

**Array Ys**
Returns an array of Y coordinates for vertices. Read only.

**Obtained From**

**Geom** (DecomposeToTrianglesAdv)

**See Also**

Unit Object
Coordinate system unit.

Properties

Application
Application
Returns application. Read only.

String Name
Returns unit name. Read only.

String NickName
Returns unit nick name. Read only.

String NickNameArea
Returns unit nick name for area measurements. Read only.

Any Parent
Returns parent object. Read only.

Number Scale
Returns unit scale with respect to degree or meter. Read only.

Methods

Boolean IsLatLon()
Returns True for angular units and False for metric units.

Load(String name)
Loads unit using given name.

Obtained From

Application (DefaultUnit, DefaultUnitLatLon, NewUnit)
LayoutEntry (BorderUnit)
UnitSet (Item)

See Also

Scripting Reference
UnitSet Object
Set of units.

Properties

Application Application
Returns application. Read only.

Number Count
Returns number of units in set. Read only.

Unit Item(Number index)
Unit Item(String name)
Returns unit with given index or name. Read only.

Any Parent
Returns parent object. Read only.

Methods

Number ItemByAnyName(String name)
Returns index of unit with given name, nick name or area nick name, or -1.

Number ItemByName(String name)
Returns index of unit with given name or -1.

Number ItemByNickName(String name)
Returns index of unit with given nick name or -1.

Number ItemByNickNameArea(String name)
Returns index of unit with given area nick name or -1.

Obtained From

Application (UnitSet)

Scripting Reference
**UserInterface Object**

User interface manager. Allows invoking commands and accessing user interface elements such as dialogs and controls. Scripting the user interface requires that the script is run in a separate thread.

**Properties**

- **Application**
  - Returns application. Read only.

- **Boolean DisplaysModalDialog**
  - Returns True if user interface displays a modal dialog. Read only.

- **UserInterfaceDialog ModalDialog**
  - Returns topmost modal dialog. Read only.

- **Any Parent**
  - Returns parent object. Read only.

- **UserInterfaceDialogSet Panes**
  - Returns panes. Panes can be accessed by names. Read only.

- **UserInterfaceDialogSet Toolbars**
  - Returns toolbars owned by the main window. Individual toolbars can be accessed by names. Read only.

**Methods**

- **InvokeCommand(String name, String context)**
  - Invokes command with given name. To see the names of available commands, launch Manifold from the command line specifying the "clist" command line option. The context parameter is optional. If supplied, it uses one of the following patterns:

  - "cell:<rowNumber>:<columnName>" - executes command in the context of the table cell in the specified column and row in the active table window,

  - "column:<columnName>" - executes command in the context of the specified column in the active table window,

  - "element:<elementID>" - executes command in the context of the specified layout element in the active layout window,

  - "label:<labelID>" - executes command in the context of the specified label in the active labels window or map window,

  - "layer:<layerName>" - executes command in the context of the specified layer in the active map window,

  - "object:<objectId>" - executes command in the context of the specified drawing object in the active drawing window or map window,

  - "pane:<paneName>" - executes command in the context of the specified pane,

  - "row:<rowNumber>" - executes command in the context of the specified row in the active table window.

Scripting Reference
UserInterfaceControl Object
A user interface control, for example, a button or a combo box. A control can contain items.

Properties

Application Application
- Returns application. Read only.

Boolean Checked
- Sets or returns the check state. Read / write.

Boolean Enabled
- Returns True if control is enabled and False otherwise. Read only.

UserInterfaceControlItemSet ItemSet
- Returns control items. Read only.

String Name
- Returns control name. Read only.

Any Parent
- Returns parent object. Read only.

String Text
- Sets or returns control text. Read / write.

Method

Push()
- Simulates clicking on a push button.

PushNamed(String name)
- Push the specified button in the drop-down portion of the control. Used with color, size, and style wells whose drop-down portions contain buttons for thematic formatting ("Theme") and with similar windows.

Obtained From

UserInterfaceControlSet (Item)

Scripting Reference
UserInterfaceControlItem Object
An item within a user interface control, for example, in a list view or a tree view. An item can contain other items.

Properties

Application Application
Returns application. Read only.

Boolean Checked
Sets or returns the check state. Read / write.

Any Parent
Returns parent object. Read only.

UserInterfaceControlItemSet SubitemSet
Returns subitems. Read only.

String Text
Returns item text. Read only.

String Value
Gets or sets item value. Read / write.

Scripting Reference
**UserInterfaceControlItemSet Object**
Set of items within a user interface control, for example, a list view or a tree view.

**Properties**

Application Application
Returns application. Read only.

Number Count
Returns number of items in set. Read only.

UserInterfaceControlItem Item(Number index)  UserInterfaceControlItem Item(String text)
Returns item with given index or text. Read only.

Any Parent
Returns parent object. Read only.

**Methods**

Number ItemByName(String text)
Returns index of item with given text or -1.

**Obtained From**

UserInterfaceControl (ItemSet)
UserInterfaceControlItem (SubitemSet)

**See Also**

Scripting Reference
UserInterfaceControlSet Object
Set of user interface controls, for example, in a dialog.

Properties

Application Application
Returns application. Read only.

Number Count
Returns number of controls in set. Read only.

UserInterfaceControl Item(Number index) UserInterfaceControl Item(String name)
Returns control with given index or name. Read only.

Any Parent
Returns parent object. Read only.

Methods

Number ItemBy_Name(String name)
Returns index of control with given name or -1.

Obtained From

UserInterfaceDialog (ControlSet)

See Also

Scripting Reference
UserInterfaceDialog Object
User interface dialog.

Properties

Application Application
Returns application. Read only.

String Caption
Returns dialog caption. Read only.

UserInterfaceControlSet ControlSet
Returns dialog controls. Read only.

Any Parent
Returns parent object. Read only.

Methods

Accept()
Accepts dialog as though the user has pressed OK or similar button.

Cancel()
Cancels dialog as though the user has pressed Cancel.

Obtained From

UserInterface (ModalDialog)
UserInterfaceDialogSet (Item)

See Also

Scripting Reference
**UserInterfaceDialogSet Object**
Set of dialogs.

**Properties**

Application Application
Returns application. Read only.

Number Count
Returns number of dialogs in set. Read only.

UserInterfaceDialog Item(Number index)
UserInterfaceDialog Item(String name)
Returns dialog with given index or name. Read only.

Any Parent
Returns parent object. Read only.

**Methods**

Number ItemByName(String name)
Returns index of dialog with given name or -1.

**Obtained From**

UserInterface (Panels)

**See Also**

Scripting Reference
Version Object
Version information.

Properties

Application
Returns application. Read only.

Number Build
Returns build number. Read only.

String Edition
Returns edition string. Read only.

Number Major
Returns major version number. Read only.

Number Minor
Returns minor version number. Read only.

Boolean Prerelease
Returns True if application is a prerelease (beta) version and False otherwise. Read only.

Number ServicePack
Returns service pack number. Read only.

Any Parent
Returns parent object. Read only.

Obtained From

Application (Version)

See Also

Scripting Reference
View Object
Component view.

Properties

Application Application
Returns application. Read only.

Point Center
Sets or returns center of view in native coordinates. Read/write.

Component Component
Returns owner component. Read only.

String Name
Sets or returns view name. Read/write.

Any Parent
Returns parent object. Read only.

Number Scale
Sets or returns view scale with respect to current coordinate system. Read/write.

Number ScaleAbsolute
Sets or returns view scale. Read/write.

Obtained From

Application (NewView)
Drawing (DefaultView)
Image (DefaultView)
Labels (DefaultView)
Map (DefaultView)
Surface (DefaultView)
ViewSet (Item, LastAdded)
Zones (DefaultView)

See Also

Scripting Reference
ViewSet Object
Set of views.

Properties

Application Application
Returns application. Read only.

Number Count
Returns number of views in set. Read only.

View Item(Number index)
View Item(String name)
Returns view with given index or name. Read only.

View LastAdded
Returns last added view if any. Read only.

Any Parent
Returns parent object. Read only.

Methods

Add(View view)
Appends view to set.

Number ItemByName(String name)
Returns index of view with given name or -1.

Remove(Number index)
Removes view with given index.

RemoveAll()
Removes all views.

Obtained From

Drawing (ViewSet)
Image (ViewSet)
Labels (ViewSet)
Map (ViewSet)
Surface (ViewSet)
Zones (ViewSet)

See Also

Scripting Reference
**Window Object**

Generic window.

**Properties**

Component ActiveComponent
Returns active component shown in window. Read only.

Application Application
Returns application. Read only.

Rect Bounds
Returns the area covered by the window, in the coordinate system of the displayed component. Read only.

Component Component
Returns component shown in window. Read only.

Number Height
Returns window height in pixels. Read only.

Any Parent
Returns parent object. Read only.

Number Scale
Sets or returns viewport scale (projected components only). Read/write.

Number ScaleInternal
Sets or returns internal pixel-to-data ratio. Read/write.

Number Width
Returns window width in pixels. Read only.

**Methods**

Close()
Closes window.

Point GetLocation(Boolean latLon)
Returns viewport center. LatLon parameter is optional.

Boolean HasLocation()
Returns True if viewport center can be modified and False otherwise.

Boolean HasScale()
Returns True if viewport scale can be obtained or modified and False otherwise.

Boolean HasScaleInternal()
Returns True if internal pixel-to-data ratio can be obtained or modified and False otherwise.

MoveTo(Branch branch)
MoveTo(BranchSet branchSet)
MoveTo(Component component)
MoveTo(Geom geom)
MoveTo(Label label)
MoveTo(LabelSet labelSet)
MoveTo(Object object)
MoveTo(ObjectSet objectSet)
MoveTo(Pixel pixel)
MoveTo(PixelSet pixelSet)
MoveTo(Point point)
MoveTo(PointSet pointSet)
MoveTo(Rect rect)
Centers viewport on given object or set of objects. Branches, geoms, points, rects and their sets are assumed to be in the coordinate system of the displayed component.

MoveToLocation(Point point, Boolean latLon)
Centers viewport on given location. LatLon parameter is optional.

Refresh()
Updates window contents.

RenderTo(String name)
Renders window into an image with given name.

ZoomTo(Branch branch)
ZoomTo(BranchSet branchSet)
ZoomTo(Component component)
ZoomTo(Geom geom)
ZoomTo(Label label)
ZoomTo(LabelSet labelSet)
ZoomTo(Object object)
ZoomTo(ObjectSet objectSet)
ZoomTo(Pixel pixel)
ZoomTo(PixelSet pixelSet)
ZoomTo(Point point)
ZoomTo(PointSet pointSet)
ZoomTo(Rect rect)
Zooms to given object or set of objects. Branches, geoms, points, rects and their sets are assumed to be in the coordinate system of the displayed component. If the bounding box of the object is a point (for example, if the object is a point), centers viewport on given object.
WindowSet Object
Set of windows.

Properties

Window ActiveWindow
Returns active window. Read only.

Application Application
Returns application. Read only.

Number Count
Returns number of windows in set. Read only.

Window Item(Number index)
Returns window with given index. Read only.

Any Parent
Returns parent object. Read only.

Methods

Close()
Closes all windows in set.

Obtained From

Application (WindowSet)

See Also

Scripting Reference
Zone Object
Zone.

Properties

Application Application
Returns application. Read only.

Number Area
Returns zone area. Read only.

ZoneSet Children
Returns set of direct children of zone. Read only.

String Name
Returns name of zone. Read only.

Any Parent
Returns parent object. Read only.

Zone ParentZone
Returns parent zone. Read only

String Path
Returns path to zone. Read only.

Obtained From

Zone (ParentZone)
ZoneSet (Item)

See Also

Scripting Reference
**Zones Object**
Zones component.

**Properties**

**Application Application**
Returns application. Read only.

**ControlPointSet ControlPointSet**
Returns set of control points. Read only.

**CoordinateSystem CoordinateSystem**
Sets or returns coordinate system. Read/write.

**View DefaultView**
Returns default view. Read only.

**String Description**
Sets or returns component description. Read/write.

**Document Document**
Returns owner document. Read only.

**Folder Folder**
Sets or returns containing folder. Read/write.

**Number ID**
Returns unique component ID. Read only.

**String Name**
Sets or returns component name. Read/write.

**String Note**
Sets or returns notes associated with the component. Read/write.

**Component Owner**
Returns owner component if any. Read only.

**Any Parent**
Returns parent object. Read only.

**ZoneSelectionSet SavedSelectionSet**
Returns set of saved selections. Read only.

**ZoneSet Selection**
Returns set of selected zones. Read only.

**ComponentType Type**
Returns component type. Read only.

**String TypeName**
Returns textual representation of the component type. Read only.
ViewSet ViewSet
Returns set of views associated with this component. Read only.

Number ZoomMax
Sets or returns maximum zoom level. Read/write.

Number ZoomMin
Sets or returns minimum zoom level. Read/write.

ZoneSet ZoneSet
Returns set of zones. Read only.

**Methods**

Boolean IsEmpty()
Returns True if component contains no zones and False otherwise.

Open()
Opens component.

OpenInNewWindow()
Opens component in new window.

Print(Boolean useDialog)
Prints component.

**Obtained From**

Document (NewZones)

**See Also**

Scripting Reference
ZoneSelectionSet Object
Set of saved selections within zones.

Properties

Application Application
Returns application. Read only.

Number Count
Returns number of selections in set. Read only.

ZoneSet Item(Number index)
Returns selection with given index. Read only.

Any Parent
Returns parent object. Read only.

Methods

Number ItemByMask(Number mask)
Returns index of selection with given mask value or -1.

Number ItemByName(String name)
Returns index of selection with given name or -1.

Obtained From

Zones (SavedSelectionSet)

See Also

Scripting Reference
ZoneSet Object
Set of zones.

Properties

Application Application
Returns application. Read only.

Number Count
Returns number of zones in set. Read only.

Zone Item(Number index)
Returns zone with given index. Read only.

Any Parent
Returns parent object. Read only.

Obtained From

Zone (Children)
Zones (Selection, ZoneSet)
ZoneSelectionSet (Item)

Control Constants
ControlAlignment Constants
Control alignment options.

Values

wlLeft
Left alignment.

wlRight
Right alignment.

See Also

Scripting Reference
ControlAlignmentText Constants
Control text alignment options.

Values

wlCenter
Text is centered.

wlLeftJustify
Text is justified to the left side.

wlRightJustify
Text is justified to the right side.

See Also

Scripting Reference
ControlAppearance Constants

Control appearance options.

Values

wl3D
Control is displayed with 3D effect.

wlFlat
Control is displayed flat.

See Also

Scripting Reference
ControlBorderStyle Constants
Control border styles.

Values

wlFixedSingle
Control has single-line border.

wlNone
Control has no border.

See Also

Scripting Reference
ControlCheckValue Constants
Control check values.

Values

wlChecked
Control is checked.

wlGrayed
Control is grayed (neither checked nor unchecked).

wlUnchecked
Control is unchecked.

See Also

Scripting Reference
ControlMouseButton Constants
Mouse buttons recognized by component control.

Values

MouseButtonExtended1
First extended button.

MouseButtonExtended2
Second extended button.

MouseButtonLeft
Left button.

MouseButtonMiddle
Middle button.

MouseButtonNone
None.

MouseButtonRight
Right button.

See Also

Scripting Reference
ControlMouseMode Constants
Mouse modes supported by component control.

Values

ControlMouseModeNone
None.

ControlMouseModeCenter
Center.

ControlMouseModeGenericArea
Area. Uses BeginTrack and EndTrack events.

ControlMouseModeGenericAreaFreeform
Freeform area. Uses BeginTrack and EndTrack events.

ControlMouseModeGenericBox
Box. Uses BeginTrack and EndTrack events.

ControlMouseModeGenericBoxCenter
Box tracked from center. Uses BeginTrack and EndTrack events.

ControlMouseModeGenericCircle
Circle. Uses BeginTrack and EndTrack events.

ControlMouseModeGenericCircleBox
Circle tracked with a box. Uses BeginTrack and EndTrack events.

ControlMouseModeGenericCircleCenter
Circle tracked from center. Uses BeginTrack and EndTrack events.

ControlMouseModeGenericCircleDiameter
Circle tracked with a diameter. Uses BeginTrack and EndTrack events.

ControlMouseModeGenericLine
Line. Uses BeginTrack and EndTrack events.

ControlMouseModeGenericLineFreeform
Freeform line. Uses BeginTrack and EndTrack events.

ControlMouseModeGenericPoint
Point. Uses BeginTrack and EndTrack events.

ControlMouseModeGrabber
Grabber.

ControlMouseModeTracker
Tracker (measures distances and areas).

ControlMouseModeZoomBox
Zoom box.
ControlMouseModeZoomIn
Zoom in.

ControlMouseModeZoomOut
Zoom out.

See Also

Scripting Reference
ControlMousePointer Constants
Control mouse pointers.

Values

wlArrow
Arrow pointer.

wlArrowHourglass
Arrow with hourglass pointer.

wlArrowQuestion
Arrow with question pointer.

wlCross
Cross (precision selection) pointer.

wlCustom
Custom pointer.

wlDefault
Default pointer.

wlHourglass
Hourglass pointer.

wlBeam
I-beam (text editing) pointer.

wlIcon
Icon pointer.

wlNoDrop
“No-drop” pointer.

wlSize
Four arrow sizing pointer.

wlSizeAll
Four arrow sizing pointer.

wlSizeEW
Horizontal sizing pointer.

wlSizeNESW
Diagonal sizing pointer.

wlSizeNS
Vertical sizing pointer.

wlSizeNWSE
Diagonal sizing pointer.
wlUpArrow
Up arrow pointer.

Scripting Reference
**ControlMultiSelect Constants**
Control multiple selection options.

**Values**

- **wlExtended**
  Multiple selection is enabled. The user can select items by holding mouse button and dragging the cursor.

- **wlNoMultiSelect**
  Multiple selection is disabled.

- **wlSimple**
  Multiple selection is enabled.

**See Also**

Scripting Reference
ControlOleDrag Constants
Control OLE drag options.

Values

wlOLEDragAutomatic
Dragging is done in automatic mode.

wlOLEDragManual
Dragging is done in manual mode.

See Also

Scripting Reference
**ControlOleDrop Constants**
Control OLE drop options.

**Values**

- `wlOLEDropAutomatic`
  Dropping is done in automatic mode.

- `wlOLEDropManual`
  Dropping is done in manual mode.

- `wlOLEDropNone`
  Control does not support dropping.

**See Also**

Scripting Reference
ControlScrollBars Constants
Control scroll bar options.

Values

wlBoth
Control has both horizontal and vertical scroll bars.

wlHorizontal
Control has horizontal scroll bar.

wlNoScrollBars
Control has no scroll bars.

wlVertical
Control has vertical scroll bar.

See Also

Scripting Reference
**ControlStyle Constants**

Control styles.

**Values**

- **wlGraphical**
  Control is in graphical style and displays pictures.

- **wlStandard**
  Control is in standard style.

**See Also**

Scripting Reference
**ControlStyleCombo Constants**

Combo box control styles.

**Values**

wlDropdownCombo
Control has an edit portion and a list portion.

wlDropdownList
Control has an edit portion and a list portion. The edit portion can only display items from the list portion.

wlSimple
Control has an edit portion and a list portion that is always visible.

**See Also**

Scripting Reference
ControlStyleList Constants
List box control styles.

Values

wlCheckbox
Each control item has a checkbox near it.

wlStandard
Standard style.

See Also
Scripting Reference
Control Objects
Check Control
Check box control.

Properties

ControlAlignment Alignment
Sets or returns control alignment option. Read/write.

ControlAppearance Appearance
Sets or returns control appearance option. Read/write.

Number BackColor
Sets or returns background color. Read/write.

String Caption
Sets or returns control caption. Read/write.

Picture DisabledPicture
Sets or returns a graphic to be displayed when control is disabled. Read/write.

Picture DownPicture
Sets or returns a graphic to be displayed when control is pushed. Read/write.

Boolean Enabled
Sets or returns enabled option. Read/write.

Font Font
Sets or returns control font. Read/write.

Boolean FontBold
Sets or returns bold option of control font. Read/write.

Boolean FontItalic
Sets or returns italic option of control font. Read/write.

String FontName
Sets or returns facename of control font. Read/write.
Number FontSize
Sets or returns size of control font in points. Read/write.

Boolean FontStrikethru
Sets or returns strikethrough option of control font. Read/write.

Boolean FontUnderline
Sets or returns underline option of control font. Read/write.

Number ForeColor
Sets or returns foreground color. Read/write.

Number MaskColor
Sets or returns transparent color used in pictures. Read/write.

Picture MouseIcon
Sets or returns custom mouse icon. Read/write.

ControlMousePointer MousePointer
Sets or returns type of mouse pointer displayed over a control. Read/write.

ControlOleDrop OLEDropMode
Sets or returns OLE drop mode option. Read/write.

Picture Picture
Sets or returns a graphic to be displayed when control is up. Read/write.

Boolean RightToLeft
Sets or returns text display direction on a bidirectional system. Read/write.

ControlStyle Style
Sets or returns control style. Read/write.

Boolean UseMaskColor
Sets or returns transparent color option. Read/write.

ControlCheckValue Value
Sets or returns control value. Read/write.

**Methods**

OLEDrag()
Starts an OLE drag/drop event with given control as the source.

Refresh()
Forces a complete repaint of control.

**Events**

Click()
Occurs when the user clicks a control.
KeyDown(Number keyCode, Number shift)
Occurs when the user presses a key while a control has focus.

KeyPress(Number keyAscii)
Occurs when the user presses and releases an ANSI key.

KeyUp(Number keyCode, Number shift)
Occurs when the user releases a key while a control has focus.

MouseDown(Number button, Number shift, Number x, Number y)
Occurs when the user presses the mouse button over a control.

MouseMove(Number button, Number shift, Number x, Number y)
Occurs when the user moves the mouse.

MouseUp(Number button, Number shift, Number x, Number y)
Occurs when the user releases the mouse button.

See Also

Scripting Reference
Combo Control
Combo box control.

Properties

ControlAppearance Appearance
Sets or returns control appearance option. Read/write.

Number BackColor
Sets or returns background color. Read/write.

Boolean Enabled
Sets or returns enabled option. Read/write.

Font Font
Sets or returns control font. Read/write.

Boolean FontBold
Sets or returns bold option of control font. Read/write.

Boolean FontItalic
Sets or returns italic option of control font. Read/write.

String FontName
Sets or returns facename of control font. Read/write.

Number FontSize
Sets or returns size of control font in points. Read/write.

Boolean FontStrikethru
Sets or returns strikethrough option of control font. Read/write.

Boolean FontUnderline
Sets or returns underline option of control font. Read/write.

Number ForeColor
Sets or returns foreground color. Read/write.

Boolean IntegralHeight
Sets or returns integral height option. Value of false indicates that control displays partial items. Read/write.

Number ItemData(Number index)
Sets or returns a number associated with given control item. Read/write.

String List(Number index)
Sets or returns text of given control item. Read/write.

Number ListCount
Sets or returns number of items in control. Read/write.

Number ListIndex
Sets or returns index of currently selected control item. Read/write.
Boolean Locked
Sets or returns control locking option. Locked controls cannot be edited. Read/write.

Picture MouseIcon
Sets or returns custom mouse icon. Read/write.

ControlMousePointer MousePointer
Sets or returns type of mouse pointer displayed over a control. Read/write.

Number NewIndex
Sets or returns index of most recently added control item. Read/write.

ControlOleDrag OLEDragMode
Sets or returns OLE drag mode option. Read/write.

ControlOleDrop OLEDropMode
Sets or returns OLE drop mode option. Read/write.

Boolean RightToLeft
Sets or returns text display direction on a bidirectional system. Read/write.

Number SelLength
Sets or returns number of characters in text selection. Read/write.

Number SelStart
Sets or returns starting point of text selection. Read/write.

String SelText
Sets or returns text selection. Read/write.

Boolean Sorted
Sets or returns sorted control option. Read/write.

ControlStyleCombo Style
Sets or returns control style. Read/write.

String Text
Sets or returns the text contained in control. Read/write.

Number TopIndex
Sets or returns index of topmost control item. Read/write.

Methods

Number AddItem(String item)
Appends new control item and returns its index.

Clear()
Removes all control items.

OLEDrag()
Starts an OLE drag/drop event with given control as the source.
Refresh()
Forces a complete repaint of control.

RemoveItem(Number index)
Removes item with given index.

Events

Change()
Occurs when the contents of a control has changed.

Click()
Occurs when the user clicks a control.

DbClick()
Occurs when the user doubleclicks a control.

DropDown()
Occurs when the list portion of a control is about to drop down.

KeyDown(Number keyCode, Number shift)
Occurs when the user presses a key while a control has focus.

KeyPress(Number keyAscii)
Occurs when the user presses and releases an ANSI key.

KeyUp(Number keyCode, Number shift)
Occurs when the user releases a key while a control has focus.

Scroll(Number keyCode, Number shift)
Occurs when the user scrolls the contents of a control.

**Command Control**
Command button control.

**Properties**

**ControlAppearance Appearance**
Sets or returns control appearance option. Read/write.

**Number BackColor**
Sets or returns background color. Read/write.

**String Caption**
Sets or returns control caption. Read/write.

**Picture DisabledPicture**
Sets or returns a graphic to be displayed when control is disabled. Read/write.

**Picture DownPicture**
Sets or returns a graphic to be displayed when control is pushed. Read/write.

**Boolean Enabled**
Sets or returns enabled option. Read/write.

**Font Font**
Sets or returns control font. Read/write.

**Boolean FontBold**
Sets or returns bold option of control font. Read/write.

**Boolean FontItalic**
Sets or returns italic option of control font. Read/write.

**String FontName**
Sets or returns facename of control font. Read/write.

**Number FontSize**
Sets or returns size of control font in points. Read/write.

**Boolean FontStrikethru**
Sets or returns strikethrough option of control font. Read/write.

**Boolean FontUnderline**
Sets or returns underline option of control font. Read/write.

**Number ForeColor**
Sets or returns foreground color. Read/write.

**Number MaskColor**
Sets or returns transparent color used in pictures. Read/write.

**Picture MouseIcon**
Sets or returns custom mouse icon. Read/write.
ControlMousePointer MousePointer
Sets or returns type of mouse pointer displayed over a control. Read/write.

ControlOleDrop OLEDropMode
Sets or returns OLE drop mode option. Read/write.

Picture Picture
Sets or returns a graphic to be displayed when control is up. Read/write.

Boolean RightToLeft
Sets or returns text display direction on a bidirectional system. Read/write.

ControlStyle Style
Sets or returns control style. Read/write.

Boolean UseMaskColor
Sets or returns transparent color option. Read/write.

Boolean Value
Sets or returns control value. Read/write.

Methods

DoClick()
Triggers the click event.

OLEDrag()
Starts an OLE drag/drop event with given control as the source.

Refresh()
Forces a complete repaint of control.

Events

Click()
Occurs when the user clicks a control.

KeyDown(Number keyCode, Number shift)
Occurs when the user presses a key while a control has focus.

KeyPress(Number keyAscii)
Occurs when the user presses and releases an ANSI key.

KeyUp(Number keyCode, Number shift)
Occurs when the user releases a key while a control has focus.

MouseDown(Number button, Number shift, Number x, Number y)
Occurs when the user presses the mouse button over a control.

MouseMove(Number button, Number shift, Number x, Number y)
Occurs when the user moves the mouse.

MouseUp(Number button, Number shift, Number x, Number y)
Occurs when the user releases the mouse button.
See Also

Scripting Reference
Component Control
Component control. Shows drawings, images, labels, maps, surfaces, and other components.

Properties

Point Center
Sets or returns center of view. Read/write.

Component Component
Sets or returns displayed component. Read/write.

String ComponentName
Sets or returns name of displayed component. Read/write.

Rect DataBounds
Sets or returns view bounds. Read/write.

Document Document
Sets or returns displayed document. Read/write.

String DocumentPath
Sets or returns path to displayed document. Read/write.

ControlMouseMode MouseMode
Sets or returns mouse mode. Read/write.

Boolean RenderBackground
Sets or returns background rendering mode. Read/write.

Boolean RenderBorder
Sets or returns border rendering mode. Read/write.

Boolean RenderControlPoints
Sets or returns control points rendering mode. Read/write.

Boolean RenderGraticule
Sets or returns graticule rendering mode. Read/write.

Boolean RenderGrid
Sets or returns grid rendering mode. Read/write.

Boolean RenderLegend
Sets or returns legend rendering mode. Read/write.

Boolean RenderNorthArrow
Sets or returns north arrow rendering mode. Read/write.

Boolean RenderScaleBar
Sets or returns scale bar rendering mode. Read/write.

Boolean RenderSelection
Sets or returns selection rendering mode. Read/write.
Number Scale
Sets or returns view scale. Read/write.

Number ScaleAbsolute
Sets or returns absolute view scale (e.g., 1:1000) for projected components. Read/write.

Boolean StatusBar
Shows or hides status bar. Read/write.

Boolean ToolBar
Shows or hides toolbar. Read/write.

**Methods**

Label GetLabelAt(Point point)
Retrieves label at given screen coordinates.

Object GetObjectAt(Point point)
Retrieves object at given screen coordinates.

GoTo(Branch branch)
GoTo(BranchSet branchSet)
GoTo(Component component)
GoTo(Geom geom)
GoTo(Label label)
GoTo(LabelSet labelSet)
GoTo(Object object)
GoTo(ObjectSet objectSet)
GoTo(Pixel pixel)
GoTo(PixelSet pixelSet)
GoTo(Point point)
GoTo(Rect rect)
Centers view on given branch, branch set, component, geom, label, label set, object, object set, pixel, pixel set, point, or rect.

Boolean HasLabelAt(Point point)
Check if there is a label at given screen coordinates.

Boolean HasObjectAt(Point point)
Check if there is an object at given screen coordinates.

Point NativeToScreen(Point point)
Converts point from the coordinate system of the displayed component to screen coordinates.

Refresh()
Repaints the control.

Point ScreenToNative(Point point)
Converts point from screen coordinates to the coordinate system of the displayed component.

ZoomIn(Number factor, Point center)
Zooms in with a given factor and center. Both parameters are optional.
ZoomOut(Number factor, Point center)
Zooms out with a given factor and center. Both parameters are optional.

ZoomTo(Branch branch)
ZoomTo(BranchSet branchSet)
ZoomTo(Component component)
ZoomTo(Geom geom)
ZoomTo(Label label)
ZoomTo(LabelSet labelSet)
ZoomTo(Object object)
ZoomTo(ObjectSet objectSet)
ZoomTo(PixelSet pixelSet)
ZoomTo(Rect rect)
Zooms to given branch, branch set, component, geom, label, label set, object, object set, pixel set, or rect.

ZoomToFit()
Zooms to fit entire component.

Events

BeginTrack(ControlMouseEventArgs args)
Occurs when the user starts tracking shape.

Click(ControlMouseEventArgs args)
Occurs when the user clicks a control.

DoubleClick(ControlMouseEventArgs args)
Occurs when the user double clicks a control.

EndTrack(ControlTracksEventArgs args)
Occurs when the user stops tracking shape.

MouseDown(ControlMouseEventArgs args)
Occurs when the user presses the mouse button within a control.

MouseMove(ControlMouseEventArgs args)
Occurs when the user moves the mouse within a control.

MouseUp(ControlMouseEventArgs args)
Occurs when the user releases the mouse button within a control.

MouseWheel(ControlMouseEventArgs args)
Occurs when the user scrolls the mouse wheel within a control.

See Also

Scripting Reference
**ControlMouseEventArgs Object**
Arguments of a mouse event raised by component control.

**Properties**

**ControlMouseButton Button**
Returns pressed or released mouse button. Read only.

**Boolean Canceled**
Accepts or cancels event. Read/write.

**Point LocationLatLon**
Returns event location in lat/lon coordinates. Read only.

**Point LocationNative**
Returns event location in component coordinates. Read only.

**Point LocationScreen**
Returns event location in screen coordinates. Read only.

**String Report**
Returns event report.

**Number WheelDelta**
The distance the wheel is rotated. A positive value indicates that the wheel was rotated forward, away from the user; a negative value indicates that the wheel was rotated backward, toward the user. Read only.

**See Also**

**ComponentControl** (BeginTrack, Click, DoubleClick, MouseDown, MouseMove, MouseUp)

Scripting Reference
ControlTrackEventArgs Object
Arguments of a mouse event raised by component control.

Properties

Geom GeomLatLon
Returns tracked shape in lat/lon coordinates. Read only.

Geom GeomNative
Returns tracked shape in component coordinates. Read only.

Geom GeomScreen
Returns tracked shape in screen coordinates. Read only.

Frame Control
Frame control.

Properties

ControlAppearance Appearance
Sets or returns control appearance option. Read/write.

Number BackColor
Sets or returns background color. Read/write.

ControlBorderStyle BorderStyle
Sets or returns control border style. Read/write.

String Caption
Sets or returns control caption. Read/write.

Boolean ClipControls
Sets or returns clipping option. When clipping is set to True, the frame clips contained controls when painting. Read/write.

Boolean Enabled
Sets or returns enabled option. Read/write.

Font Font
Sets or returns control font. Read/write.

Boolean FontBold
Sets or returns bold option of control font. Read/write.

Boolean FontItalic
Sets or returns italic option of control font. Read/write.

String FontName
Sets or returns facename of control font. Read/write.

Number FontSize
Sets or returns size of control font in points. Read/write.

Boolean FontStrikethru
Sets or returns strikethrough option of control font. Read/write.

Boolean FontUnderline
Sets or returns underline option of control font. Read/write.

Number ForeColor
Sets or returns foreground color. Read/write.

Picture MouseIcon
Sets or returns custom mouse icon. Read/write.

ControlMousePointer MousePointer
Sets or returns type of mouse pointer displayed over a control. Read/write.
ControlOleDrop OLEDropMode
Sets or returns OLE drop mode option. Read/write.

Boolean RightToLeft
Sets or returns text display direction on a bidirectional system. Read/write.

Methods

OLEDrag()
Starts an OLE drag/drop event with given control as the source.

Refresh()
Forces a complete repaint of control.

Events

Click()
Occurs when the user clicks a control.

DbClick()
Occurs when the user doubleclicks a control.

MouseDown(Number button, Number shift, Number x, Number y)
Occurs when the user presses the mouse button over a control.

MouseMove(Number button, Number shift, Number x, Number y)
Occurs when the user moves the mouse.

MouseUp(Number button, Number shift, Number x, Number y)
Occurs when the user releases the mouse button.

Scripting Reference
HScroll Control
Horizontal scrollbar control.

Properties

Boolean Enabled
Sets or returns enabled option. Read/write.

Number LargeChange
Sets or returns the amount of change to value when the user clicks the scroll bar area. Read/write.

Number Max
Sets or returns maximum value. Read/write.

Number Min
Sets or returns minimum value. Read/write.

Picture MouseIcon
Sets or returns custom mouse icon. Read/write.

ControlMousePointer MousePointer
Sets or returns type of mouse pointer displayed over an control. Read/write.

Boolean RightToLeft
Sets or returns text display direction on a bidirectional system. Read/write.

Number SmallChange
Sets or returns the amount of change to value when the user clicks the scroll bar arrow. Read/write.

Number Value
Sets or returns current value. Read/write.

Methods

Refresh()
Forces a complete repaint of control.

Events

Change()
Occurs when the contents of a control has changed.

KeyDown(Number keyCode, Number shift)
Occurs when the user presses a key while a control has focus.

KeyPress(Number keyAscii)
Occurs when the user presses and releases an ANSI key.

KeyUp(Number keyCode, Number shift)
Occurs when the user releases a key while a control has focus.

Scroll()
Occurs when the user scrolls a control.

**List Control**
List box control.

**Properties**

*ControlAppearance Appearance*
Sets or returns control appearance option. Read/write.

*Number BackColor*
Sets or returns background color. Read/write.

*Number Columns*
Sets or returns columns option. Value of 0 means that the control is scrolled vertically, values greater than 0 mean that the control is scrolled horizontally in snaking columns. Read/write.

*Boolean Enabled*
Sets or returns enabled option. Read/write.

*Font Font*
Sets or returns control font. Read/write.

*Boolean FontBold*
Sets or returns bold option of control font. Read/write.

*Boolean FontItalic*
Sets or returns italic option of control font. Read/write.

*String FontName*
Sets or returns facename of control font. Read/write.

*Number FontSize*
Sets or returns size of control font in points. Read/write.

*Boolean FontStrikethru*
Sets or returns strikethrough option of control font. Read/write.

*Boolean FontUnderline*
Sets or returns underline option of control font. Read/write.

*Number ForeColor*
Sets or returns foreground color. Read/write.

*Boolean IntegralHeight*
Sets or returns integral height option. Values of false indicated that control displays partial items. Read/write.

*Number ItemData(Number index)*
Sets or returns a number associated with given control item. Read/write.

*String List(Number index)*
Sets or returns text of given control item. Read/write.

*Number ListCount*
Sets or returns number of items in control. Read/write.
Number ListIndex
Sets or returns index of currently selected control item. Read/write.

Picture MouseIcon
Sets or returns custom mouse icon. Read/write.

ControlMousePointer MousePointer
Sets or returns type of mouse pointer displayed over an control. Read/write.

ControlMultiSelect MultiSelect
Sets or returns selection option. Read/write.

Number NewIndex
Sets or returns index of most recently added control item. Read/write.

ControlOleDrag OLEDragMode
Sets or returns OLE drag mode option. Read/write.

ControlOleDrop OLEDropMode
Sets or returns OLE drop mode option. Read/write.

Boolean RightToLeft
Sets or returns text display direction on a bidirectional system. Read/write.

Boolean Selected(Number item)
Sets or returns selection state of item with given index. Read/write.

Number SelCount
Sets or returns number of selected items in control. Read/write.

Boolean Sorted
Sets or returns sorted control option. Read/write.

ControlStyleList Style
Sets or returns control style. Read/write.

String Text
Sets or returns the text contained in control. Read/write.

Number TopIndex
Sets or returns index of topmost control item. Read/write.

Methods

Number AddItem(String item)
Appends new control item and returns its index.

Clear()
Removes all control items.

OLEDrag()
Starts an OLE drag/drop event with given control as the source.
Refresh()
Forces a complete repaint of control.

RemoveItem(Number index)
Removes item with given index.

Events

Click()
Occurs when the user clicks a control.

DbClick()
Occurs when the user doubleclicks a control.

ItemCheck()
Occurs when the user checks or unchecks control item (check list box controls only).

KeyDown(Number keyCode, Number shift)
Occurs when the user presses a key while a control has focus.

KeyPress(Number keyAscii)
Occurs when the user presses and releases an ANSI key.

KeyUp(Number keyCode, Number shift)
Occurs when the user releases a key while a control has focus.

MouseDown(Number button, Number shift, Number x, Number y)
Occurs when the user presses the mouse button over a control.

MouseMove(Number button, Number shift, Number x, Number y)
Occurs when the user moves the mouse.

MouseUp(Number button, Number shift, Number x, Number y)
Occurs when the user releases the mouse button.

Scroll(Number keyCode, Number shift)
Occurs when the user scrolls the contents of a control.

Option button control.

**Properties**

ControlAlignment Alignment
Sets or returns control alignment option. Read/write.

ControlAppearance Appearance
Sets or returns control appearance option. Read/write.

Number BackColor
Sets or returns background color. Read/write.

String Caption
Sets or returns control caption. Read/write.

Picture DisabledPicture
Sets or returns a graphic to be displayed when control is disabled. Read/write.

Picture DownPicture
Sets or returns a graphic to be displayed when control is pushed. Read/write.

Boolean Enabled
Sets or returns enabled option. Read/write.

Font Font
Sets or returns control font. Read/write.

Boolean FontBold
Sets or returns bold option of control font. Read/write.

Boolean FontItalic
Sets or returns italic option of control font. Read/write.

String FontName
Sets or returns facename of control font. Read/write.

Number FontSize
Sets or returns size of control font in points. Read/write.

Boolean FontStrikethru
Sets or returns strikethrough option of control font. Read/write.

Boolean FontUnderline
Sets or returns underline option of control font. Read/write.

Number ForeColor
Sets or returns foreground color. Read/write.

String Group
Sets or returns control group. Read/write.
Number MaskColor
Sets or returns transparent color used in pictures. Read/write.

Picture MouseIcon
Sets or returns custom mouse icon. Read/write.

ControlMousePointer MousePointer
Sets or returns type of mouse pointer displayed over a control. Read/write.

ControlOleDrop OLEDropMode
Sets or returns OLE drop mode option. Read/write.

Picture Picture
Sets or returns a graphic to be displayed when control is up. Read/write.

Boolean RightToLeft
Sets or returns text display direction on a bidirectional system. Read/write.

ControlStyle Style
Sets or returns control style. Read/write.

Boolean UseMaskColor
Sets or returns transparent color option. Read/write.

Boolean Value
Sets or returns control value. Read/write.

Methods

OLEDrag()
Starts an OLE drag/drop event with given control as the source.

Refresh()
Forces a complete repaint of control.

Events

Click()
Occurs when the user clicks a control.

DblClick()
Occurs when the user doubleclicks a control.

KeyDown(Number keyCode, Number shift)
Occurs when the user presses a key while a control has focus.

KeyPress(Number keyAscii)
Occurs when the user presses and releases an ANSI key.

KeyUp(Number keyCode, Number shift)
Occurs when the user releases a key while a control has focus.

MouseDown(Number button, Number shift, Number x, Number y)
Occurs when the user presses the mouse button over a control.

MouseMove(Number button, Number shift, Number x, Number y)
Occurs when the user moves the mouse.

MouseUp(Number button, Number shift, Number x, Number y)
Occurs when the user releases the mouse button.

- **Boolean FontUnderline**
  Sets or returns underline option of control font. Read/write.

- **Number ForeColor**
  Sets or returns foreground color. Read/write.

- **Boolean HideSelection**
  Sets or returns selection hiding option. When set to True, the control hides selection when it does not have focus. Read/write.

- **Boolean Locked**
  Sets or returns control locking option. Locked controls can not be edited. Read/write.

- **Number MaxLength**
  Sets or returns maximum number of characters that can be entered in a control. Read/write.
Picture MouseIcon
Sets or returns custom mouse icon. Read/write.

ControlMousePointer MousePointer
Sets or returns type of mouse pointer displayed over an control. Read/write.

Boolean MultiLine
Sets or returns control multiline option. Read/write.

ControlOleDrag OLEDragMode
Sets or returns OLE drag mode option. Read/write.

ControlOleDrop OLEDropMode
Sets or returns OLE drop mode option. Read/write.

String PasswordChar
Sets or returns password character. Read/write.

Boolean RightToLeft
Sets or returns text display direction on a bidirectional system. Read/write.

ControlScrollBars ScrollBars
Sets or returns control scroll bar options. Read/write.

Number SelLength
Sets or returns number of characters in text selection. Read/write.

Number SelStart
Sets or returns starting point of text selection. Read/write.

String SelText
Sets or returns text selection. Read/write.

String Text
Sets or returns the text contained in control. Read/write.

Methods

OLEDrag()
Starts an OLE drag/drop event with given control as the source.

Refresh()
Forces a complete repaint of control.

Events

Change()
Occurs when the contents of a control has changed.

Click()
Occurs when the user clicks a control.
DblClick()  
Occurs when the user double-clicks a control.

KeyDown(Number keyCode, Number shift)  
Occurs when the user presses a key while a control has focus.

KeyPress(Number keyAscii)  
Occurs when the user presses and releases an ANSI key.

KeyUp(Number keyCode, Number shift)  
Occurs when the user releases a key while a control has focus.

MouseDown(Number button, Number shift, Number x, Number y)  
Occurs when the user presses the mouse button over a control.

MouseMove(Number button, Number shift, Number x, Number y)  
Occurs when the user moves the mouse.

MouseUp(Number button, Number shift, Number x, Number y)  
Occurs when the user releases the mouse button.

Menus, Dialogs and Controls Reference

The topics in this section provide a reference to main menu choices, dialogs, toolbars, panes and context menus that occur with Manifold System. Read these topics together with overview topics found in the Introduction and general topics for each component type, such as Drawings, Images and so on.

To read all of the topics in the Menus, Dialogs and Controls chapters in Help, use the browse buttons to read them in sequence. Alternatively, press the Help Topics button in the Help system toolbar and in the Contents tab expand the Menus, Dialogs and Controls Reference headings to find the topic you would like to read.

File Menu

File - New / Open / Close

These File commands refer to Manifold projects. Individual components such as drawings, images and maps are imported or exported or created via the File - Export, File - Import and File - Link commands or the Create button in the project pane.

- **New** Create a new project.
- **Open** Open an existing project.
- **Close** Close the current project. Manifold will ask if we want to save the project if it has not been saved since the last change made.

Top open an existing project, browse the Windows file system to locate the Manifold project you wish to open. Click on a file to load it into the File name box and push Open, or simply double-click on the desired file.

- **Open as read-only** Check this box to open the specified project file "read only." This will allow viewing but will prevent any changes to the file.
**File - Save / Save As**

Save the current project under the given name. Browse the Windows file system to locate the folder in which you wish to save the project. Enter the desired name without a `.map` extension in the **File name** box and press **Enter** or push the **Save** button. The project will be saved to that name.

The project will now be known by that name. Any future Save commands will save the project to this file.

By default, Manifold will compress `.map` files to save space on disk. When working with large files the time required to decompress the `.map` file could be significant. For faster loads and saves, open the Tools - Options - **Miscellaneous** dialog and uncheck the **Compress .map files to save space** checkbox.
**File - Create**

The **File - Create** menu allows us to create new components in the project, for example, new blank drawings or images. It is frequently used to create new maps.

Some components that may be created must be created based upon some other component. For example, a new map must always be based on at least one existing drawing or image. The new map takes its initial projection properties from the component used to create it. These may later be changed if desired.

**Very Important:** To facilitate the creation of new components with projections that are a good match to components already in use, the **File - Create** commands will use the projection of the active window as the default projection for newly created components:

- If the project pane is the active window when **File - Create** commands are invoked, then the new drawings, images and text components will be created with a default projection of Orthographic centered at the 0,0 origin of the world latitude and longitude system.
- If some other window (such as a map window) is active, the **File - Create** commands will use that window's projection properties for the new component.
File - Export

Save the current component (the one opened in the active window) under the given name. A copy of the data for the component will be saved in the desired format. This command is most often used to export drawings, images and tables.

Browse the Windows file system to locate the folder in which you wish to save the component. Choose the desired file type from the list available in the Files of type box. Enter the desired name in the File name box without an extension and press Enter or push the Save button. The component will be saved to that name using the correct extension for that file type.

Files of type A pull-down box with a list of file types to which Manifold can export for this type of component. Choose the file type you wish to create.

The Files of type box will be loaded by default with the last type of file format that was exported.

When using the File - Export - Drawing dialog the Files of type choice acts as a filter for what is displayed in the browse pane in the Export dialog. Simple file types are exported directly from the Export dialog by choosing the desired type in the Files of type box. More complex exports into data sources such as databases are exported by choosing Data Sources () in the Files of type box and then using the Data Source dialog.

Drawings, images and surfaces can be exported into databases using spatial DBMS technology by using the Data Source dialog. See the Export Drawing - Oracle topic for a typical example of exporting to a spatial DBMS as can also be done for DB 2 with Spatial Extender, PostgreSQL/PostGIS, SQL Server 2008, SQL Server 2005 with Manifold Spatial Extender, and just about any DBMS using Manifold's ability to create and use generic spatial indices.

Using Enterprise Edition, any component can be exported into an Enterprise Server for shared storage.

Notes on Saving Components

Once components (like drawings and images) are imported into Manifold they become part of the project .map file. Saving the project saves the components within the .map file. At times we would like to import images, drawings or tables into Manifold and to later save them as independent drawing, image or table files.

To do this, we open the component in a window and then use the File - Export command to export it to the desired format. For example, we may import drawings in .shp format, manipulate them within Manifold, and then use File - Export to save them in .shp format for use with other software.

Note that not all formats can handle the full range of information possible in Manifold components. For example, tables in Manifold can contain field names that are fine for export to Access .mdb files but which are longer than allowed in the .dbf format used in dBase files. Such field names should be changed before attempting export to .dbf format.

Since .shp "shapefiles" are actually an ensemble of files that include the use of .dbf files for data attributes, this means that exporting a drawing (and, of course, its associated table) to .shp format means that field names in tables may need to be shortened. See the Export Drawing - SHP, Shapefiles topic.

By default, Manifold includes many more formats available for import than for export. Although all Manifold editions read .e00 format, only Enterprise Edition and higher can write .e00. Exporting to spatial DBMS usually requires Enterprise Edition.

Very Important

Before using Export with an image linked from an image server, see the Very Important discussion in the Image - Unlink command.

Exporting Layouts

The Data Source Dialog
Enterprise Edition
Spatial DBMS
**File - Import**

Find, open and import a component file into the project. Most components imported are drawings, images, tables or terrains.

Choose the desired file type from the list available in the **Files of type** box. Only those file types that may be used for the component being imported will be displayed. Browse the Windows file system to locate the file you wish to open. Click on a file to load it into the File name box and push **Open**, or simply double-click on the desired file. Importing a component brings a copy of the component's data into the project and will increase the size of the project file.

**Files of type**  
A pull-down box with a list of importable file types. Choose the file type you are searching for. Only those file types will be visible in the file-browsing window.

The **Files of type** box will be loaded by default with the last type of drawing file that was imported.

When using the **File - Export - Drawing** dialog the **Files of type** choice acts as a filter for what is displayed in the browse pane in the **Export** dialog. Simple file types are imported directly from the **Export** dialog by choosing the desired type in the **Files of type** box. More complex exports into data sources such as databases may be imported by choosing **Data Sources ()** in the **Files of type** box and then using the Data Source dialog.

Drawings, images and surfaces can be imported from databases using spatial DBMS technology by using the Database Console.

See the example topics referenced by the Manifold Spatial DBMS Facilities topic for typical examples of exporting and importing using a spatial DBMS as can be done with Oracle, DB 2 with Spatial Extender, PostgreSQL/PostGIS, SQL Server 2008, SQL Server 2005 with Manifold Spatial Extender, and just about any DBMS using Manifold's ability to create and use generic spatial indices.

Using Enterprise Edition, any component can be imported from an **Enterprise Server** providing shared storage.

Import and Export …and subsequent topics in the **Import and Export** chapter in Help.

**Exporting Layouts**

**The Data Source Dialog**

**Enterprise Edition**  
**Spatial DBMS**
File - Import - Component

Find, open and import a component file into the project from an existing Manifold .map project file. In the Import dialog navigate to a folder containing .map files and choose one of them in the File name box. Press Open. The map file will be decompressed and examined to see what components it contains and a list of these will be displayed in the Import MAP File dialog.

Check the components to be imported and press OK.

Import MAP File Dialog Commands

- Select All - Check all components for import.
- Select None - Uncheck all components.
- Select Inverse - Uncheck all checked components and check all unchecked components. A fast way to use all but one component: click Select None, check the one component not desired and then click Select Inverse.

See Also

File - Import - Component from Server
File - Import - Component from Server

Available in Manifold System Enterprise Edition only. If you have not licensed Enterprise Edition this command will not be available.

Find, open and import a component file into the project from an existing Manifold Enterprise server. Specify an Enterprise server in the **Server** box by entering the name of the data source or by entering the connection string, or browse to an ODBC data source by pressing the browse button next to the **Server** box. The box will remember the last-used Enterprise server connection.

Check the components to be imported and press **OK**. Checking or unchecking a component will check or uncheck all subsidiary components (such as labels components created using drawings and their tables). Hold down the **CTRL** key when checking or unchecking to check/uncheck a component without affecting the subsidiary components.

**Import from Server Dialog Commands**

- **Refresh** - Update the components pane with the latest contents of the Enterprise server. Use if the dialog has been open for a while and another user may have made changes from a different system.

- **Select All** - Check all components for import.

- **Select None** - Uncheck all components.

- **Select Inverse** - Uncheck all checked components and check all unchecked components. A fast way to use all but one component: click **Select None**, check the one component not desired and then click **Select Inverse**.
File - Link

Use the File - Link - Table dialog to link tables, drawings, images or surfaces into a Manifold project dialog. In addition, tables, drawings or images stored within databases using spatial DBMS technology can be linked by connecting to the database using Database Console, clicking on the table to highlight it and then clicking the Link button in the Database Console toolbar.

When using the File - Link - Table dialog the Files of type choice acts as a filter for what is displayed in the browse pane in the Link dialog. Simple file types are linked directly from the Link dialog by choosing the desired type in the Files of type box. More complex links from data sources such as databases are linked by choosing Data Sources () in the Files of type box and then using the Data Source dialog.

See the Importing and Linking Tables for information on linked tables.

Linked Drawings

A linked drawing is a special kind of drawing that is created on the fly from the information in a table or query. The table or query may be in the Manifold project or it may be a table or query in an external database provider. Linked drawings are shown in the project pane using an icon that include a yellow "database" cylinder to show they are created from a database table or query. Linked drawings can show points or lines.

All linked drawings can be formatted. In addition, in many cases a linked drawing can store formatting on the data source it has been linked from. This functionality has to be explicitly enabled by a database administrator using Database Administrator Edition. Linked drawings can be used to create subsidiary components, such as themes or labels.

There are two types of linked drawings in Manifold. One type of linked drawings is created directly from geocoded tables. An even more powerful form of linked drawings is the use of linked drawings created from tables that store geometry data. Linked drawings may be read-only or read/write depending upon their source.

Linked drawings that are linked from geometry in tables are normally read/write and may be fully edited just like a drawing in the local projection, including concurrent, multi-user editing of the linked drawing.

Linked drawings that are linked from geocoded tables are read-only and cannot be edited to move points or lines or to add or delete points or lines, except by editing the external table that controls them.

See these topics for information on linked drawings:

Linked Drawings
Geometry in Tables
Queries and Geoms

Linked Surfaces

Linked surfaces are like linked drawings in that they are created on the fly from the information in a table or query. The table or query may be in the Manifold project or it may be a table or query in an external database provider. Linked surfaces are shown in the project pane using an icon that include a yellow "database" cylinder to show they are created from a database table or query. Linked surfaces are normally read-only.

When a surface is linked from a table or query, each record in the table or query produces a pixel. The coordinates of the pixel are taken from the X and Y columns (cast to integer) specified in the Link dialog. The height of the pixel is taken from the Height column.

See these topics for information on linked surfaces:

Linked Surfaces
Virtual Tables for Images and Surfaces
Queries and Images or Surfaces
Geometry in Tables
Queries and Geoms
Linked Images

Linked images may be linked from several different sources. They may be created on the fly from information in a table or query, which may be inside the Manifold project or taken from an external database provider. In addition, linked images may be created by linking to a compressed image or by connecting to an image server that serves compressed images. Linked images are normally read-only. Finally, an image may be linked from an Oracle spatial data source that supports GeoRaster storage.

When an image is linked from a table or query, each record in the table or query produces a pixel. The coordinates of the pixel are taken from the X and Y columns (cast to integer) specified in the Link dialog. The color of the pixel is taken from either the Color column or the channel columns.

See these topics for information on linked images:

Compressed Images
Linked Images
Virtual Tables for Images and Surfaces
Queries and Images or Surfaces
Geometry in Tables
Queries and Geoms
File - Page Setup

The File - Page Setup command allows us to set paper orientation (portrait or landscape), paper size, printer, printer properties and margins. Page setup options will be applied to any print job and will be automatically incorporated into Layouts that may be created.

The Page Setup dialog uses inches or millimeters depending on the setting of the Use English Measurement Units checkbox in the Tools - Options dialog.

Note

Some multipage layouts of large maps using white backgrounds may result in some pages with no printing on them because the page falls entirely within a “whitespace” area of the map. By default, all pages are printed, even blank pages. To save paper, we can uncheck Print blank pages in multipage printouts in Tools - Options - User Interface.
File - Print
The contents of any component window may be printed in a default way with File - Print. The component will be printed on a single sheet (or multiple sheets in the case of text components using a simple dialog to set up the page. For much greater control over the appearance of a print job, use a Layout for printing.

The File - Print command calls the standard Windows Print dialog:

- **General tab** Choose the printer to use, the page range to print, collation and the number of copies.

The Printing Preferences dialog invoked by pressing the Preferences button in the Print dialog includes the following additional tabs (in older Windows versions these tabs may appear in the Print dialog itself):

- **Layout tab** Choose paper orientation from Portrait or Landscape. Includes an Advanced button to access any advanced configuration options available for the selected printer.

- **Paper/Quality tab** Choose paper tray selection. Also includes an Advanced button to access any advanced configuration options available for the selected printer.

See Also

How to Print

Layouts
File - Exit
Close all windows, close the project and exit Manifold System. Manifold will ask if we want to save the project if it has changed since the last save.

Edit Menu
Edit - Assign Projection
The Edit - Assign Projection dialog shows the coordinate system (projection) settings Manifold uses to interpret the coordinate numbers currently within a drawing or used with the pixels in an image. Changes in this dialog change merely the interpretation of the numbers and not the actual coordinate numbers or arrangement of pixels.

This dialog is also used to assign a projection to be used by a map. In this case, it tells the map what projection to use to display its contents. If the component layers in the map use different native projections, the map will re-project the components on the fly to show them as they would appear in the projection assigned to the map.

Note: This dialog is normally called just once when importing drawings or images from insensate formats. It is not the dialog to use to “re-project” a drawing or to specify a projection desired for a map. To re-project a drawing, image, or other component, use the Edit - Change Projection dialog.

The only time this dialog is used with components other than maps is to either verify the projection is correct or to specify the correct parameters after importing a projected component from a legacy format that does not contain projection parameter information. The component is imported as though it was unprojected (no parameters involved) and then this dialog is used to manually set the correct coordinate system parameters. Do not make changes in this dialog unless you are sure that the component was imported from a legacy format and now needs to have the correct coordinate system / projection parameters entered manually.

Although this dialog is visually similar to the Edit - Change Projection dialog (because both deal with similar data), the two are critically different in function. The Edit - Assign Projection dialog tells the system how to interpret existing data without modifying the data. The Edit - Change Projection dialog changes the data to fit a required interpretation.

The Edit - Assign Projection dialog is used to make changes on a “one time” basis only when an import from a legacy format requires manual entry of the correct projection parameters. Changing parameters in the Edit - Assign Projection dialog changes only the interpretation of the existing data and not the coordinate data.

The Edit - Change Projection dialog, in contrast, changes both the actual coordinate numbers as well as their interpretation. It is used every time one desires to recast a drawing or image into a new projection.
The dialog includes these controls:

- **Load from File** - Load projection information from a file using ERDAS AUX, Golden Software GSR, ESRI PRJ, or XML files.

- **Save to File** - Save projection information to a file using XML, Golden Software GSR or ESRI PRJ files.

- **Recent settings** - Choose a projection setting to reuse from a list of recently-used projections employed in this Manifold session.

- **Load from Component** - Load projection settings from another component in this project.

- **(Projection)** - A tree diagram providing numerous projections within various types of projections.

- **(Datum)** - A list of standard datums that incorporate various Earth ellipsoids and standard offsets.

- **(Parameters)** - One or more optional parameter settings, if used by this particular projection. Double-click into the values boxes to change them. Press Enter after changing a value.

- **(units box)** - Choose the unit of measure. All "unprojected" maps are in Degrees, Arc Minutes or Arc Seconds. Most projected...
maps are in meters.

**Local offset**
Shifted version of the external coordinate system peculiar to this component. Specifies shift in X (longitude) and Y (latitude) direction in the given units. With images or surfaces, the Local offset stores the offset to the left-bottom corner of the left-bottom pixel of the image or surface.

**Local scale**
Scaled version of the external coordinate system peculiar to this component. Specifies scale factor to be applied to external coordinate system.

**Scale correction**
Controls scale of the external coordinate system. For example, 0.9996 for UTM.

**False easting / northing**
Shift of the external coordinate system. For example, 500,000 meters for UTM. Some projections (such as UTM) add values to the "true" X and Y coordinates so that all coordinates stored are positive numbers. This avoids the use of the minus sign in primitive formats. The value added to X is the Easting and that to the Y is the Northing.

**Adjust for units**
Automatically adjust easting/northing values when units of measure are changed. Not checked by default.

**Clip coordinates**
Not used in the Edit - Assign Projection dialog.

**Autosuggest local values**
Not used in the Edit - Assign Projection dialog.

**Preserve local values**
Normally, choosing a projection from the projections pane will reset the values of Local offset, Local scale and units to the preset values for that projection. Checking this box will preserve any existing values in these local fields even when a new projection is selected. It is checked by default in the Edit - Assign Projection dialog because this dialog is often used to manually specify projection information when importing from geographically unaware legacy formats. In that case, any custom specifications for local values should probably be preserved when changing the projection.

**Suggest**
Suggest values for projection parameters based on the view in the component window. Used with projections with user-specifiable parameters.

The most frequent use of this dialog is to manually provide projection information when importing from formats too geographically unaware to provide such information (such as .shp or .dxf). After importing projected drawings from such files, the user must provide the missing projection information using the Edit - Assign Projection dialog.

To import a projected drawing or image from a legacy format:

1. Import the drawing or image using File - Import. Use default settings.
2. Open the drawing or image.
3. Use the Edit - Assign Projection dialog to specify the projection information that should be used.

The Edit - Assign Projection dialog allows us to manually provide the correct projection information into the coordinates properties. Manifold will then be able to make sense of the data just imported.

Do not confuse the assignment of a chosen projection view in a map window (via Edit - Assign Projection) with the use of Edit - Assign Projection in a drawing window to specify projection information missing from legacy formats. If a projected drawing is imported from, say, .shp format and you fail to tell Manifold the correct projection to use, that drawing has not yet been correctly imported. Subsequent use of the drawing in maps may
cause bizarre effects or lengthy delays as the system attempts to compute a new projection for the map based on fundamentally inaccurate coordinates.

**Note:** Maps can work faster if the drawings and images they contain as layers use the same projection that is requested of the map. If we always use a particular projection within a map, it will be worth it to re-project the constituent drawings and images of that map into that particular projection as well. To permanently re-project a drawing or image, use the Edit - Change Projection dialog.

**Adjust for units Option**

When manually changing units of measure the false easting and northing values will not be changed correspondingly. Checking the **Adjust for units** box will force a recomputation of the easting and northing values into the corresponding values for the new units of measure. For example, to change from Feet to Meters as units of measure and to change easting / northing accordingly:

- Verify the **Adjust for units** option is off,
- Set the units box to **Foot**,
- Turn on the **Adjust for units** option,
- Set the units box to **Meter**.

**Projection Toolbar Buttons**

We may want to re-use the same projection information with different components. For example, suppose we have many shapefiles covering the same region of interest that contain projected information requiring the use of the **Edit - Assign Projection** dialog after import. Since all of the files will require the same projection information, after importing one file and manually specifying the projection settings in the **Edit - Assign Projection** dialog we can save the projection information using the **Save to File** toolbar button. With subsequent files we can then use the **Load from File** button to load the settings and thus avoid manual re-entry of repetitive information.

Another time saver is to load projection information from an existing component using the **Load from Component** button. For example, we may want to re-project all files into a certain standard projection used by a given component and would like to be sure that all settings are identical. In that case, we open each component to be re-projected, launch the **Edit - Change Projection** dialog and use **Load from Component** to load the desired settings from the component we wish to use as the standard.

**Inadvertent Usage**

With components other than maps, the **Assign Projection** dialog should be used only once: when the component is first used to verify the projection is correct or to assign the correct projection if it was not correct. Using this projection in other circumstances is almost certainly a mistake.

In particular, it does not make sense to first verify the projection using the **Assign Projection** dialog, then change the projection using the **Change Projection** dialog and then finally to use the **Assign Projection** dialog. Once the projection is verified to be correct and then the projection is changed, it simply does not make sense to, in effect, state that the result is now wrong by attempting to use **Assign Projection** once more.

If we do attempt to use **Assign Projection** after doing a **Change Projection**, then Manifold will raise a warning message. If we elect to proceed, Manifold will allow us to continue as there are rare circumstances when expert usage may indicate a very minor change to a projection using **Assign Projection** after a **Change Projection** has been done. If we are in the habit of doing such exotic and expert things we can turn off the warning message by un-checking the **Confirm re-assigning projection after projecting data** option in the Tools - Options dialog.

**Additional Reading**

Experts may jump directly to the Projections Quick Reference topic. See the **Edit - Change Projection** topic for a discussion of the **Local scale**, **Local offset**, **Scale correction** and **False easting/northing** options. These are expert level parameters intended for professional use.
If you are new to coordinate systems in GIS or would like a refresher on coordinate systems and projections, consult the Coordinates Tutorial, the Projections Tutorial, and the Coordinates in Projected Maps topics followed by a quick review of the Projections Quick Reference topic for a summary.

See an example of usage in the Manually Georegister an Image example topic, in the Import a Projected Shapefile topic and in the Download and Mosaic Terraserver Images topic.

**Differences between Edit - Assign Projection and Edit - Change Projection**

- **Edit - Assign Projection** changes only the view of the data in maps and the interpretation of the data in other windows. It does not change the actual coordinates in the data. With map windows, it changes the projection used in the view without actually changing the data in the components. Map windows have dynamic projections that can show their contents in whatever projection is desired regardless of the native projections of what is inside them. When used with a drawing, image, labels or surface window it changes the interpretation of the data. This is a rarely used function that is utilized only to manually adjust projection properties when importing from formats that do not correctly store projection information.

- **Edit - Change Projection** appears with individual component windows such as drawing, image, labels or surface windows. This command changes the actual data in the component into a new coordinate system. There is no ability in a drawing window to see the drawing in a projection other than its native projection. We use **Edit - Change Projection** to re-project a component.

**Notes**

When opened with a read-only component (such as a drawing or other component stored on an Enterprise server when using Enterprise Edition), projection dialogs will report projection information but will not allow changes.

The **Assign Projection** and **Change Projection** dialogs also appear in the project pane context menu (right click on a component and the pop-up context menu appears). These dialogs will not be enabled in project pane context menus for components that take their projections automatically from parent components, for example, labels components bound to drawings or profiles.

**See Also**

**Edit - Change Projection**
Edit - Change Projection

The Edit - Change Projection dialog permanently changes the projection used for a drawing or image. With drawings, it changes the coordinate numbers within the drawing to their equivalents in the new projection, and then updates Manifold's coordinate properties for that drawing. With images or surfaces, it will re-compute the image by interpolating to add or delete pixels as necessary to match the image shape to the required projection.

To use the Change Projection dialog we must have first verified the projection currently assigned to the component to be re-projected. We do that by launching the Edit - Assign Projection dialog, making sure the existing projection is correct and then pressing OK. If we attempt to Change Projection without first verifying the projection, Manifold will not allow us to change the projection.

The dialog opens with a display of the current projection in use. Changing values in this dialog and then pressing apply will cause Manifold to re-compute the coordinate numbers within the drawing into their equivalents in the new projection. It is a permanent way of casting the data that define the drawing or image into a new projection.

The dialog includes these controls:

- **Load from File** - Load projection information from a file using ERDAS AUX, Golden Software GSR, ESRI PRJ, or XML files.

- **Save to File** - Save projection information to a file using XML, Golden Software GSR or ESRI PRJ files.
Recent settings - Choose a projection setting to reuse from a list of recently-used projections employed in this Manifold session.

Load from Component - Load projection settings from another component in this project.

(Projection) A tree diagram providing numerous projections within various types of projections.

(Datum) A list of standard datums that incorporate various Earth ellipsoids and standard offsets.

(Parameters) One or more optional parameter settings, if used by this particular projection. Double-click into the values boxes to change them. Press Enter after changing a value.

(units box) Choose the unit of measure. All "unprojected" maps are in Degrees, Arc Minutes or Arc Seconds. Most projected maps are in meters.

Local offset Shifted version of the external coordinate system peculiar to this component. Specifies shift in X (longitude) and Y (latitude) direction in the given units. With images or surfaces, the Local offset stores the offset to the left-bottom corner of the left-bottom pixel of the image or surface.

Local scale Scaled version of the external coordinate system peculiar to this component. Specifies scale factor to be applied to external coordinate system.

Scale correction Controls scale of the external coordinate system. For example, 0.9996 for UTM.

False easting / northing Shift of the external coordinate system. For example, 500,000 meters for UTM. Some projections (such as UTM) add values to the "true" X and Y coordinates so that all coordinates stored are positive numbers. This avoids the use of the minus sign in primitive formats. The value added to X is the Easting and that to the Y is the Northing.

Adjust for units Automatically adjust easting/northing values when units of measure are changed. Not checked by default.

Clip coordinates Enabled for projections like Orthographic: clip those parts of objects that extend past the projection extent. Manifold will clip coordinates to an accuracy of 0.01 degrees.

Autosuggest local values Enabled for images and surfaces: Automatically adjusts the values of local scale and local offset parameters after we change the coordinate system or alter one of the parameters in the parameter list. Checking Preserve local values overrides this box and keeps local values as they are.

Preserve local values Normally, choosing a projection from the projections pane will reset the values of Local offset, Local scale and units to the preset values for that projection. Checking this box will preserve any existing values in these local fields even when a new projection is selected. It is not checked by default in the Edit - Change Projection dialog because usually when re-projecting a component we want to use the preset local values associated with a new projection.

Suggest Suggest values for projection parameters based on the view in the component window. Used with projections with user-specifiable parameters.
Maps can work faster if the drawings and images they contain as layers use the same projection that is requested of the map. If we always use a particular projection within a map, it will be worth it to re-project the constituent drawings and images of that map into that particular projection as well. To permanently re-project a drawing or image, use the Edit - Change Projection dialog. In order for maps to run faster when the constituent drawings or images are in the same projection, they must use that same projection in all parameters. It does not help if both the map and its constituent drawings use Lambert Conformal Conic projection but with different center latitudes and longitudes.

Projection Toolbar Buttons

We may want to re-use the same projection information with different components. For example, suppose we have many shapefiles covering the same region of interest that contain projected information requiring the use of the Edit - Assign Projection dialog after import. Since all of the files will require the same projection information, after importing one file and manually specifying the projection settings in the Edit - Assign Projection dialog we can save the projection information using the Save to File toolbar button. With subsequent files we can then use the Load from File button to load the settings and thus avoid manual re-entry of repetitive information.

The Load from File button also provides a convenience when importing components created by other software packages. Using Load from File - Load projection information from a file using XML, Golden Software GSR or ESRI PRJ files.

Another time saver is to load projection information from an existing component using the Load from Component button. For example, we may want to re-project all files into a certain standard projection used by a given component and would like to be sure that all settings are identical. In that case, we open each component to be re-projected, launch the Edit - Change Projection dialog and use Load from Component to load the desired settings from the component we wish to use as the standard.

Sizing Images and Surfaces

When choosing Edit - Change Projection to re-project an image or surface the image size will often change slightly in size. The actual size of the resulting image or surface in pixels will be determined by the Local Scale parameters, which set by implication the size of each pixel. Choosing inappropriate scale parameters can result in absurdly large images or surfaces. Attempting to create a very large image or surface in this way will cause Manifold to raise a confirmation dialog.

Local Scale controls the image or surface resolution. A value of 5 meters means that each pixel of the resulting image will occupy an area of 5 meters by 5 meters. The greater the Local Scale, the fewer pixels the image will have. Local Offset specifies the offset to the left-bottom corner of the left-bottom pixel of the image or surface. When re-projecting images we can set the Local Scale. The system will compute Local Offset automatically.

Adjust for units Option

When manually changing units of measure the false easting and northing values will not be changed correspondingly. Checking the Adjust for units box will force a recomputation of the easting and northing values into the corresponding values for the new units of measure. For example, to change from Feet to Meters as units of measure and to change easting / northing accordingly:

- Verify the Adjust for units option is off,
- Set the units box to Foot,
- Turn on the Adjust for units option,
- Set the units box to Meter.

Discussion

Although this dialog is virtually identical to the Edit - Assign Projection dialog, the two are different in function. The Edit - Assign Projection dialog tells the system how to interpret existing data without modifying the data. The Edit - Change Projection dialog changes the data to fit a required interpretation.

The Edit - Assign Projection dialog is used to make changes on a "one time" basis only when an import from a legacy format requires manual entry of the correct projection parameters. Changing parameters in the Edit - Assign Projection dialog changes only the interpretation of the existing data and not the coordinate data.
The **Edit - Change Projection** dialog, in contrast, changes both the actual coordinate numbers as well as their interpretation. It is used every time one desires to recast a drawing or image into a new projection.

### Local and External Coordinate Systems

The offset, scale, scale correction and easting/northing factors are intended for expert use. These parameters are scale and offset values for use with either the local coordinate system or the external, projection coordinate system.

In a nutshell, the external coordinate system is a coordinate system specified by the projection and projection parameters as described in the usual treatises on projection systems. The internal or local coordinate system is the coordinate system peculiar to the component, which may be a scaled and shifted version of the external coordinate system. Local systems occur when working with images imported from certain formats and possibly with drawings as well.

The **Local scale** and **Local offset** values expose the internal values used by a component to control the scale and shift of the internal coordinate system. These are given in the projection's units of measure displayed in the units box.

The **Scale correction** and **False easting/northing** parameters control the scale and shift of the external coordinate system. "False easting/northing" is used instead of "offset" for historical reasons. These factors are commonly met in projection systems like UTM. **Scale correction** values are given in dimensionless units (such as 0.9996 for UTM) and **False easting/northing** values are given in degrees or meters depending on type of the coordinate system (such as 500,000 meters for UTM).

**Example:** When importing a Manifold System Release 4.50 map that uses a **Unit2Degree** factor of 10,000 (the default), the **Local scale** will be 0.0001 for both **X** and **Y**. This means that one native unit within the imported drawing equals 0.0001 degree. Modern Manifold editions still use full 1:250-millionth of a meter precision, but they will import the unit numbers from a 4.50 map knowing that the units used in that drawing had a scale factor of 0.0001.

**Example:** Increasing the **Local scale** in **X** of an image or drawing used as a layer in a map will make it look wider. Increasing the **Scale correction** in **X** will make it look narrower.

**Example:** Increasing the **Local offset** in both **X** and **Y** of an image or drawing used as a layer in a map will move the component towards the upper-right. Increasing the **False easting/northing** in both **X** and **Y** of an image or drawing used as a layer in a map will move the component towards the bottom-left (hence, the word "false").

**Local scale** and **Local offset** are applied to internal coordinates in a mirror image, inverse way as compared to how **Scale correction** and **False easting/northing** are applied to external coordinates within a projection system. In general, one can achieve exactly the same scale or offset effect by applying inverse values to either the local or the external scale/offset pairs.

The choice of which to use depends on the context of the activity. **Local scale** and **Local offset** values are better suited for manual georegistration while **Scale correction** and **False easting / northing** values are better for the professional use of projections.

### Differences between Major Projection Dialogs

There are two main projection dialogs that we use most frequently in Manifold.

The **Change Projection** dialog is used to change the projection of a component from one projection into another. It can only work correctly if the component already has been accurately assigned a projection. The **Assign Projection** dialog is used to verify and assign projections. It is used mainly to assign projections to components imported from formats that do not correctly store projection information. It is also used to assign the projection to be used by a map component.

- **Edit - Change Projection** is used to re-project a component into a different projection. This command changes the actual coordinate data in the component into a new coordinate system and also updates the projection assigned to that new projection. It appears with individual component windows such as drawing, image, labels or surface windows. It does not appear with map windows. We can only use **Change Projection** to change the projection of a component after we have verified that the projection assigned to that component is indeed correct using the **Edit - Assign Projection** dialog.
The assigned.

Why are there Two Projection Dialogs?

The need to have two projection dialogs that are confusingly similar to beginners, the Assign Projection dialog and the Change Projection dialog, arises from the GIS industry's inability to invent a clean and simple solution to the general use of projections. That the industry has been unable to invent a clean and simple solution is at the same time a negative sign and it is also a very positive sign about the health of the industry.

It is a positive sign because the GIS industry has become very large and a modern GIS like Manifold can read data from a vast number of formats used to store images, drawings and other data. Many sources for such data don't have anything to do with the GIS industry and so don't have the technical awareness that, say, a particular image might be used some day in a GIS package. Such sources don't bother implanting projection information into that image and might not even know what a projection is or how to correctly store such information.

For example, one day we may be flying in an airplane over an interesting view, and we might take a snapshot of that view with an ordinary consumer digital camera. The makers of the camera don't know anything about GIS and they have no way of knowing that a camera normally used to take snapshots of pets and birthday parties might also be used one day to take an aerial photograph that someone would like to use in a GIS package like Manifold. It is a testament to the power of GIS and to the power of Manifold that even though this image was acquired using non-GIS technology Manifold nonetheless has facilities (such as georegistration or the use of the Assign Projection dialog) that let us use that image in Manifold. Very cool.

The negative scenario driving the need for two dialogs is the very wide distribution within the GIS community of lots of data stored in absolutely terrible, poorly-designed formats that do not store projection information accurately. In years past many GIS packages were simply awful from a software design perspective and lacked the foresight to design a well-functioning format. In some cases, the old formats are limited because the equipment used to acquire the data was designed decades ago: for example, space technology changes so slowly that many of the sensors operating on today's satellites for space imagery were designed many years ago. They might have even been designed by people who never heard of DVDs, cell phones, Windows or the Internet.

There is an incredible amount of legacy junk out there in GIS, and some of it is still earnestly advocated by people who don't realize it is dreadfully obsolete. If you use a modern GIS like Manifold, to make an analogy with the music world, it is as if you are used to the modern world of MP3's and CDs but when you go down to your local
government GIS department you encounter a data librarian who thinks the world still uses eight-track audio tape cartridges and offers you one of those. While you stare at the antique thing thinking "you've got to be kidding..." the librarian is beaming with pride over what he or she thinks is modern technology.

To be absolutely fair, the widespread distribution of GIS data in junk, archaic formats is in some ways a positive sign: it shows that GIS has been around long enough for governments and organizations to acquire a really titanic amount of data about our world already stored in some sort of GIS format. That's very useful because getting that into Manifold is usually easy if you pay attention to some small details. It's also positive in that we wouldn't think of such archaic formats as being utter junk if the GIS industry were not evolving so rapidly that new things like Manifold appear to make the old stuff seem so old-fashioned. But it still complicates matters for beginners.

How Projections Work

To understand why we need two confusingly similar projection dialogs we need to understand how projections are made to work. Bear with us and do not skip over this section as it is critically important to understanding how to operate Manifold or any other GIS.

When we pop open a drawing the system draws pretty lines and areas and points based upon data sitting in a file somewhere. That data consists of a series of paired numbers that give the locations of coordinates needed to draw what we see in a "connect the dots" fashion. If you zoom far enough into any drawing you'll see that even though the drawing may appear to have smooth curves, when viewed close up it always consists of straight line segments that are drawn between coordinate locations.

To make this system work, where a file with a bunch of numbers in it is displayed as a pretty drawing, there are two things that the GIS system has to know how to do:

- It has to have some coherent scheme for representing coordinate locations as numbers, and
- It has to know how to display those numbers as objects in the drawing.

Obviously, whoever designs the GIS package better make sure that whatever scheme is chosen for coordinate numbers is something that is understood by the module used for display.

Software designers can come up with all sorts of ways of storing coordinates as numbers in files and indeed there are many ways of doing so. A simple package could store numbers that specify latitudes and longitudes of coordinates. A CAD package like AutoCAD could store numbers that represent some arbitrary X,Y grid position in a blueprint. A technical cartographic package might store numbers like 43080934098.3048939 that represented some grid location within a projected coordinate system.

It almost doesn't matter what numbering system is used to encode the coordinates so long as the rest of the GIS package knows how to use those numbers to display objects in the drawing and to work with them. The key thing is that the part of the software that works with those stored coordinate numbers must understand what they are supposed to mean. It is as if the drawing were stored in one language, English, and the display software had to understand that English was used as well.

To continue this analogy, it doesn't matter if the drawing were stored in Japanese if the display software also understood it was Japanese. That would OK as well. But, a situation where the drawing was stored in Japanese and the display software thought it were English would be a problem, or if it were stored in English and the display software thought it was in Japanese would also be a problem. The key thing is that both parts of the system must agree on what is supposed to be going on.

A more technical reader at this point may jump ahead to think, "Hey, all that is great, but if here I sit using Manifold, why do I care what other systems might do? Why is it simply not the case that Manifold picks some way of storing numbers, understands within itself what it is doing, and we can then forget about any of these complications?" Good question.

Manifold can and does indeed have an internal format for storing coordinates that all the other parts of Manifold understand perfectly. In a perfect world we'd never have to worry about any of this stuff. There are two catches to why we still need two projection dialogs and why Manifold's internal system does not simplify life as we would like:

- We have to get data from other systems into Manifold, and other systems have all sorts of different ways of storing numbers for drawings. Sometimes that's easy to deal with, but sometimes we have to figure out how the other system stores coordinate numbers and what it intended. For this reason...
(and for others) we need a dialog that we can use to tell Manifold what is intended. That's why we have an Assign Projection dialog.

- Because of the limits of hardware speed, even within Manifold itself just one way of storing coordinate numbers is not fast enough to allow us to use many different projections. Sometimes we have to use different coordinate number schemes to get the performance we want. For this reason, we need a dialog that we can use to tell Manifold to change the numbers into a different scheme. That's why we have a Change Projection dialog.

The first point above will get beaten to death in endless essays and topics throughout this documentation. Reading those topics will help the Manifold user get street-smart about exploiting data acquired in dumb formats. We won't go further into it here.

The second point is more interesting and often comes as a surprise to non-technical users. In modern times we all are used to computers storing things internally in various magic ways without needing to know how all that technical wizardry is accomplished, so it may come as a surprise to have to think about how that is done. But that happens in GIS because GIS data sets are often so huge that even with modern desktop computers we have to make some manual compromises to be able to work with such data.

It's a bit like having an automatic transmission in a car as opposed to a manual transmission: if you have a really weak engine in a car but still have to carry heavy loads you might need to learn how to use a clutch and how to manually shift gears to eke out every last bit of capability. In the GIS world, sometimes to deal with the limits of processing on desktop computers we have to know how to manually "shift gears" by re-projecting a drawing or other component.

If all computers were super-fast supercomputers, we could always store all coordinate numbers using the same scheme, for example, as simple latitude and longitude numbers, and then whenever we needed to show them in some projection we could tell Manifold what projection to use and Manifold would make the calculations on the fly to show the data in the desired projection. No matter how big the drawing might be, no matter how many numbers may be involved, if a fast enough supercomputer were doing the work Manifold could instantly show the drawing to us in whatever projection we wanted. That would be like an automatic transmission in a car.

In fact, computers have gotten fast enough that Manifold can often do just this when we show drawings or other components in a map window if the drawings or images are not too large. If the drawings use a different projection (that is, their data is stored using a different number scheme) than the projection used by the map, the map will actually re-compute the display on the fly so that the drawing layers appear in that map as if they used the map's projection as their own native projection.

The problem is that only goes so far. When the drawing gets big enough, the time required to re-compute the drawing's numbers into a different projection takes so long that users get annoyed while their maps take forever to display. Most GIS images are already so big that users don't want them re-projected on the fly. If we are cursed with the bad luck of not having a supercomputer on our desktop we will want the display process to go faster and to do that we will have to change projections manually sometimes, like using a stick shift in a car.

The way to make the display process go faster is to change the numbers inside the drawing into a numbering scheme that directly implements the desired projection. On a one-time basis we can re-compute the coordinate numbers inside the drawing so that it later can be displayed in the desired projection without any need to re-compute it on the fly. It's true we have to wait while the drawing is re-projected, but that only happens once and then every time we display it in that projection it displays fast. This is what the Change Projection dialog does. It changes the innards of a drawing or other component so that the native projection is the one we desire, the one in which we expect to work with the drawing.

All the above notions set up a two stage methodology involving projections. We have to know what the numbers are used inside any given drawing, image or other component. The numbering scheme used internally is the native projection used inside the drawing. And then also Manifold has to be told what projection is supposed to be used with those numbers, which is the assigned projection. Obviously, the assigned projection should match the native projection.

All Manifold features and functions will automatically make sure that happens, assuming that the data set was correctly set up (that is, the assigned projection matched the native projection) in the first place. If we use the Change Projection dialog to change the native projection of a drawing, Manifold will not only change the native projection but it will also change the assigned projection to match as well. We can therefore use Change Projection to re-compute the numbers (that is, to re-project the numbers) inside a drawing into whatever projection we want for fastest possible work. Inside Manifold, it all works automatically and perfectly with nothing to worry about.
But when we bring something into Manifold from outside, we may need to tell Manifold what those numbers are supposed to mean. In that case, we will use the **Assign Projection** dialog to tell Manifold what projection to assign to that drawing so that the assigned projection matches the numbering scheme used inside the drawing.

You might think that when Manifold imports a drawing or image it should know what the numbers are supposed to mean. If we are importing from a modern GIS format that correctly stores projection information that will happen and we won’t have to worry about using **Assign Projection**. But if we are stuck importing from some stupid format like DXF or ESRI shapefiles, then we will have to use **Assign Projection**. That’s life in the big city.

You might think that anyone with common sense, no matter how much a beginner at programming, would make sure that any format they designed for storing GIS data would also embed some information as to what the numbers are supposed to mean, but unfortunately the programmers who designed many of the world’s GIS legacy formats lacked the foresight to do so. So, we are stuck with hacks like shapefiles filling up the world’s hard disks and stuck with the need to manually use **Assign Projection** to import such things. At least we can be grateful that Manifold has tools to let us import such data almost no matter what format it is in.

**Two More Uses for Assign Projection**

OK, so we use **Change Projection** to re-compute the numbers inside a component and we can trust Manifold to also assign the right projection to match that re-computation when it is done. If we bring something into Manifold from some wacko format and need to tell Manifold what those numbers mean, we use the **Assign Projection** dialog. So far, so good.

In addition to the above, we also use the **Assign Projection** dialog in two related uses that are so similar in purpose that we can use this same dialog for them:

- **To verify** the projection that has been assigned to a component. Manifold won’t trust that a drawing or other component has been imported correctly with the right projection assigned, even if we import the item from some smart format. Instead, Manifold insists that we take a quick look at the projection that was assigned by popping open the **Assign Projection** dialog and pressing **OK**. This verification step is required to protect beginners from themselves, because if the correct projection is not assigned on import then chaos will ensue. Experts can turn this verification requirement off in the **Tools - Options** dialog.

- **To assign** the projection that a map is supposed to use. Although a GIS expert may quibble that this is a slightly different intent than what is discussed above, the concept is so similar (changing the way the data is interpreted rather than re-computing the data itself) that the **Assign Projection** dialog is used in this case as well. It’s the same information and dialog boxes required so we may as well use the same dialog.

**Notes**

When opened with a read-only component (such as a drawing or other component stored on an Enterprise server when using Enterprise Edition), projection dialogs will report projection information but will not allow changes.

The **Assign Projection** and **Change Projection** dialogs also appear in the project pane context menu (right click on a component and the pop-up context menu appears). These dialogs will not be enabled in project pane context menus for components that take their projections automatically from parent components, for example, labels components bound to drawings or profiles.

**Additional Reading**

Experts may jump directly to the Projections Quick Reference topic.

If you are new to coordinate systems in GIS or would like a refresher on coordinate systems and projections, consult the Coordinates Tutorial, the Projections Tutorial, and the Coordinates in Projected Maps topics followed by a quick review of the Projections Quick Reference topic for a summary.

See also the Projections and Images topic.

**See Also**

**Edit - Assign Projection**
Edit - Change Projection
Edit - Undo / Redo
A limited form of Undo and Redo that provides single-step undo and redo capabilities in certain contexts when ambiguities can be resolved. Comments, queries and scripts allow multi-level Undo and Redo. Certain operations (for example, certain remote database operations) cannot be undone.

It is always wise, therefore, to make frequent saves and to always work with copies of important data in case changes get out of hand.

When working with large images and surfaces the Undo command requires the creation of large temporary files. The process of creating such temporary files can be quite slow and result in annoyingly slow performance when working with very large images and surfaces. Many users prefer to turn off Undo in such cases.

The parameters specified in Tools - Options - Confirmation allow users to the size of images and surfaces that preserve the ability to Undo. The Confirm creating undo actions larger than… option provides two controls:

- The ability to ask for confirmation before an Undo action is undertaken when image or surface size exceeds a given number of megabytes, by default, 50 megabytes.
- A standing specification to never undertake an Undo action larger than a given number of megabytes, by default, 250 megabytes. If this second parameter is reduced to a very small number of megabytes the effect will be to turn off Undo except for very small images and surfaces.

Note: Script windows, query windows and comments are unusual in that they support multi-level Undo / Redo. One can CTRL-Z (Undo) backwards through many changes and CTRL-Y (Redo) forwards to redo many Undo operations.

Tech Tip
Many transform operators for drawings automatically run a Normalize Topology transform before running to eliminate common errors that may affect correct operation. When such an operator is undone, the normalization that automatically preceded it will also be undone.
Edit - Cut / Copy

Either **Cuts** and copies or simply **Copies** selected items onto the Windows clipboard. Shortcuts are CTRL-X for Cut and CTRL-C for Copy.
Edit - Paste / Paste Append
Pastes contents of the Windows Clipboard into the active component. Edit - Paste Append appears in components such as drawings, tables or comments, where data may be appended onto existing text or records.

When copying objects from one drawing and pasting into another the Paste Objects dialog appears to allow control of how fields are pasted.

Paste Objects Dialog Controls

Select All - Paste all columns.
Select None - Do not paste any columns except ID.
Select Inverse - Do not paste all current Paste As columns and paste all other columns. A fast way to use all but one column: click Select None, specify a Paste As choice for the one column not desired and then click Select Inverse.
Autoselect - Paste existing fields to compatible columns where the names are the same and otherwise create a new field as necessary.

Column This column lists fields in the source drawing.
Paste As How the field should be pasted into the destination drawing. Double-click into a Paste As cell to

Pasting Drawings, Images or Surfaces as Tables
The Paste As dialog that appears when pasting drawings, images or surfaces as tables the columns offered will be intrinsic fields relevant to that component.

See Also

Intrinsic Fields in Tables
Project Pane - Paste as Surface
Project Pane - Paste as Drawing
Edit - Delete / Delete All
Appears with all components where items may be selected or highlighted.

Delete   Delete all items in the selection.
Delete All Delete all objects or pixels in the component. Will always ask for confirmation before deleting everything.
Menus, Dialogs and Controls Reference

**Edit - Select All / None / Inverse**
Changes selection throughout entire component at once.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select All</td>
<td>Select all objects or pixels in the component.</td>
</tr>
<tr>
<td>Select None</td>
<td>Deselect all objects or pixels in the component.</td>
</tr>
<tr>
<td>Select Inverse</td>
<td>Invert the selection. Those items that were not selected will become selected, while those that were selected will be deselected.</td>
</tr>
</tbody>
</table>

Select All and Select None are obvious in action, as seen above using an image as an example.

Select Inverse is a very useful command, because sometimes when making a selection it is easier to pick out those things we do not want to select. For example, if we ultimately would like to select the land area of South America in the images above, it is easier to first use Touch Select to select ocean areas and to then use Edit - Select Inverse to get the land areas. The ocean regions are very even in color and can be selected with a single click. The land areas contain many different colors and would take many clicks when using a reasonable tolerance setting with Touch Select.

These commands also work with drawing layers. In the sequence above, we would like to retain a circular region of lines in a drawing layer while deleting all other lines. We do this by selecting the circular region, choosing Select Inverse and then deleting the new selection (all the lines except the ones we want).
These commands also work with charts, tables and even forms.

For example, if one control in a form is selected, using **Select Inverse** will select the other controls.
Edit - Select Mode

The Edit - Select Mode menu provides menu access to selection mode buttons on the Selection toolbar. Selection mode buttons control how a new selection made with a selection tool is combined with any existing selection. One selection mode button is always pushed in.

- **Select Replace** - Replace the existing selection with whatever is now selected.
- **Select Add** - Add whatever is now selected to the existing selection.
- **Select Subtract** - Subtract whatever is now selected from the existing selection.
- **Select Invert** - Deselect whatever is now selected that was already in the existing selection and otherwise add what has just been selected.
- **Select Intersect** - Select only the region of overlap between what is specified by the tool and what is in the existing selection. If there is no overlap, nothing will be selected.

See the main Selection topic for details and examples.
Edit - Select Objects

The **Edit - Select Objects** menu appears with drawings to provide menu access to selection mode buttons on the
Selection toolbar.

Selection filter buttons allow us to specify what types of objects are selectable. This is very useful when working
with complex maps with lots of objects in sight, because it allows us to enable selections only for certain items,
such as points.

Choose the type of items that are to be selected by pushing the selection filter buttons for the desired types. The
buttons above show selection enabled for points and disabled for areas, lines and pixels. If we drew a selection
rectangle over a region in the map that contained all four types of items, only the points within the rectangle will
be selected. Areas, lines and pixels within the rectangle will be ignored.

![Select Areas](image1)

Select **Areas** - Enable selection of areas by mouse
selection tools.

![Select Lines](image2)

Select **Lines** - Enable selection of lines by mouse
selection tools.

![Select Points](image3)

Select **Points** - Enable selection of points by mouse
selection tools.

![Select Pixels](image4)

Select **Pixels** - Enable selection of pixels by mouse
selection tools.

![Select Text](image5)

Select **Text** - Enable selection of text labels by mouse
selection tools.

All four filter buttons may be used in maps. When working with drawings, the **Select Pixels** button will be
disabled. When working with images, **Select Area**, **Select Lines** and **Select Points** buttons will be
disabled. When working with images, **Select Pixels** is always enabled and will be shown in a "forced" style that
cannot be clicked out.

This menu appears only for drawings, because with images **Select Pixels** is always the only filter button enabled.

See the main Selection topic for more information on selections.
Edit - Select by Type

The Edit menu includes a Select by Type choice. Use this command to select all of one or more types of objects, that is, all areas, lines or points in the drawing. The Select by Type command applies whatever Selection Objects and Selection Modes settings are in force.

For example, to select all of the points in a drawing we would push in the Select Points button and the Replace Selection button and then choose Edit - Select by Type. All points in the drawing will be selected, replacing any previous selection.

If we simply wanted to add all the points to the current selection we would have pushed in the Add to Selection mode button and then chosen Edit - Select by Type.
Edit - Modify Selection

This menu item appears with images only. The Edit - Modify Selection menu provides four choices for modifying the shapes of regions of pixels that have been selected:

- **Border**: Take the current region of selection and convert it to region of selected pixels that are +/- the given width of pixels from the boundary of the current region.
- **Contract**: Shrink the region of selected pixels by the given number of pixels.
- **Expand**: Expand the region of selected pixels by the given number of pixels.
- **Smooth**: Create a smoother periphery of the selected region using the given parameters.

See the Modifying Selections topic for details and examples.
Masks are grayscale images that are used to control other images. Masks are used for two purposes:

- To make a selection in the shape shown by the mask.
- To alter the values in the R, G, B or alpha channels of the target image using the values in the mask.

A mask can be any grayscale image. There is nothing special about grayscale images used as masks. What makes a grayscale image a "mask" is simply how we use it. See the Selection using Masks and Masks topic for details and examples.

We can create masks using any method used to create or edit grayscale images. Since masks are often used as a means of saving selections or other patterns from existing images Manifold provides an Edit - Save Mask/Channel command that makes it easy to create a mask using an existing image.

These commands can also be used with surfaces.

**Choices for Save Mask/Channel**

Any of the following aspects of an image may be saved as a mask:

- The Selection.
- The region of invisible pixels.
- Any saved selection we have made for this image in the Selections pane.
- The R, G, or B channels in the image if it is an RGB image.
- The alpha channel in the image if it is an RGBA image.

**Note:** The Save Mask/Channel dialog will not list any saved selections that are empty. If no selection is present in the image the dialog will not include a Selection choice. If the dialog contains no invisible pixels there will be no choice for Invisible pixels available.

We can load an image using a mask as a guide by using the Edit - Load Mask/Channel command.

**Choices for Load Mask/Channel**

Using a mask we can load any of the following aspects of an image:

- The Selection.
- Make the pixels in a given region invisible pixels.
- The R, G, or B channels in the image if it is an RGB image.
- The alpha channel in the image if it is an RGBA image.

When used to specify the Selection or invisible pixels every pixel in the mask that is black signifies no selection or no invisible pixel at that spot. Any pixel that is not black signifies making a selection or an invisible pixel at that spot. When using a mask to specify a region of invisible pixels any previously invisible pixels will remain invisible since making a pixel invisible is always a "one-way" operation that deletes the pixel.

When used to specify an R, G, B or alpha channel the value from 0 to 255 of the grayscale pixel is used for the value of the specified channel for that pixel location.

**Load** Which part of the image is to be loaded. The selection, a channel, or invisible pixels.

**From** The source image to use for the mask. All grayscale images available will be listed together with their sizes.

**Mode** Specifies how to use the mask within the target image:
Add - Add the intensity values of the mask pixels to the target.

Invert - If the intensity of a mask pixel is greater than 128, invert the value of the target pixel.

Maximum - Use the maximum of intensity of either the mask pixel or the target pixel.

Minimum - Use the minimum of intensity of either the mask pixel or the target pixel.

Replace - The default. Use the values of the mask pixels.

Subtract - Subtract the intensity of the mask pixel from the target pixel.

Restrict to Selection - If checked (the default), when a selection is present the mask will be applied only within the selected pixels.

See the Masks topic for examples.

Use with Surfaces

The Edit - Save Mask/Channel dialog for surfaces includes choices to save a grayscale image, invisible pixels or aspect or slope data in single-precision floating-point format into new surfaces. Aspects vary from -180 to 180 degrees. Slopes are given in degrees. Surfaces created using this dialog will retain the coordinate system (projection) and saved selections of the original surface.
Edit - Find / Find Next

Appears with all components that contain text or have searchable data associated with them. Searches with regular expressions to match a custom pattern of characters are allowed if the Use regular expressions box is checked.

**Very important:** Searches proceed from the current record to the last record in the table. To begin at the beginning, we must press the Restart button.

Any located object found with Find or Find Next becomes the primary selected object and clears the selection.

<table>
<thead>
<tr>
<th><strong>Find what</strong></th>
<th>The value or regular expression to be found.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Match whole word only</strong></td>
<td>Match the value only when it occurs as a whole word. With this checked, &quot;the&quot; will match the word the but not occurrences of these letters within words such as weather.</td>
</tr>
<tr>
<td><strong>Match case</strong></td>
<td>Find is case insensitive by default. This forces a match exactly on the case given in the Find What value. Example: unchecked, &quot;the&quot; will match The and The.</td>
</tr>
<tr>
<td><strong>Use regular expressions</strong></td>
<td>Regular expressions are a concise and flexible notation for finding and replacing patterns of text.</td>
</tr>
<tr>
<td><strong>Search only in</strong></td>
<td>By default, Find will search all fields. Check this to restrict the search to only the field given.</td>
</tr>
<tr>
<td><strong>Find Next</strong></td>
<td>Find the next instance of the value.</td>
</tr>
<tr>
<td><strong>Find All</strong></td>
<td>Find and select all instances of the value.</td>
</tr>
<tr>
<td><strong>Restart</strong></td>
<td>Move the current record pointer to the beginning of the table. Searches proceed from the current record pointer only.</td>
</tr>
<tr>
<td><strong>Close</strong></td>
<td>Close the dialog</td>
</tr>
</tbody>
</table>

See the Regular expressions topic for information on using regular expressions. Regular expressions are a sophisticated and flexible way of searching for patterns of text.
Edit - Replace

Appears with all components that contain text or have searchable data associated with them. Searches with regular expressions to match a custom pattern of characters are allowed if the Use regular expressions box is checked.

Very important: Searches proceed from the current record to the last record in the table. To begin at the beginning, we must press the Restart button.

Any located object replaced with Replace or Replace All becomes the primary selected object and clears the selection.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>

<tr>
<td>Restart</td>
<td>Move the current record pointer to the beginning of the table. Searches proceed from the current record pointer only.</td>
</tr>
<tr>
<td>Close</td>
<td>Close the dialog</td>
</tr>
</tbody>
</table>

See the Regular expressions topic for information on using regular expressions. Regular expressions are a sophisticated and flexible way of searching for patterns of text. Regular expressions can also be used for specifying the Replace with text.
Edit - Advanced

The Edit - Advanced menu becomes available when editing text components such as comments, scripts and queries.

- **Make Lowercase**: Convert all characters in the selected text to lowercase.
- **Make Uppercase**: Convert all characters in the selected text to uppercase.
- **Comment Selection**: Comment out the selected lines of text.
- **Uncomment Selection**: Uncomment the selected lines of text.
- **Wrap Selection**: Appears for comments. Word wrap the selected text to the current window width.
- **Join and Wrap Selection**: Appears for comments. Word wrap the selected text to the current window width, deleting single line breaks to form single paragraphs.
- **Complete Word**: Appears for queries. Complete the word automatically if an unambiguous choice is possible. If no unambiguous choice is possible, pop up a list of choices (the same as Complete Word with List). Usually invoked with the standard Microsoft CTRL-space shortcut.
- **Complete Word with List**: Appears for queries. Pop up a list of possible completions. Not usually used, since checking (the default) the Automatically list completion suggestions when editing queries box in Tools - Options - Miscellaneous causes the list to pop up automatically.

Each command has a keyboard shortcut that is listed next to the command.

Comments

Manifold understands commenting conventions for a variety of languages, including SQL, VBScript, JScript, Python, PERL and .NET languages such as C#, VB .NET and JScript .NET. Comment style will be taken from the language used for a script or for SQL for a query.

Programmers will become familiar with the CTRL-K and CTRL-SHIFT-K sequences to comment and uncomment sections of code.

Join and Wrap Selection

This command joins paragraphs separated by a single line break but does not join paragraphs separated by two line breaks (that is, a blank line between paragraphs).

Consider a comments text window with three paragraphs, each separated from the others by two line breaks. We select the text and choose Edit - Advanced - Join and Wrap Selection.
The result is that each paragraph is wrapped to the current width of the window in use.

Consider the case where the same paragraphs are separated by only one line break at the end of each line. Once again we select the text and choose **Edit - Advanced - Join and Wrap Selection**.

Once again the text is wrapped, but this time the paragraphs are **joined** into a single paragraph.
Bookmarks are icons in the left margin of text components such as comments, queries and scripts. They allow fast navigation within lengthy text. Bookmarks are also available within tables and queries. Within tables they are very useful for marking particular records when jumping back and forth between records in a table. When tables or queries are sorted the bookmarks correctly travel with the records into the new sort order. If comments, queries or scripts are edited the affected bookmarks will be offset or removed as necessary.

The illustration above shows a bookmark icon in the left margin.

To set a bookmark:
1. Open the component.
2. Click on the line or record where the bookmark is to be placed. This positions the cursor on that line.
3. Press F8 or choose Edit - Bookmarks - Toggle from the main menu.

To clear a bookmark:
1. Go to the line or record marked with the bookmark to be cleared. (Use Edit - Go To or simply position the cursor on that line).
2. Press F8 or choose Edit - Bookmarks - Toggle from the main menu.

Note that the Toggle command sets a bookmark if one is not present and clears a bookmark if one is already present. The Edit - Bookmarks - Remove All command clears all bookmarks from the active component.

To go to a bookmark:
1. Choose the Edit - Go To command.
2. Choose Bookmark in the Go To box.
3. Choose the desired bookmark in the lower box and press OK.

The lower box provides a list of bookmarks shown using the line number and the first few characters of the line.
In the Go To dialog shown above we are about to jump to the bookmark at line 434 that is shown in the illustration at the beginning of this topic.

**Color Used**

Set the color used for bookmark icons in the Colors page in the Tools - Options dialog. Preferred bookmark color seems to be a very personal issue. The default is cyan to match Microsoft Visual Studio style. Some users prefer yellow or green.
**Edit - Breakpoints**

Breakpoints are icons in the left margin of script components that mark a program line at which execution automatically stops when the Manifold Debugger is in use.

Breakpoints are used together with the debugger to debug scripts. Breakpoints may be set at a given line to stop execution at that line. Once set, a breakpoint may be disabled to allow execution to flow past that line while still marking the line so it is easy to locate. Breakpoints appear in the left margin of scripts. If scripts are edited the affected breakpoints will be offset or removed as necessary.

The illustration above shows two breakpoint icons in the left margin. The lower round icon in the margin of the script shows a disabled breakpoint. Execution will flow past that line, although we can still use the breakpoint Go To Next / Previous commands or the Edit - Go To command to jump to that breakpoint and line quickly. The upper red icon in the margin is an enabled breakpoint. Execution will stop at that line.

- **Toggle** - Cycle the breakpoint at this line between "no breakpoint", "breakpoint set" and "disabled breakpoint."
- **Go to Previous** - Go to the previous breakpoint (includes both disabled and enabled breakpoints).
- **Go to Next** - Go to the next breakpoint (includes both disabled and enabled breakpoints).
- **Delete All** - Clear all breakpoints from this component.

<table>
<thead>
<tr>
<th>F9</th>
<th>Toggle</th>
</tr>
</thead>
<tbody>
<tr>
<td>SHIFT-CTRL-F9</td>
<td>Go to Previous</td>
</tr>
<tr>
<td>CTRL-F9</td>
<td>Go to Next</td>
</tr>
</tbody>
</table>

**To set a breakpoint:**

1. Open the component.
2. Click on the line where the breakpoint is to be placed. This positions the cursor on that line.
3. Press F9 or choose Edit - Breakpoints - Toggle from the main menu.

**To cycle a breakpoint:**

1. Go to the line marked with the breakpoint to be disabled or cleared. (Use Edit - Go To or simply position the cursor on that line).
2. Press F9 or choose Edit - Breakpoints - Toggle from the main menu to disable the breakpoint.
3. Again press F9 or choose Edit - Breakpoints - Toggle from the main menu to clear the breakpoint.

Note that the **Toggle** command cycles breakpoint status for a given line between no breakpoint, breakpoint set and a disabled breakpoint. The **Edit - Breakpoints - Remove All** command clears all breakpoints from the active component.
To go to a breakpoint:

1. Choose the Edit - Go To command.
2. Choose Breakpoint in the Go To box.
3. Choose the desired breakpoint in the lower box and press OK.

The lower box provides a list of breakpoints shown using the line number and the first few characters of the line.

In the Go To dialog shown above we are about to jump to the disabled breakpoint at line 7 that is shown in the illustration at the beginning of this topic.

Colors Used

Set the colors used for breakpoint line background in the Colors page in the Tools - Options dialog. If the Highlight Entire Lines option is on, the breakpoint color will be used for the background color of the line containing the breakpoint. The default appearance is similar to that used in Microsoft's Visual Studio.

See Also

Debugger
**Edit - Go / Go To**

*Edit - Go To* provides a rapid way of panning and zooming to a desired view. Options include:

- **Address** Enabled if the Geocoding Tools extension has been installed. Go to a given street address when that address is provided either in full or partial form.

- **Layout** Enabled if a layout has been created. Pan and zoom to that layout.

- **Location (latitude / longitude)** Go to a given latitude, longitude coordinate.

- **Location (projected coordinates)** Go to a given coordinate using projected coordinates. Handy for use with UTM and similar systems.

- **Objects** Go to all objects (zoom to entire component), the selection or to a saved selection.

- **Zip code** Enabled if the Geocoding Tools extension has been installed. Go to a given ZIP code.

*Edit - Go* appears with tables only, and allows jumping the current record to the First, Next, Previous, Last or end position in the table to insert a new Blank record.

With script, comment and query windows, *Edit - Go To* can jump to any text line or bookmark if bookmarks have been inserted into the component. Go To in scripts can jump to any breakpoint if breakpoints have been inserted into the component.

To jump to a particular bookmark, choose it in the lower combo box and press OK. Bookmarks will be shown prefaced with their line numbers.

To jump to a breakpoint, choose Breakpoint in the Go To combo box and then choose the breakpoint desired. To jump to a line number, choose Line in the Go To box and then enter a line number in the lower box.
Geocoding Tools

If the Manifold Geocoding Tools extension has been installed the Edit - Go To command will allow a GoTo to an Address or to a Zip code. Area of coverage depends upon the geocoding data source that is being used. For example, using the Manifold geocoding database coverage will extend to the US only. If MapPoint is used coverage will be the North American or European coverage provided by the MapPoint edition in use.

The address may be a full street address, or it may be a partial address, such as "Atlanta" or "Atlanta, GA" or "GA." Manifold includes a gazetteer of large city names so that "Atlanta" will find the large city in Georgia and not one of the various small towns of that name throughout the US. City names will take priority over states when spelled out, so that "Washington" will find the capital city of the US and not the state. To find the state, use "WA."

Geocoding Data Sources
**Edit - Snap To**

Checking a choice in the **Edit - Snap To** menu controls Snap modes, which work with mouse cursor motion. Snap modes force the mouse cursor to take effect only at those discrete, specified locations that are nearest to the mouse cursor's location. We can also set snap modes using Snap Toolbar buttons. When snap modes are engaged the status bar will show snap is turned on.

When any snap mode is engaged a secondary reticule cursor will show the point of action. For example, with **Snap To - Points** set the point that is nearest to the mouse cursor will be highlighted with a reticule cursor that is magenta in color. If we click with the left mouse button the mouse cursor will jump immediately onto that point. This makes it possible to exactly pick out the location of a given point, for example to edit its position.

Checking **Edit - Snap To - Lines** will cause the snap cursor to jump to the nearest coordinate defining a line. In the illustration above, as the regular cursor is brought near the end of a line the snap cursor will appear at the end of the line.

As the cursor is brought near the end of the other line, the snap cursor will jump to the end of that line.

**Snap Modes in Drawings:**

- **Graticule**
  - Snap to graticule intersections if View - Graticule is enabled.

- **Grid**
  - Snap to grid intersections, if View - Grid is enabled. Frequently used when adding controls to Forms.

- **Areas**
  - Snap to the coordinates that define areas.

- **Lines**
  - Snap to the coordinates that define lines.

- **Points**
  - Snap to points.

- **Segments**
  - Snap to arbitrary locations on segments defining line or area objects.

- **Selection**
  - Snap only to those objects in the selection. Requires snap to areas, lines or points to be enabled.

More than one snap mode can be set simultaneously. For example, if **Snap to Areas**, **Snap to Points** and **Snap to Selection** are all checked then the cursor will jump to the nearest point or area coordinate that is in the selection.

**Grid and Graticule Snap Modes**

Snapping to grids and graticules is supported in most components; with drawing, image, labels, map, profile, surface and theme windows support snapping to grids and graticules.
Snap Modes in Layouts:

- **Grid**: Snap to grid intersections, if View - Grid is enabled.
- **Elements**: Snap to the corners of an element.

Changing Snap Action with TAB and Space Bar

- **TAB**: Depressing the TAB key jumps the cursor immediately onto the snap reticule. This is used when we want the mouse cursor to jump immediately to the snap point without a mouse click.
- **Space Bar**: Depressing the space bar turns off snap temporarily until the space bar is pressed again. This is very useful to temporarily turn snap off. When snap is turned off using the space bar the status bar will not show snap modes enabled.

Example

Suppose we would like to use the Tracker tool to measure distances from one point to other points. With Snap to Points checked, we position the snap reticule over the desired Tracker origin point and click with the left mouse button. Now, we move the mouse cursor near the point for which tracker measurement is desired so that the snap reticule highlights that point and we press the TAB key: the mouse cursor will immediately snap onto that point and the Tracker readout will provide the distance to that point. To measure the distance to another point we can move the reticule onto another point and press TAB again and the mouse cursor will snap to that point, and so on.

Snap modes also work in the middle of other commands. For example, suppose we would like to draw a circle that is centered on one point and that has its edge exactly on a particular area.
We push in **Snap to Points** and **Snap to Areas** and then use the **Insert Circle on Center** drawing tool to click on the first point and then drag the circle out to the area. In the example above, the magenta snap cursor appears at the point initially clicked. As we bring the mouse cursor near the area a square secondary snap cursor will appear at various coordinates that define the area that are nearest to the mouse cursor. When we release the mouse drag the circle will be created as denoted by the magenta snap cursor and the secondary box cursor.

**Example**

In this example we will reposition labels to the intersections of a grid.

Consider an unbound labels component. This was created as a bound labels component of place names in Mexico using the Mexico example drawing as a parent and then unlinked to create an unbound labels component. The example would work the same using a bound labels component, but if we had used a bound component the parent objects would have been shown in schematic preview in the background and thus the display might not have been as clear.

The component has been projected into Lambert Conformal Conic projection using default **Suggest** button values.

We first turn on grids by using **View - Grid** to specify a grid for the view to display. We use default values for the grid.
Next, we select one of the labels to be moved for editing by CTRL-ALT clicking on it.

When the label is selected for editing an edit handle appears at the tie point for the label.

At this point we can turn on Snap to Grid, but when we do so we discover we cannot click on the label's edit handle to drag it to a different position. When we try to do so we find that the Snap mode moves the cursor reticule onto the nearest grid intersection and not onto the edit handle as we would like.

The solution is to tap the spacebar on our keyboard to temporarily turn off Snap mode. We can then click and hold onto the edit handle so the square edit cursor appears on the edit handle. We hold the click down...
...while we simultaneously tap the **spacebar** again to turn **Snap** mode back on. The edit cursor now under the influence of **Snap** mode immediately jumps to the grid intersection nearest to the mouse arrow cursor.

When we release our click-and-hold the label snaps to the grid intersection.

We can click on the label again (which we can do without using the **spacebar** because it is now at a grid intersection to which the cursor will jump in **Snap** mode) and, holding the click, move the mouse arrow cursor to a different location.
As the mouse arrow cursor nears the upper grid intersection the square edit cursor jumps to that intersection.

When we release the click-and-hold the label will snap to the upper intersection.

**Snap Tolerance**

The **Snap Tolerance** parameter may be optionally specified in the Tool Properties pane to control how close the mouse must be to a snap item before a snap mode takes effect.

When a snap mode is on, the **Snap Tolerance** setting gives the distance in screen pixels or in physical units within which the cursor must be to a given snap item (such as a line when snapping to lines) before the cursor snaps to that item.

When the cursor is outside the snap tolerance range, snaps are not effective. Setting a small snap tolerance is therefore a good way of retaining the benefits of snap modes without having the snap cursor jump about in a disconcerting way if the mouse is nowhere near a snappable item.

**Layer Snap Restrictions**

Using Layer Restrictions a map layer can be made non-snappable. When a layer is so restricted, any snap modes will ignore items in that layer.

**Note**

Snap must find the nearest point for every mouse motion. The snap cursor will lag behind mouse motion if there is a very large number of points on screen, if we move the mouse very rapidly (snap will catch up when we slow down), or if the system is heavily loaded with a background task.

**Troubleshooting**

If snap appears not to be working, try pressing the spacebar to see if snap has temporarily been turned off. When snap is on the status bar will show snap mode turned on. If snap has been turned off using the space bar, the status bar will not show snap mode enabled even if a snap mode toolbar button is pressed in.

Tool Properties
Edit - Shared Edit

The Edit - Shared Edit setting controls the operation of mouse-based editing commands. When Shared Edit is on, any click and drag of the mouse will affect all objects that have a defining coordinate at the mouse click location. When Shared Edit is off, only that object that has been selected for editing will be affected.

Shared Edit may be turned on and off using CTRL-E as a keyboard shortcut ("E" being a mnemonic for "Edit"), or by clicking the Shared Edit choice in the Edit menu.

When Shared Edit is on, a box will appear around the Shared Edit icon in the Edit menu.

When Shared Edit is off, there will be no box around the Shared Edit icon in the Edit menu.

Example

The easiest way to show the effect of Shared Edit is to turn it on and try a simple example.

Consider a drawing that has four lines. Three of the lines have been drawn using the Snap to Lines snap mode so that their ends are exactly at the end of the fourth line. At the ends of the four lines five points have been placed, also using Snap to Lines snap mode, so that the points are exactly at the ends of the lines.

This is a fairly typical example of lines and points that might occur in a drawing of, say, a system of roads or a network, where the ends of lines are exactly coincident and where points might be placed exactly at the ends of lines. Suppose we would like to edit this drawing to move, say, the position of one of the points and we would like to simultaneously change the position of any incident lines.

That would be tedious to do without Shared Edit capability, but with Shared Edit mode turned on it is very easy to do.
Suppose we would like to move the central point and to move all incident lines with it. We being by CTRL-ALT clicking on the point to select it for editing. An edit handle appears.

We can now click on the point and drag it to a new location.

With Shared Edit mode turned on, when the point moves, the coincident coordinates of all incident objects move with it. The four lines with ends exactly under the point will have their ends also moved. What is happening is that the coordinates defining the end of each line are also changed when the point's coordinates are changed by moving the point.

This works regardless of which object has been selected, and it even works if the different objects are in different layers and we are editing them in a map.
Suppose, for example, we **CTRL-ALT** click on the uppermost line to select it for editing. Edit handles appear at the two coordinates that define the line.

We can now click and drag the edit handle on the bottom coordinate to move it.

With **Shared Edit** mode on, when we move the edit handle for the line we change the line, but the point at that location also moves and so do the ends of the other three lines.
Let's consider what would have happened if we did not have **Shared Edit** mode on. Suppose we **CTRL-ALT** click the upper line to select it for editing.

Once again, we could click and drag the bottom edit handle to move it.

However, if **Shared Edit** mode is turned off then moving the bottom edit handle will move only the coordinate for that one object and will not move the point and the ends of the other three lines that were coincident with it.

**Editing Areas with Shared Edit**

**Shared Edit** mode is very useful for editing areas where areas are adjacent. It's often the case with geographic maps that areas will be drawn adjacent to each other. If we want to edit the boundary of an area to move it slightly we will also need to correspondingly move the boundary of any adjacent areas to avoid creating gaps or overlaps.

Geographic regions such as provinces or states are often represented as areas in geographic maps. The "border" between two states in an error-free geographic map is a place where the boundaries of two different areas coincide. Let us digress for a moment to make this concept clear:
The illustration above shows a map that has two layers, each containing an area object. The areas have been drawn so they are exactly adjacent to each other along a common border. What appears to be a single line, a "border," is in fact simply the place where the coordinates of two different area objects happen to coincide.

We can see this by clicking the layers on/off for display that contain the two areas.

One layer contains an area colored in gray. This area is defined with seven coordinates, five of which define the right edge of the area.

The other layer contains an area colored with a blue pattern. This area is also defined with seven coordinates. The left edge of the blue patterned area is also defined with five coordinate locations.

What gives the appearance of a common “border” is that the five coordinates defining the right edge of the gray area are exactly coincident with the coordinates defining the left edge of the blue area.

This is the usual case in most geographic maps. Unless there is a boundary dispute between two states, normally where the territory of one state ends is where the other state begins, so there should not be any gaps or overlaps at the place where two areas meet.

To move the common boundary line, we want to move the coordinates of both the gray area and the blue area simultaneously. To do this, we turn Shared Edit mode on and we will use regular editing commands to change the shape of one area with the other area's shape being changed automatically.
For example, we can select the area on the right for editing by **CTRL-ALT** clicking it so edit handles appear at each of the area’s coordinates and then we can drag edit handles about to change the shape of the area.

To move the central part of the border we can click and drag the leftmost edit handle to the right.

With **Shared Edit** turned on, the result is that the corresponding coordinate for the gray area is also moved to the right. This changes the shape of the gray area as well so that no gaps or overlaps appear. Note that this works even though the two areas are in different layers in the map window in which we are working.

Had we done this same edit with **Shared Edit** turned off, only the coordinate for the area selected for editing would have been moved. The coordinate for the gray area would not have been moved and thus a gap would appear between the two areas.
**Edit - Instant Data**

*Instant Data* make repetitive data entry a snap in drawing windows or in drawing layers in map windows. This is a mode command. It is either checked or not checked in the *Edit* menu. When checked, all subsequent object creation commands, like *Insert Point*, will call up the *Instant Data* dialog.

When an object is created, the *Instant Data* dialog allows us to enter a value into a specified field. The field box will be loaded with all write-enabled fields available in the drawing's table. Choose a desired field and enter the value. Thereafter, when *Instant Data* opens it will show that field and value by default. The *Instant Data* dialog remembers the last field used and opens with the field name pre-loaded and the cursor positioned in the value box. Type in the value desired and hit *Enter* or click on *OK*.

![Object Fields Dialog](image)

**To use Instant Data**

1. Open a drawing window or click on a drawing layer in a map to make it active.
2. Click *Instant Data* in the *Edit* menu to check it ON.
3. Choose a tool to insert the objects you want, for example, *Insert Point*.
4. Click the location where you wish to insert a point. The *Instant Data* dialog will open.
5. In the *Column* box, choose the field for which you want to add data.
6. In the *Value* box, enter a value for that field.
7. Press *OK*.
8. Continue adding objects. Each time the *Instant Data* dialog will appear preloaded with the name of the field and the last value added. Change the values as desired. If for some objects you wish to add a value in a different field, choose the new field in the *Column* box.
9. When finished using *Instant Data*, click it off in the *Edit* menu.

Use *Instant Data* when you must create many objects and wish to add a value for each. For example, suppose we need to add many points to a map and we wish to enter a name for each in a field called *Name*. Check *Edit - Instant Data* and then we can use *Insert Point* to click where we want each point. Enter the name, hit *Enter* and click on the next point.

*Instant Data* thus allows a very rapid repetitive data-entry rhythm: click a point - enter a value, click a point - enter a value, and so on. Please note that because *Instant Data* is used to load values into a database field for newly-created objects the *Instant Data* dialog only appears when there are fields defined in the drawing's table. If we create a new, blank drawing the *Instant Data* dialog will not be available until we add some fields to the drawing's table.

*Instant Data* remembers the last value used for each drawing. If we turn on *Instant Data* and then add points to different drawing (say, by clicking into different drawing windows or by changing the active layer in a map), the *Instant Data* dialog will be loaded with the last field used and last value used for each drawing.
Using Instant Data when Several Objects are Created

Manifold commands can be used to create many objects at once. For example, if the Insert Areas tool is used with Create Areas, Create Lines, and Create Points modes on the area with a line object at the boundary and point objects at the coordinates that define the area.

When several objects at once are created, the instant data dialog tries to identify the "main" object for which a data field value is to be assigned, using the order of precedence: areas, lines and finally points. For example, when creating an area with a boundary line and points at the defining coordinates the area will be taken as the "main" object and the instant data dialog will set a data field value for the area.

If no object can be obviously identified as the "main" object the instant data dialog will not launch even if Edit - Instant Data is checked. For example, we can use the Insert Box tool with Insert Points mode set ON to create four points at the corners of a box. There is nothing to distinguish any of the four points as being more "main" than any of the other points, so the instant data dialog will not launch in this case.

Example

Suppose we have a map that shows various regions in a drawing. In another drawing we would like to show the location of sampling stations as points. Each station has a name.

1. Create a new drawing and drag it into the map.
2. Click open the table for the new drawing.
3. Add a text field called Name to the table.
4. Click on the map and click on the new drawing's tab to make it the active layer.
5. Check Edit - Instant Data
6. Choose Insert Point
7. Click at a location where a sampling station is to be located. A point will be created and the Instant Data dialog will appear.
8. Choose the Name field in the Field box and then enter the text for the name of this sampling station in the Value box. Press Enter or click OK.
9. Click at the location of the next sampling station. The Instant Data dialog will appear once more with the Name field already loaded and the most-recently entered text in the Value box (this facilitates entering the same value over and over). Enter the name for this next sampling station.
10. Repeat the cycle above until all the sampling station points have been created.

When finished using Instant Data, take a moment to uncheck Edit - Instant Data

See Also

See the Add Points with Instant Data example topic for an example of adding points, using Instant Data and moving points by editing intrinsic fields.
**Edit - Template**

The Template menu command appears in the Edit menu when a print layout is open and has the focus. This command allows application of layout templates or other layouts to the current layout, or saving the current layout to a file for use as a template.

- **Apply**
  - **Apply a template** - Apply a built-in template to this layout.
  - **Apply a layout** - Apply a different layout in the project as a template to this layout.

- **Apply File**
  - Apply a layout template stored in a file to this layout.

- **Save**
  - Save this layout to a file for future use as a layout template.

**See Also**

- Layouts
- Layout Templates
- Custom Layout Templates

**View Menu**

**View - Columns**

Show or hide columns in tables and specify their order. The View - Columns dialog shows all fields available in the table, with a readout at the bottom of the dialog that shows how many columns are currently shown out of the total number or columns in the table. The dialog also shows the data type of each column's field.

For tables linked to drawings, the View - Columns dialog will also list all intrinsic fields available. Intrinsic fields are system-generated fields that report information, such as latitude and longitude location, for each object.

Check the column box to show that column. Click on a column to highlight it and then the Move buttons to move it up or down in order.

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Contact Name</td>
<td>Text (Uni)</td>
</tr>
<tr>
<td>Contact Title</td>
<td>Text (Uni)</td>
</tr>
<tr>
<td>Address</td>
<td>Text (Uni)</td>
</tr>
</tbody>
</table>

- **Show All** - Show all columns in the table.
- **Hide All** - Hide all columns in the table.
- **Show Inverse** - Uncheck all checked columns and check all unchecked columns. A fast way to show all but one column: click Hide All, check the one column not desired and then click Show Inverse.
- **Move to Top** - Move highlighted column to the top of the list. This places the column at the leftmost position of the table.
- **Move Up** - Move highlighted column up one position in the list. This moves the column one step to the left in the table.
Move Down - Move highlighted column down one position in the list. This moves the column one step to the right in the table.

Move to Bottom - Move highlighted column to the bottom of the list. This places the column at the rightmost position of the table.

See the main Tables topic for details on tables.
View - Selection Filter
Enabled for tables. Push in to filter the table so that only selected records are shown

With the focus on a table window, push in the Selection Filter button either in the main toolbar or in the View - Filter dialog. The table will then show only selected records. Records will appear and disappear from a table window filtered Selection Filter as they are added to or subtracted from the Selection.

Example

Import the sample drawing of Mexico provinces from the Manifold CD. Open the drawing and open the drawing's table. Click on the table window so it has the focus and push in the Selection Filter button.

Initially, there is no selection in the drawing.

The table therefore shows no records since there is nothing in the selection and with the Selection Filter button in the table will show only selected records.
If we click on the province of Durango to select it…

...It will immediately appear in the table as well.

If we use Select Add mode and use Select Touch to click on two more provinces…
Components, Dialogs and Controls Reference

...Their records also will immediately appear in the table.

**Query Toolbar Restricted to the Selection Filter**

When the selection filter button is engaged subsequent operations of the query toolbar will apply only to those records that are shown in view by the selection filter. This makes it easy to run simple queries that refine the result of a previous query toolbar operation.

Suppose we select records with values in column A greater than 0. Suppose we now want to select records with values in column B greater than 0, regardless of what is in column A. That's easy to do as we simply run the query toolbar again.

Now suppose we again select records with values in column A greater than 0, but this time we also want to find within those selected records only those records that have values in B greater than 0 as well. After making the selection with the query toolbar to find those records with values in A greater than 0 we turn on the selection filter so that those records are shown and then next we run the query toolbar one more time to find those records that also have values in B greater than 0.

**See Also**

**Selection**
View - Sort

This dialog sorts tables using multilevel sorts on several fields at once. It shows all the columns in the table and allows specification of ascending or descending Order for each field. Specify the order of the column by double-clicking into the Order field and choosing either ascending or descending order.

Manifold reads the precedence to be used from the top down to the bottom of fields listed in the Sort dialog. Fields that do not have an ascending or descending sort order specified will be ignored.

- **Move to Top** - Move the highlighted filter rule to the top of the list.
- **Move Up** - Move the highlighted filter rule up one position in the list.
- **Move Down** - Move the highlighted filter rule down one position in the list.
- **Move to Bottom** - Move the highlighted filter rule to the bottom of the order of the list.
- **Use Case** - Specify case sensitive or case insensitive (the default) sort. A case sensitive sort will place records beginning with capital letters at the top of the table and those beginning with the same letter in lower case at the bottom of the table.
- **Use Side Whitespace** - Use or ignore leading and trailing spaces in sort order. Suppose a red dash "-" indicates a space character: If turned on, "A" sorts before "B"
- **Use Interior Whitespace** - Use or ignore interior spaces in sort order. Suppose a dash "-" indicates a space character: If turned on, "A-B" (with two spaces between "A" and "B") sorts before "A-C" (with one space between the letters).

**Order** Sort this field by ascending or descending order. Ascending order means records beginning with A will be at the top of the table and those beginning with Z will be at the bottom. Descending order will have records beginning with Z at the top of the table.

To Sort a Table using Multilevel Sort

1. In the View - Sort dialog, click on the field to be used as the topmost level sort.
2. Use Move Up to move it above any other field used for sorting.
3. Click into the Order cell for this field and specify ascending or descending sort.
4. Repeat the above process for fields to be used for sub-sorting.

Example

We have a database we wish to sort first by State and then by City fields.

<table>
<thead>
<tr>
<th>State</th>
<th>Order</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

 ascendant, descendent
Double-click into the **Order** cell for the **State** column and choose *ascending*.

<table>
<thead>
<tr>
<th>Column</th>
<th>Order</th>
</tr>
</thead>
<tbody>
<tr>
<td>City</td>
<td></td>
</tr>
<tr>
<td>State</td>
<td>ascending</td>
</tr>
</tbody>
</table>

Double-click into the **Order** cell for the **City** column and choose *ascending*.

<table>
<thead>
<tr>
<th>Column</th>
<th>Order</th>
</tr>
</thead>
<tbody>
<tr>
<td>State</td>
<td>ascending</td>
</tr>
<tr>
<td>City</td>
<td>ascending</td>
</tr>
</tbody>
</table>

Click on the **State** column to highlight it and use **Move Up** to move it above the **City** field in the list if it is not already above it.

This will result in a table that has all the records sorted by state first and then within each state they will be sorted by city names. To find a particular record we can scroll down to the state and then look within the state for the particular city name.

<table>
<thead>
<tr>
<th>Column</th>
<th>Order</th>
</tr>
</thead>
<tbody>
<tr>
<td>City</td>
<td>ascending</td>
</tr>
<tr>
<td>State</td>
<td>ascending</td>
</tr>
</tbody>
</table>

If we were to use **Move Up** to move the **City** field above the **State** field the resultant sort would first sort records by City and then by state.
We could then scroll through the database and find, say, 19 instances of the city named **Washington** in the US with each record further sorted by state, so that table would appear for those records as:
**View - Zoom**

Menu commands analogous to zoom button commands.

- **Zoom In** - Magnify the view as if seen from a closer distance.
- **Zoom Out** - Reduce the view as if seen from farther away.
- **Zoom To Fit** - Zoom so that the component fits within the current window size.
- **Zoom To** - Zoom to a given zoom level, expressed as a specific scale if the component is projected.

When zooming with images, zoom in and zoom out will zoom to discrete zoom levels. To zoom to a particular level, use the **View - Zoom To...** menu command. The **Zoom To** menu command allows zooming to a particular scale when components are projected.

Images and surfaces will include a **Native** option in the **Zoom To** choices that will zoom the image so that one image pixel is one screen pixel. The **Native** option with drawings is the only **Zoom To** choice available in unprojected drawings. Project the drawing into some convenient projection for choices of specific scales.

See also the Zoom combo in the navigation toolbar to rapidly zoom to some specific zoom scale.

When zooming, each zoom step will be made using the **Zoom magnification factor** specified in the Tools - Options - User Interface dialog. This factor specifies the change in magnification to use when zooming in or out in the range from 1.1 to 4.0. The default value is 2.0.

**Scroll Wheel**

When using a mouse with a scroll wheel we can use the scroll wheel to zoom in and out. This works even in the middle of commands such as the Edit Toolbar editing commands. By default the zoom will be centered on the mouse position. Holding the **CTRL** key while operating the scroll wheel will force the zoom to be near the center of the opened window.

**Comparison to Edit - GoTo**

To zoom to a particular selection, an address or many other options, use the Edit - GoTo command.

**The ALT Key and Zoom**

Pressing the **ALT** key when using either **Zoom In** or **Zoom Out** will toggle zoom function in/out. For example, holding down the **ALT** key when the **Zoom In** command will have the same effect as **Zoom Out**. This use of the **ALT** key allows us to choose either **Zoom In** or **Zoom Out** and then rapidly browse by clicking with the mouse with the right hand and using the **ALT** key with the left hand to zoom in or out as desired. [Or vice versa if you are left handed.]

**Note:** The **ALT** key works as described above only if Snap modes are not on.

**CTRL Zoom Shortcut**

Pressing the **CTRL** key and the * asterisk key on the numeric keypad at the same time will zoom an image to native zoom, with one image pixel equivalent to one screen pixel.

**Matching Scale**

In the Tools - Options dialog check the **Adjust display scale for monitor resolution** box. That will match the scale used in Manifold to what is literally shown on the monitor given monitor size, DPI and other factors.
When working with layouts we can then choose **View - Zoom to** and choose a zoom of 1:1 so that the layout is shown exactly real size. If we have a large enough monitor we can then see the layout exactly as it will be printed with, for example, an A4 sized paper layout being displayed as a full-sized A4 sheet of paper on the monitor.
The **View - Graticule** command displays or creates a grid of lines that are parallel to meridians of longitude and parallels of latitude. Graticule lines will be curved in geographic projections.

Graticules may be shown as system items in the window or may be saved as objects into a drawing. Graticules may also be used with Snap to precisely locate map clicks.

- **Show Graticule**: Check box to show graticule.
- **From / To**: The beginning and end Longitude and Latitude values the graticule should span.
- **Spacing**: Longitude and Latitude spacing of graticule lines.
- **(Units box)**: Not enabled for graticules, which always use degrees.
- **Same Spacing**: Check so that any change in Longitude spacing will update Latitude spacing as well and vice versa. Use if the same Longitude and Latitude graticule spacing is desired.
- **Segments**: The number of coordinates to use per graticule line. More segments will allow for smoother curves if lines created with graticules are projected.
- **Style**: Graphics style used to show graticule.
- **Size**: Width of line in printer's points to use for the graticule line.
- **Suggest**: Load suggested defaults for the current view.
- **Create**: Create actual line objects in the drawing for the grid. Use carefully, since every press of the Create button will create another set of lines.

Most "whole world" graticules are laid out from -180 to 180 degrees Longitude and from -70 to 70 degrees Latitude in spacing of 10 degrees. This provides a pleasing effect when used with maps of the entire Earth.

If a very large number of graticule cells (greater than 10000) would be created given the specified settings, Manifold will ask for a confirmation in case of error.

### Creating Graticules as Objects

The graticule that appears when the **Show Graticule** box is checked is not part of any layer. It is something created by the system and overlaid upon the map window. It does not really exist and cannot be selected or otherwise manipulated. The default graticule color is set by an option in Tools - Options.

We frequently will want to create actual objects, lines, in the form of the graticule to allow us to better manipulate the graticule in graphics arts effects. For example, we might wish to position the graticule in a drawing layer in a map so that it is above some layers (oceans objects) and below others (continents). Alternately, we might want to select some of the lines that make up the graticule and delete them so we have a graticule in some places but not in others. This is of interest sometimes to create a proper appearance when using "interrupted" projections.

To create line objects, set up the graticule as desired in the **View - Graticule** dialog and then press the Create button. The graticule will be created in the active drawing as line objects. These may then be manipulated like any other lines. In maps it is often convenient to first create a new blank drawing with a right click on a layer tab and using **Add - New Drawing**, to rename the new drawing "graticule" and to then create the graticule in that layer.

**Example**
If we create a graticule on a world map (seen in \textit{Latitude / Longitude} projection) it will overlay all objects in the map. The graticule shown extends from -180 to 180 degrees longitude and from -70 to 70 degrees latitude using a spacing of 10 degrees.

We can use \textbf{Add - New Drawing} to create a new drawing and then create a graticule by pressing the \textbf{Create} button in the \textit{View - Graticule} dialog.

To see the new set of graticule lines, we uncheck the \textbf{Show Graticule} box in the dialog (otherwise, the graticule shown by the system will precisely overlay and thus hide the new graticule just created). We can move the new drawing to a layer below the world map drawing and change the color of the lines in the graticule.

\textbf{The Difference between Graticules and Grids}

Graticules are always expressed in geographic coordinates (latitude and longitude) while grids are expressed in the native X and Y coordinates of the coordinate system of the component. For components using the \textit{Latitude / Longitude} “non-projection”, both graticules and grids will appear as a grid of horizontal and vertical straight lines.

In projected coordinate systems, graticules will be created as curved lines (if necessary) to parallel the curved form of meridians of longitude or parallels of latitude in the projection. Grids, however, will always appear as a grid of horizontal and vertical straight lines.

In the image above a drawing of a world map is shown in \textbf{Robinson} projection with a graticule in magenta and a grid in blue. Note that the graticule has curved meridians while the grid uses straight lines only.
**Tech Tip**

Interrupted projections are not continuous coordinate systems. They employ multiple conversion domains with blank space between the different lobes of the conversion domains, as seen in the illustration below of the Mollweide Interrupted projection.

![Mollweide Interrupted Projection Illustration](image)

It is absolutely essential to check the **Clip Coordinates** box in the **Projection** dialog whenever using such projections. This box causes Manifold to clip each object so that it exists only within the allowed conversion domain lobes and does not extend or cross through disallowed blank space. This is a highly computationally intensive process so the **Clip Coordinates** box is not checked by default, so that significant overhead is not imposed if it is unnecessary.

Dealing with the separate conversion domain lobes of an interrupted projection requires a manual approach to creating graticules, since the graticule lines normally extend through the blank space between lobes. Use the following procedure:

1. Create a latitude / longitude drawing.
2. Use the **View - Graticule** tool to create the desired graticule, using the option to **Create** the graticule as line objects.
3. Project the drawing into the desired interrupted projection, making sure to check **Clip Coordinates**.
4. Edit the graticule lines by selecting undesired lines and deleting them, or by adding lines.

For many uses the fastest method is to add lines. Let's consider an example of creating a graticule for use with **Mollweide Interrupted**. Suppose we begin with a latitude / longitude drawing in which a graticule was created with lines every 10 degrees from -180 to 180 longitude and from -70 to 70 latitude.

![Graticule Illustration](image)

After projection into Mollweide Interrupted with **Clip Coordinates** checked, the lines that appear on the edges of the conversion domain lobes will have been deleted.
We can add lines by clicking Snap To Lines and then using the Insert Line tool to add lines between the "dangling" parallels. This goes very rapidly with less than a minute required to complete the graticule.

The result will be a graticule grid with lines restored that were deleted by Clip Coordinates. This procedure was used to create the graticule seen in the interrupted projection illustration above.
View - Grid
Show a grid of horizontal and vertical lines that may be used as a guide when editing. Grids are often used with Snap to precisely locate mouse clicks. The default color for grids is set in Tools - Options.

Usage with drawings, images, surfaces, labels and maps

In drawings, images, surfaces, labels and maps the View - Grid dialog provides the following options:

- **Show Grid**: Check box to show grid.
- **From / To**: The beginning and end X and Y values the grid should span.
- **Spacing**: X and Y spacing of grid lines.
- **(Units box)**: Choose units to be used.
- **Same Spacing**: Check so that any change in X spacing will update Y spacing as well and vice versa. Use if the same X and Y grid spacing is desired.
- **Segments**: The number of coordinates to use per grid line. More segments will allow for smoother curves if lines created with grids are ever projected.
- **Style**: Graphics style used to show grid lines.
- **Size**: Width of line in printer's points to use for the grid line.
- **Suggest**: Load suggested defaults for the current view.
- **Create**: Create actual line objects in the drawing for the grid. Use carefully, since every press of the Create button will create another set of lines.

Default settings for the above options will be presented that cover the current view with a grid, using what are likely to be reasonable settings for stepping.

If a very large number of grid cells (greater than 10000) would be created given the specified settings, Manifold will ask for a confirmation in case of error.

Usage with forms and print layouts

In forms and print layouts, the Grid dialog provides a simpler set of controls, since the grid is automatically created over the entire layout or form:

- **Show Grid**: Check box to show grid.
- **Step by X**: X (horizontal) spacing of grid lines in the given units.
- **Step by Y**: Y (vertical) spacing of grid lines in the given units.
- **(Units box)**: Choose units to be used.

Creating Grids as Objects

The grid that appears when the Show Grid box is checked is not part of any layer. It is something created by the system and overlaid upon the map window. It does not really exist and cannot be selected or otherwise manipulated. The default grid color is set by an option in Tools - Options.

We frequently will want to create actual objects, lines, in the form of the grid to allow us to better manipulate the grid in graphics arts effects. For example, we might wish to position the grid in a drawing layer in a map so that it...
is above some layers (oceans objects) and below others (continents). Alternately, we might want to select some of the lines that make up the grid and delete them so we have a grid in some places but not in others. This is of interest sometimes to create a proper appearance when using “interrupted” projections.

To create line objects, set up the grid as desired in the View - Grid dialog and then press the Create button. The grid will be created in the active drawing as line objects. These may then be manipulated like any other lines. In maps it is often convenient to first create a new blank drawing with a right click on a layer tab and using Add - New Drawing, to rename the new drawing “grid” and to then create the grid in that layer.

Example

If we create a grid on a world map (seen in Latitude / Longitude projection) it will overlay all objects in the map. The grid shown extends from -180 to 180 degrees longitude and from -70 to 70 degrees latitude using a spacing of 10 degrees.

We can use Add - New Drawing to create a new drawing and then create a grid by pressing the Create button in the View - Grid dialog.

To see the new set of grid lines, we uncheck the Show Grid box in the dialog (otherwise, the grid shown by the system will precisely overlay and thus hide the new grid just created). We can move the new drawing to a layer below the world map drawing and change the color of the lines in the grid.

The Difference between Graticules and Grids

Graticules are always expressed in geographic coordinates (latitude and longitude) while grids are expressed in the native X and Y coordinates of the coordinate system of the component. For components using the Latitude / Longitude "non-projection", both graticules and grids will appear as a grid of horizontal and vertical straight lines.

In projected coordinate systems, graticules will be created as curved lines (if necessary) to parallel the curved form of meridians of longitude or parallels of latitude in the projection. Grids, however, will always appear as a grid of horizontal and vertical straight lines.
In the image above a drawing of a world map is shown in **Robinson** projection with a graticule in magenta and a grid in blue. Note that the graticule has curved meridians while the grid uses straight lines only.
**View - Legend**

A **Legend** is a small display that summarizes formats used in a drawing, surface, image, labels component or map. By default, a legend shows object samples in a column to the left with a text caption describing each object sample to the right. Legends are tied to the component for which they are created. Manifold will remember the legend settings for that component.

**See Also**

Adding Legends

**Legends**

Adding a Legend
View - North Arrow

Display an arrow pointing North using a choice from various compass arrow styles.

Show north arrow  Check to display north arrow.

Align  Positioning of the north arrow: Left Bottom, Left Top, None, Right Bottom or Right Top. If None, the north arrow can be dragged to different locations.

Style  Choose from various graphical styles.

Bearing  Rotate the arrow by the given number of degrees. Very unwise to do except in special situations.

Size  Size in points.

Colors  Foreground and background colors for the north arrow.

Font  Font control for N, S, E and W letters that appear in some styles. Use this button to change the font used, the size of the font, etc.

Halo Text  Surround text letters with a halo of background color. Useful to provide a contrasting aura of color that allows letters to stand out no matter if the map behind them is light or dark.

Once a north arrow has been added to a component window, we can right click on it and choose Properties from the context menu to change the above settings.

The Tools - Options - Font dialog allows setting the default font to be used for those styles that include letters.

Legends, north arrows and scale bars can be copied and pasted between components. Copying a particular style of north arrow from an existing component and pasting it into a new component can be significantly faster than configuring a new north arrow from scratch.

Bearing Option

Manifold components are always displayed "North up" based on the assumption that they have been created that way in a geographic context. All correctly georeferenced components will always be "North up" so for every correctly georeferenced component the North Arrow should use a Bearing of 0 degrees.

On rare occasions we may work with drawings or images that are not georeferenced, for example, such as a factory diagram imported from AutoCAD DXF format, and which have not been drawn with "North up." In such
cases and only in such cases if we know the correct orientation for the North Arrow, we can use the Bearing value to provide a North Arrow that is not aligned straight up. Instead, the North Arrow will point to North at whatever Bearing rotation has been specified (with the default 0 degrees pointing straight up).

Note that changing the Bearing value does NOT rotate the drawing or map or other component in which the North Arrow is displayed: it simply rotates the North Arrow. Therefore, use of values other than 0 for Bearing is always a mistake for components that are correctly georegistered.

**Adding a North Arrow to a Print Layout**

See the Legends, Scale Bars and North Arrows in Layouts topic.
View - Scale Bar
Display a scale bar that shows the current scale of the map.

---

Show scale bar  Check to display scale bar.

Align  Positioning of the scale bar: Left Bottom, Left Top, None, Right Bottom or Right Top. If None, the scale bar can be dragged to different locations, but the bar can end up out of sight after pan or zoom operations. Using positions other than None always positions the bar relative to the open window or print layout to guarantee it stays in sight.

Style  Choose from various graphical styles.

Colors  Foreground and background colors for the scale bar.

Font  Settings for font used with those styles that include text.

Halo Text  Surround text letters with a halo of background color. Useful to provide a contrasting aura of color that allows letters to stand out no matter if the map behind them is light or dark.

Display  Number of units in the given units of measure. For example, if we wanted the scale bar to show 100 kilometers we would enter 100 and choose kilometers as the unit of measure.

Unprojected maps will allow only angular measures such as Arc Minutes, Arc Seconds, Degrees and Radians as units of measure.

Projected maps will allow a wide variety of standard linear units of measurement (including numerous international units of measure).

at least  Make the scale bar no smaller than this size in points.

at most  Make the scale bar no larger than this size in points.

Change color on underflow or overflow  If the units of measure and required display would force the scale bar to be smaller than the at least setting or
larger than the at most setting, change the color of the bar to show that it is out of range.

Once a scale bar has been added to a component window, we can right click on it and choose Properties from the context menu to change the above settings.

Scale bars are only approximations when large geographic regions are shown. To minimize distortion, use a projection that minimizes scale distortion.

Legends, north arrows and scale bars can be copied and pasted between components. Copying a particular style of scale bar from an existing component and pasting it into a new component can be significantly faster than configuring a new scale bar from scratch.

**Overruns and Underruns**

If the units of measure and required display would force the scale bar to be smaller than the at least setting or larger than the at most setting the scale bar will prepend a “>” or “<” character to the scale value.

**Adding a Scale Bar to a Print Layout**

See the Legends, Scale Bars and North Arrows in Layouts topic.

**Troubleshooting**

If a scale bar does not change size when the Display number is changed or if it otherwise misbehaves, consider if the number of units to display would cause the scale bar to be less than the minimum size specified (an underflow) or larger than the maximum size specified (an overflow).
View - Structure
The View - Structure menu choice allows us to show the enclosing box of objects and other structural details visually in drawings and labels components.

Use with Drawings

Check options to display them in the drawing window.

- **Object Boxes**: Show the minimum enclosing rectangle for each object.
- **Object Centroids**: Show the coordinate centroid for each object.
- **Branch Boxes**: Show the outlines of the minimum enclosing rectangles that enclose different branches of multi-branched objects.
- **Branch Centroids**: Show the coordinate centroid for each branch of multi-branched objects.
- **Inflection Points**: Show the location of coordinates (inflection points) that define an object.
- **Segment Points**: Show the midpoint of line segments (the straight portions of lines between the coordinates that define lines) in lines and the borderlines of areas.

Examples in Drawings

We begin with four objects, a multi-branched area (containing branches that represent "holes"), a single-branched area (an ordinary triangle), a line and a point. The illustrations show the result of each Structure option:
Use with Labels Components

Check options to show the object box outlines and tie points for labels in a labels window.

Object Boxes  Show the outline of the rectangular box that encloses the label text.
Tie Points  Show the tie point to which points labels are anchored.

Tie Lines  Show the tie lines to which line labels are anchored.

The object boxes and tie points and tie lines appear only in a labels component window. They are used to see the alignment of labels text relative to tie points.

Suppose we have a text label that consists of several lines of text.

Open the book to the first page and begin scanning words from left to right until their meaning is understood.

If we enable Object Boxes we see the outline that encloses the text. [We use a rather lengthy text label in this example because it shows the object box better.]

Open the book to the first page and begin scanning words from left to right until their meaning is understood.

If we enable Tie Points we see the tie point to which the text is bound and relative to which it is positioned.

Open the book to the first page and begin scanning words from left to right until their meaning is understood.

See the Aligning Labels topic for additional illustrations of tie points and tie lines.

Align Controls

The Align controls in the Format toolbar adjust the position of the label object box relative to the tie point for the label.

Align Left

Center Horizontally

Align Right

Align Top

Center Vertically

Align Bottom
The left-center-right and top-center-bottom buttons can be combined, for example, to create a right-bottom alignment.

**Note**

The text in the multiline label is taken from the "How to Use This Book" section of Mr. Bunny's Guide to ActiveX, by Carlton Egremont III, ISBN 0-201-48536-2. One of the funniest programming texts ever written, this slim volume presents ActiveX concepts in the form of conversations between a cartoon rabbit and farmer.

**See Also**

Aligning Labels

**Drawings - Object Coordinates**

**Editing Objects**
View - Full Screen
Display main Manifold window using the entire monitor screen, eliminating the title bar and menu bar. Press **F11** to enter full screen mode. Press **F11** again to exit full screen mode.

If toolbars are hidden using **Tools - Customize** and a window is maximized the result is a "full screen" display.
View - Refresh Data

Enabled for linked components such as linked drawings or linked tables and queries so that the linked component or query can be refreshed from the originating table. When the geocoded table controlling a linked drawing changes, the linked drawing will not be updated automatically within an interactive session of Manifold. Instead, the Refresh Data command must be issued.

When linked components are used in a Manifold IMS session we can set the Refresh linked components... parameter to some automatic interval, so Refresh Data is not necessary in IMS work.

Invoking the View - Refresh Data command on a query will cause cascaded refreshes within all dependent queries and linked tables.

Example 1

We have a linked table T and a query Q that selects some data from T. We run Q and it displays the resulting data.

We then you go to some other program and modify T outside of Manifold. Re-computing Q with View - Refresh Data will now first refresh T and will then recompute Q on the updated data in T.

Example 2

We have a native table T, a query S that selects some data from T and a query Q that selects some data from S. We run Q (in turn running S) and it displays the resulting data.

We then modify T so S returns a different set of records. Re-computing Q with View - Refresh Data will first re-compute S and then re-compute Q on updated data from S.
View - Refresh / Autorefresh View
Sets the redisplay behavior of windows and dialogs in Manifold.

**Autorefresh View**  
Refresh all windows on any change.

**Refresh**  
Used to manually refresh windows if Refresh Auto is OFF.

---

When working with very large maps and performing a series of steps, we might not be interested in viewing intermediate results if the price we pay is waiting for all windows to refresh with each step. In that case we can turn **Autorefresh View OFF** and then press **Refresh** once at the end of the procedure.

For example, when selecting objects using the query toolbar in very large drawings it can take a longer time than we would like for the system to redisplay the drawing using red selection color for each selected object. If we are selecting objects with the query toolbar just to delete them, we can save time by switching **Autorefresh View off**. We can then make a selection and delete the objects without waiting for the system to redisplay the drawing.

---

**Tech Tip**

While turning **Autorefresh View off** is very useful in some cases, be careful to turn this option back on when the tasks calling for suppression of autorefresh are finished. Otherwise, it is very easy to forget to turn it back on and later wonder why selections, etc., are not appearing as expected.
View - Display Options

The View - Display Options dialog specifies parameters used to control the appearance of components. When used with labels, the dialog allows us to specify how labels will be displayed or clipped from display. With surfaces, the dialog controls how the surface will appear when opened in a surface window or used as a layer in a map. With images, the dialog allows us to choose which channels of a multi-channel compressed image will be used for R, G, B and Alpha channels.

If the optional Surface Tools package is installed the dialog will also be available to control display options for profiles and elevations. See the Profiles and Elevations topic for more information.

Surface Display Options

By default, surfaces will appear as shaded surface renderings with the color of each pixel corresponding to the data value at that spot as adjusted for highlights and shadows from a Sun in the East. Other options include display of aspect or slope, or use of shading. See the Surface Display Options topic for examples, including details on using fixed interval palettes and customization of palettes. Palette controls are similar to those used in Thematic Formatting of drawings.

**Display**

Choose the computation used to display the surface in 2D.

- **Height** - Color each surface pixel by its height.
- **Aspect** - Color each surface by its aspect, that is, the azimuthal direction in which a tangent plane faces at that spot, for example, a north-facing section of hillside.
- **Slope** - Color each pixel by the inclination of the surface at that point. Slopes are computed using a weighted two-directional slope algorithm. Slopes are given in degrees.

**Palette**

Preset color combinations that may be applied to surfaces. Press **Apply** to apply the preset to the surface. Presets use a fixed number of intervals and corresponding colors.

- **Apply** - Apply the chosen palette preset to the Colors pane. This allows scrolling through the presets without changing colors until we press **Apply**. Pressing **Apply** only changes the color scheme in use for values. It does not change the formatting of the surface until the **OK** button is pressed.
- **Reverse** - Reverse the formats used in the colors box from high to low.
- **Interpolate** - Change the colors or sizes used in the colors boxes by interpolating between the top and the bottom boxes. A quick way of creating smooth gradients of colors.
- **Lighten** - Lighten all colors. Each click on the Lbutton lightens the colors a bit more.
- **Darken** - Darken all colors. Each click on the button darkens the colors a bit more.
- **Grayscale** - Convert all colors to grayscale.

- **Load from File** - Load a previously saved theme from an XML file. Works with all field types except lookup fields. See the Custom Palettes and Themes topic for information on how the XML file is structured.
- **Save to File** - Save this theme to an XML file. Works with all field types except lookup fields. See the Custom Palettes and Themes topic for information on how the XML file is structured.
**Shading** Shade the surface with highlights and shadows as if illuminated by the Sun from a given azimuth and elevation.

**Autocontrast** Automatically adjust contrast for even dispersion of light and dark tones.

**Azimuth** The angle to the Sun's position in degrees from North: North = 0, East = 90, South = 180 and West = 270 degrees. Keep in mind that in the Northern Hemisphere the Sun traverses azimuthal angles from East to South to West, but never North. Used to compute shading.

**Altitude** The Sun's altitude above the horizon in degrees. 0 is at sunrise or sunset and 90 is directly overhead. Used to compute shading.

---

**Display Options for Compressed Images**

The display options dialog appears when a compressed image window is open. Display options are not used for other types of images.

Compressed images are displayed as though they were RGBA images assigning channels from the compressed image data to R, G, B and Alpha channels.

(\text{Channel information}) The number of channels available in the image.

- **Red** Image channel to be used for red color.
- **Green** Image channel to be used for green color.
- **Blue** Image channel to be used for blue color.
- **Alpha** Image channel (if any) to be used for alpha channel transparency.

For an interesting effect, open the display options dialog for a compressed image and assign one of the image's channels to be used for the Alpha channel.

For more information on image display channels, see the Images and Channels topic as well as the RGBA Pixel Transparency topic.

---

**Display Options for Elevations**

Elevations are optional components that are available when the Surface Tools package is installed. See the Profiles and Elevations topic for more information.

- **Shade background** Color the background of the elevation using the same palette (if any) used to color the parent surface. On by default.

- **Display coordinates** Display dots at the location of each coordinate that defines the line used as a profile.

- **Include zero height** Show the entire range of elevations for the surface, from zero to the highest in the elevation display. Off by default, so that the full range of the elevation display is used to show the heights within the elevation only.

- **X axis (distances)**
Label coordinates Draw vertical lines and label the X axis at each coordinate that defines the profile line. Off by default.

Label even values Draw vertical lines and label the X axis at even values of distance. On by default.

Decimal digits The number of digits past the decimal point to show in labels on the X axis. The default value of 0 results in no digits past the decimal point.

Y axis (heights)

Label coordinates Draw horizontal lines and label the Y axis at each coordinate that defines the line used as a profile. Off by default.

Label minimum / maximum Draw horizontal lines and label the Y axis at the minimum and maximum values of height that occur in the profile line. Off by default.

Label surface breaks Draw horizontal lines and label the Y axis at the numeric values that define interval breaks in the palette used to color the surface. Off by default.

Label even values Draw horizontal lines and label the Y axis at even values of height. On by default.

Decimal digits The number of digits past the decimal point to show in labels on the Y axis. The default value of 0 results in no digits past the decimal point.

Display Options for Profiles

Profiles are optional components that are available when the Surface Tools package is installed. See the Profiles and Elevations topic for more information.

Display coordinates Display dots at the location of each coordinate that defines the line used as a profile.

Decimal digits in heights The number of digits past the decimal point to show in the Info pane for average, minimum and maximum heights when the focus is on this profile.

Labels Display Options

The View - Display Options dialog may be launched when a labels component has the focus. The dialog allows us to specify how labels will be displayed or clipped from display. The unit of measurement employed is the printer's point unit used in printing.

Point Labels Point labels are those used for points and for areas.

Offset X … points Distance in points in X (horizontal) displacement from the anchor point of the label. Increase distance to position labels farther away from the anchor point and to accentuate the effect of label alignment settings. 0 by default. Not used if alignment buttons are set to place the label directly upon the point.

Offset Y … points Distance in points in Y (vertical) displacement from the anchor point of the label. Increase distance to position labels farther away from the anchor point and to accentuate the effect of label alignment settings. 0 by default. Not used if alignment buttons are set to place the label directly upon the point.
Callouts Draw a line from the label to each point from which the label is generated.

Minimum length When a callout line is used, do not show it unless it is at least this long.

Optimize horizontal alignment Alter the horizontal alignment of labels to improve the positioning of labels.

Optimize vertical alignment Alter the vertical alignment of labels to improve the positioning of labels.

Line Labels Line labels are those used for lines.

Offset … points Distance in points that a line label should be offset from a line. 0 points by default.

Character Spacing Extra distance between characters in the line label text.

Label each branch If checked (default), will place a line label on each branch of a multi-branched line. If not checked, will place a line label only on the longest branch.

Multiple labels per branch If a particular line's branch is long enough, label it with multiple, repeating labels. This is useful for long lines.

Spacing The minimum spacing between multiple labels on the same branch of a line.

Orient labels left-to-right If checked (default), Manifold orients each label bound to a line to read from left to right as shown on the screen. When the option is turned off, Manifold orients each label so it flows from the beginning of the line to the end of the line.

Resolve overlaps between labels If checked (default), automatically hide some labels so that labels do not overlap.

Spacing Space allowed between labels in points before overlap resolution, when enabled, will take effect. Default is 1 point.

See the Label Display Options topic for details and examples.

Panes

View - Panes

Panes are sub-areas of main windows. They are often used within a main window to keep some information in view while another part of a window shows a changing display.

Manifold has several panes that can either be docked into the main Manifold window or that may be left undocked to float about “always on top” as independent dialogs. Panes may be opened and closed within the View - Panes menu. Panes may also be closed by clicking the X box in their caption bars.

Call Stack Display and manage the scripting engine's function call stack. Used to debug scripts.

Control Points Control points are used georegister images and drawings. The Control Points pane provides a listing of control points defined in the current image or drawing.

Errors Reports errors arising from compilations of .NET language scripts.

GPS Console Provides interactive control over a GPS (Global Positioning System) device connected to the computer.
via a serial port, including moving map functions and fetching information from the GPS.

**History** Displays a running history of actions and results.

**Info** Reports useful information about the active layer or window.

**Layers** Displays the layer stack in a map and allows specification of layer restrictions. The layers pane is more convenient to use with many layers than the tab controls at the bottom of the map.

When used with image windows, the layers pane turns individual R, G, B or alpha channels on and off and also controls whether the image border or background is displayed.

When used with print layouts the layers pane shows the vertical ordering of elements in the layout.

**Notes** A text dialog box allowing user entry of text notes and commentary. As the focus changes from one component window to the other, the contents of the Notes pane will change to the notes made for that component.

**Project** Shows all components in our project. It also shows how components are associated, such as a drawing and its table. We can use the project pane to open components in windows, to drag and drop components into maps, to rename components and to organize components within folders. The status area at the bottom of the pane will provide summary information about any highlighted component.

**Review** Interactive dialog used to resolve conflicts arising from multi-user editing.

**Selections** Provides a scratchpad for saving selections that have been made so that they may later be re-used.

**Tool Properties** Displays settings for the current tool in use, for example, threshold for Select Touch when selecting pixels within images or the opacity of a paintbrush when editing images.

**Variables** Display and manipulate variable values within scripts. Used to debug scripts.

**ViewBots** ViewBots are one-line analytic instruments that report a result or otherwise make a calculation using the contents of a window.

**Views** Saves specific views into a window at a given location and zoom level under a name. At any time we can jump directly to that view by clicking on its name.

**Watches** Watches are one-line dynamic instruments that watch and report upon values of variables in scripts or other process parameters. They are used to debug scripts by signaling watched-for conditions.

**World** The world pane allows setting linked views and position reticules and also shows the current location of the active window on a small world map.

Most users will leave one or more panes open while working with maps and tables. A typical setup would leave Selections, Info and ViewBots panes open on one side of the display with a Layers pane docked to the other side of the display. (This assumes we have a reasonably modern computer system with a larger screen and high-resolution display).

Panes will automatically become enabled or disabled as the focus switches between different windows. For example, the Layers pane is active only when a map window, image window or drawing window has the focus.
As the focus switches between different windows, panes will automatically be loaded with the correct information for that window. For example, the Selections pane will change to show the correct saved selections for whatever window has the focus.

Docking and Undocking

Panes can be docked into the main Manifold Window. Drag and drop a pane onto one of the main Manifold window’s borders to dock it. Panes may be docked into the upper, lower, left or right borders of the main Manifold window.

To undock a docked pane, double click on its margin. It will undock itself.

When a pane is dragged near to or on top of a margin using a click and drag, it will automatically dock itself. To override this, use a CTRL click and drag. This will allow us to drag a pane over top of a toolbar row or near to a window margin without the pane docking itself.

Manifold Keyboard Shortcuts for Panes

In addition to the standard Windows keyboard shortcuts, Manifold provides a set of keyboard shortcuts for opening/closing panes.

ALT-SHIFT-(letter) Show or hide a pane. Press the keyboard combination at any time to open or close a particular pane. The letter used is usually a mnemonic for the first letter of the name of the pane as shown below.

K Call Stack
C Control points.
E Errors
G GPS Console
H History
I Info
L Layers
N Notes
P Project
R Review
S Selections
T Tool Properties
A Variables
B ViewBots
V Views
W Watches
O World

ALT-SHIFT keyboard shortcuts are very important for turning panes off and on when working with systems that have small screens. If your screen display area is limited in size it will be inconvenient to open panes and leave them open because they will cover up too much of the active window. ALT-SHIFT shortcuts will allow you to instantly pop open a pane when needed and to make it vanish when it is not needed.
These shortcuts are listed in the View - Panes menu next to the pane they control.

**Autohide / Popup Panes**

Panes used for controls can be minimized when docked so that they autohide themselves when not in use and automatically pop open when the mouse cursor moves over their tab. Virtually every experienced Manifold user employs this feature to maximize the amount of screen area available for working with component windows.

Consider a Manifold workspace open with the project pane docked in its usual position.

Clicking on the Minimize control for the project pane will minimize the project pane into a small tab on the right-hand margin.
This frees up a lot of screen real estate for use with windows.

Moving the mouse cursor over on top of the project pane's tab (no need to click the tab)...
...will expand the project pane.

As long as the mouse cursor stays over the project pane it will remain expanded. As soon as the mouse cursor moves away from the project pane the pane will collapse again to a small tab.

Using autohide panes is a great way to maximise the available working area on a computer monitor. Consider, for example, the above view in which the project pane has collapsed into a small tab. In this view the active window has been maximized so that it uses all available space.
When open the project pane consumes much area which would be useful for work in the main component window. Although it is true that this example uses artificially small Manifold sessions (sized to fit reasonably as illustrations), even in the case of large, high-resolution monitors it makes sense to save work area if panes are not immediately needed.

**Ending Autohide / Popup Mode**

To end auto hide mode simply click on the pane's tab or click on the pane's caption. This will restore the pane to full size and will end autohide mode. In addition, although Manifold will remember autohide settings for future sessions, opening a new project will cancel autohide mode for the project pane. This allows the project pane to be immediately available for component usage as a new project is opened.

**Notes**

These illustrations show only the project pane. Most experienced Manifold users will have several panes open when working with projects. In such cases autohide capability is even more useful, because it enables multiple panes to be kept available as minimized tabs. When needed, each pane can expand to fit the entire space available for panes with a simple mouseover.

**See Also**

Panes may be rapidly turned on and off using the Tools - Customize dialog, which is especially useful when many panes at once must be turned on or off.

**Historical Note**

Manifold's autohide / popup panes capability originated in the July, 2007 User Meeting held in London, hosted by University College London (UCL) and attended by user community representatives from the US and Europe as well as by manifold.net factory representatives.

Dr. Muki Hakley of UCL presented a session on Usability Issues in GIS, in which he emphasized the importance of maximising available screen "real estate" for active workspace and not consuming a high percentage of the screen on displays of possibly infrequently-used controls. The presentation was based on the results of UCL research using sophisticated equipment to track the eye motions of users operating different GIS packages. Manifold scored much better in his reckoning than older GIS packages, but there was nonetheless room for improvement.

For the sheer fun and power of it, the User Meeting participants agreed to choose "something cool" to implement as a joint decision in Release 8, even though the release was only a few short weeks from publication. Dr.
Hakley's presentation was so well received and so persuasive that the consensus was clearly for implementing popup panes. And so they were implemented in the final stages of the Release 8 beta campaign.
View - Panes - Call Stack

The **Call Stack** pane is enabled when the Manifold Debugger is installed.

The Call Stack pane is used to display and manage the scripting engine's function call stack. It is used to debug scripts under the control of the debugger. Each row in the Call Stack pane shows a call.

- **Go To** - Enabled when a call within the Call Stack pane is highlighted. Go to that call. Double-clicking a line within the Call Stack pane is a shortcut to **Go To** that call.

- **Show Module** - Press in to show module (script) names for each call.

- **Show Line** - Press in to show the line number for that call within the module.

- **Show Line Position** - Press in to show the position within the line for that call. Useful when there is more than one call on the same line.

- **Show Language** - Press in to show the language used for each module.

For example, suppose we've stopped execution in a script called **A** at a breakpoint where another script is run.

```vbscript
Sub Main
    Set components = Application.ActiveDocument.ComponentSet
    Set anotherScript = components(components.ItemByName("B"))
    anotherScript.Run
End Sub
```

With all of the **Show** buttons pressed in, the Call Stack pane will report the following values:

If we click on the single call line shown within the Call Stack pane we can enable the **Go To** button. This is not particularly useful in such a simple example (since we are already at that call) but when the Call Stack pane shows many calls we can click on any of them to highlight it and to jump execution to that call.

**See Also**

See the Debugger topic for an example of using the Call Stack pane. Other panes used with the debugger include:

- Variables
- Watches
View - Panes - Control Points

Use the Control Points pane to add new control points to a drawing, image or map. Control points are used to georegister an image or drawing to the same geographic location and projection used by a "known good" image or drawing.

<table>
<thead>
<tr>
<th>Name</th>
<th>X / Longitude</th>
<th>Y / Latitude</th>
</tr>
</thead>
<tbody>
<tr>
<td>Controll</td>
<td>-122.480997</td>
<td>37.811238</td>
</tr>
<tr>
<td>Control2</td>
<td>-122.048519</td>
<td>37.467911</td>
</tr>
</tbody>
</table>

The Control Points pane always shows a list of control points defined for the active image or drawing together with their coordinates. When we click on a different window the Control Points pane will switch context to show any control points defined for the active window.

The Control Points pane is also used to rename control points or to change their location by changing their coordinates. We can click into the Name field to change the name from the defaults, if desired. To change the coordinates of a control point we click into their X / Longitude or Y / Latitude fields.

- **New Control Point** - Add a control point by clicking with the mouse in the component window. A new control point will be added in the Control Points pane.
- **New Blank Control Point** - Add a blank control point row in the Control Points pane.
- **Delete Control Point** - Delete the highlighted control point. More than one control point may be highlighted by clicking on a starting point and then SHIFT-clicking on the ending point to highlight the starting and ending point and all points in between. All the highlighted points may then be deleted.
- **Register** - Georegister this drawing or image using matching control points in a reference component.
- **Load Points** - Load control points from points that exist in the drawing (enabled for drawings only).
- **Save Points** - Save control points as points in the drawing (enabled for drawings only).
- **Show Names** - Show the names of control points in the component.
- **Preview** - Show control points in the component.

**Name**

Name of the control point. Control points are matched between two components by using their names.

**X / Longitude**

The X or Longitude position of the control point.

**Y / Latitude**

The Y or Latitude position of the control point.

Adding a Control Point to a Component using the Mouse

1. Open the component. Zoom into the location where the control point is to be located if greater accuracy is required.
2. Click on the New Control Point button in the Control Points pane's toolbar.
3. Click the location in the component where you want the control point. It will appear in the drawing and a new control point row with coordinates will appear in the Control Points pane.
4. If you don’t like the name assigned to the control point by default double click onto the name to change it.

No matter what other tool modes are selected (for example, Zoom In or Center), after clicking New Control Point the mouse cursor will temporarily shift modes so that the next click locates the control point. If the mouse is clicked within the component window a new control point will be created. If the mouse is clicked anywhere else the New Control Point mode is abandoned and the mouse cursor will return to whatever state it was in before the New Control Point button was clicked. This is why we zoom in first to the region of interest where we wish to place the control point.

At times we will add new control points manually by specifying their coordinates.

**Adding a Control Point to a Component Manually**

1. Open the component to which the control point is to be added.
2. Click on the New Blank Control Point button in the Control Points pane's toolbar.
3. A new control point row appears with zero coordinates.
4. Double click into the X / Longitude and Y / Latitude coordinate fields to specify the desired coordinates.

**Show Names**

A control point appears by default with a label showing its name. The screen shots above show how control points appear in drawing layers at left and in images at right.

Clicking OFF the Show Names button removes the name labels from the display.

**Georegistration Dialog**

To georegister the active image or drawing, click on the Register button in the Control Points pane.

**Note:** Some options will be enabled only for certain methods or when sufficient control points have been defined.

<table>
<thead>
<tr>
<th>Reference</th>
<th>The name of the drawing or image to be used as a source of control points to be used as reference points.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Method</td>
<td>One of the following algorithmic methods:</td>
</tr>
<tr>
<td></td>
<td><strong>Affine (triangulation)</strong> - Also called geometric transforms, affine methods can georegister a target component to a reference component using fewer control points than required by the Numeric method. However, affine registration requires care in placement of control points.</td>
</tr>
<tr>
<td></td>
<td><strong>Affine (scale, shift, rotate)</strong> - A fast method that is algorithmically equivalent to using Numeric with an Order of 1. This is the default method since it works with any number of control points.</td>
</tr>
<tr>
<td></td>
<td><strong>Simple (scale, shift)</strong> - Match components using XY translation and re-scaling only. Works with any number</td>
</tr>
</tbody>
</table>
of control points.

**Numeric (polynomial)** - Numeric matching uses numerical computation methods to transform one component to match another. A large number of control points are required for good matching but the method is algorithmically simple and fast. Available only when eight or more control points have been defined, thus allowing an order of \( 2 \) or greater.

**Note:** Only those methods usable with the number of control points you have defined will be displayed. If you don’t see a method, add more control points.

**Order**  The level of mathematical sophistication applied. Higher orders result in better matches but take more time and more control points. In numeric methods the highest order exponent used in the polynomial equations generated to transform the coordinate system of the target component. Enabled only for the **Numeric** method.

**Modify coordinate system**  Enabled when the **Simple** method is selected. If checked (default) the coordinate system (projection) of the component being georegistered is converted to the coordinate system of the guiding component. If not checked, the coordinate system is not changed.

**Scale pixels equally in X and Y direction**  When this option is off, the user can specify both the width and the height of the resulting image or surface component. When the option is turned on, the user can only specify the width of the resulting component and the system will automatically compute the height. By default the option is turned on.

**Interpolate pixels**  Enabled when georegistering non-palette images or surfaces using the **Numeric** method. Creates a much smoother image when transforming the image into the new projection. Very computationally expensive: requires approximately twice the processing time to georegister an image if enabled. **Note:** Methods other than **Numeric** always interpolate pixels for non-palette images and surfaces and never interpolate pixels for palette images.

**Save error surface using**  Create a surface containing the root mean square error value for each location in the georegistered component. Choose the data type for the error number saved in the surface at each location. If checked, this option doubles the time required for georegistration. Enabled for the **Numeric** method. See the Error Surfaces topic.

**Size**  The transformed size of the image or surface in pixels. By default this will be set to some value that attempts to approximately preserve the size of the image or surface before georegistration. Enabled for images or surfaces.

The **Order** chosen will have a great impact on the number of control points required, especially when using the **numeric** method. For numeric georegistration, there usually must be at least four times the order number in control points. Thus, for numeric registration of order 4, there must be at least 16 control points. This guideline is a minimum value. Certain arrangements of control points may require an even greater number of control points.

**Affine** registration works with fewer control points, as few as two or three in the case of **Affine (scale, shift, rotate).** However, greater care must be taken when assigning affine control points. In general, control points should be placed for affine registration so that control points are drawn along the outer border of an imaginary shape without control points in the middle of the shape. For example, placing control points in a rectangular or rhomboidal arrangement is OK. Placing control points in a circle with several additional control points in the center of the circle is not OK.

**Affine** registration is a good choice when registering scanned images of maps that have a graticule grid of latitude and longitude lines shown. One can choose four intersections of latitude and longitude graticule lines that are near the four corners of the image to use as control points. Because fewer control points are required affine registration is almost always a better choice if we can place control points in a rectangular or rhomboidal arrangement.
**Numeric** registration may be a better choice when registering images to control points that are scattered throughout the image. When using numeric registration, evenly distributed control points will yield better results. This will, however, usually require many more control points than affine registration.

Either affine or numeric registration is a good choice when registering scanned images of maps that have a graticule grid of latitude and longitude lines shown if we are able to place many control points. One can choose a number of intersections of latitude and longitude graticule lines to rapidly mark many control points.

In either case, if control points are restricted to only part of the image it is quite likely that other parts of the image will not be georegistered well. When used in maps they will appear to be out of alignment with overlying drawing objects. It is critically important to use control points that are dispersed throughout the entire image. With the numeric method, the more control points that are used, the better the ultimate georegistration.

Given the labor of marking many control points the appeal of **Simple** registration is obvious. If an image is already in a North up overhead view and need only be resized and moved to be registered to a given target drawing this is a good choice. If the image is in Orthographic (the default when importing from geographically-unaware formats like .jpg), re-project the drawing into Orthographic and note the central latitude and longitude. Use **Edit - Assign Projection** with the image to specify the same central latitude and longitude. Then use **Simple** registration to georegister the image to the drawing.

**Tech Tips**

Uncheck the *Autoscroll window on edit or selection operations* option in Tools - Options when working with control points, or use the *Require Alt key* so that no autoscroll happens unless the *Alt* key is pressed. Because using the *New Control Point* tool activates the mouse as soon as it leaves the Control Points pane, if this option is not deactivated the target window will begin to autoscroll as the mouse enters it.

Picking a control point within a component window sets the focus to that window.

Large images or surfaces can take a *very long time* to georegister when using **Affine (triangulation)** method or the **Numeric** method with higher **Order**. If desired, the georegistration process can be cancelled and then re-launched using a different method or lower **Order**.

Occasionally we might make a mistake in the placement or naming of control points that results in a bizarre and obviously wrong georegistration. In such cases, it is nice to know that **Undo** will work.

Images must be resized during some types of georegistration. Palette images will always be resized using the nearest neighbor method (no interpolation of colors) to guarantee that the georegistration process does not introduce any new colors.

**See Also**

- The File - Print dialog used to print a component includes a **Control Points** option that may be used to print the control points in a component.
- See the Georegistration topic for details on how to use control points to georegister images and drawings.
View - Panes - Errors

The Errors pane displays the description, module, line and line position of any errors that occur during the compilation phase of running a .NET script. Highlighting an error in the Errors pane and clicking Go To (or, simply double-clicking the error) will open the relevant script component and place the cursor at the location of the error.

The Errors pane will automatically pop open if any errors occur when running the Script - Compile to DLL command.

Go To - Open the relevant script component and place the cursor at the location of the error.

Show Module - Press in to show the module (script) names for each error.

Show Line - Press in to show the line number for that error within the script.

Show Line Position - Press in to show the position within the line for that error. Useful when there is more than one error on the same line.

Example

Suppose we start with the default VB.NET script seen above, which has been named VB.NET Hello.

We introduce an error by changing the first Shared to Snared.
When we compile the script using Compile to DLL an error will be reported and the errors pane will pop open (if it is not yet open) as seen above. Note that the highlighted error text is repeated at greater length in the status text readout at the bottom of the pane.

Double clicking on one of the errors, for example, the top error as seen above, will highlight the error line in the script.
Double clicking the middle error will jump to that line. As is typically the case with errors in programming, one error can generate more than one report of syntax errors as the problem cascades through the text to be parsed.

In this case, double clicking on the first error reported and the 'End Sub' error helps us rapidly identify the mistake.

Error Codes

Error codes reported in the Errors pane are generated by the Microsoft .NET compiler for that language. The easiest way of looking up an error code is to visit the Microsoft MSDN library at http://msdn.microsoft.com/library or http://msdn.microsoft.com and to search for the error code. Regrettably, not all Microsoft .NET compiler error codes are documented in the MSDN site.

For example, a search on BC30188 will fail to turn up an error code while a search on CS1519 (a C# error code often triggered by insertion of an extra curly bracket) will turn up an error code page.

Script - Compile to DLL
View - Panes - GPS Console

Manifold's GPS Console provides interactive control over a GPS (Global Positioning System) device connected to the computer via a serial port or USB connection. The GPS Console allows setting moving map mode or automatically fetching position and other data from the GPS device.

For details on using the GPS Console, see the Working with GPS Receivers topic.

Note: We must have at least one drawing in the project to accept data from the GPS device to use Track commands.

Controls

Connect / Disconnect - Press IN to connect to the GPS device using serial port parameters specified in the GPS properties dialog. The GPS dialog cannot fetch data from the GPS device until it is connected. Connecting to the GPS also serves as a test of the connection.

Track Center - "Moving map" mode: with each reading of data from the GPS receiver move the drawing so that the acquired position of the GPS is always in the center of the currently active window. When Track Center is engaged and either a Track or Track Sequence command is issued the active window will be panned to center on the location reported by the GPS.

Track Line - With each reading of data from the GPS receiver extend a line to the current position. This option creates a line object that shows the sequence of tracked positions.

Track Points - With each reading of data from the GPS receiver create a point at the current position. This option creates a series of points that show the sequence of tracked positions.

Track Columns - Used to choose which names will be used for destination fields of downloaded data. Otherwise, has no effect unless Track Points is selected. Raises a dialog allowing choice of the destination fields within the drawing's table for the various data fields acquired from the GPS receiver. Choose a blank destination in the Save To column to not import a given GPS field. When selected, Track Columns will write the selected data fields into the specified destination fields in the drawing's table with each reading of data from the GPS receiver.

Track - Press to fetch data from the GPS. Each press of this button commands one acquisition of data and the creation of objects or moving map action as specified by the Track Center/Line/Points/Fields buttons.

Track Sequence - Start / Stop acquiring data from the GPS receiver repeatedly using the given time interval between readings. When this button is pressed in, each specified time interval repeatedly commands data acquisition and the creation of objects or moving map action as specified by the Track Center/Line/Points/Fields buttons.

Download Waypoints - Enabled only when connected to a Garmin device using Garmin protocol or when an NMEA device is detected as sending waypoints. Press to download waypoints. Press again to cancel downloading. When pressed, the system will begin downloading waypoints from the GPS receiver, arranging them in order and creating a point object for each waypoint. A line object will be created for a route. To cancel the download process without creating any objects, click the Download.
/ Waypoints button again before the download is complete.

See the Waypoints and Projections paragraph below for important notes on projections.

Upload Waypoints - Enabled only when connected to a Garmin device using Garmin protocol. Press to upload waypoints. Press again to cancel uploading.

Properties - Set up the serial port connection to the GPS receiver by specifying either a USB connection or the serial port used and the serial protocol options required by the GPS receiver.

Drawing
Choose the drawing into which objects and data acquired from the GPS will be placed.

Refresh
Specify the time interval and time units (minutes, milliseconds or seconds) between automatic data acquisition when tracking.

Datum
Datum used by the GPS receiver. The datum setting dialog is resizable.

Altitude
Value reported by the GPS receiver for the height of the GPS antenna. Although handheld GPS receivers integrate the antenna into the instrument case, remember when using an external antenna the GPS device reports the position of the antenna.

Bearing
True heading computed by the GPS receiver for its motion based on differences between recent positions measured. The true heading is the magnetic heading corrected for magnetic variation reported for the current position by the GPS device.

Mag bearing
Magnetic bearing.

Mag variation
Magnetic variation.

Latitude
Current position latitude.

Longitude
Current position longitude.

Quality
Quality of the fix for the current position.

Speed
Speed in centimeters per hour computed by the GPS receiver for its motion based on differences between recent positions measured.

Satellites
The number of GPS satellites in view of the GPS receiver.

(Properties Dialog)

Device
Serial port or USB device to which the GPS receiver is connected. Most computers support COM1 and COM2 with connectors on the chassis. Manifold will automatically search the first 1000 possible COM port configurations and allow use of any COM port that appears to be working. If a USB port is used choose either the Garmin USB connection or the generic USB Human Interface connection if a non-Garmin USB GPS is in use. USB choices will not be available if a USB GPS device is not detected.

Baud rate
Speed of the serial connection. Use 4800 for most GPS receivers.
Data bits
Number of data bits in the serial protocol. Use 8 for most GPS receivers.

Stop bits
Number of stop bits in the serial protocol. Use 1 for most GPS receivers.

Parity
Parity setting for the serial protocol. Use None for most GPS receivers.

Test
Test connection to the GPS receiver. Instructs Manifold to listen for valid NMEA sentences.

Consult your GPS receiver’s user manual for information on what settings to use for the Properties dialog when using a serial port connection. The Properties dialog will fail to launch if there are no available COM ports or USB devices available. Unplugging a USB GPS device will automatically disconnect the GPS Console.

Pressing the Test button in the Properties dialog commands Manifold to try connecting to the GPS to see if it is alive and well and to report, if possible, what protocol the GPS recognizes. If a GPS is found, a message box will pop open to report whether it is using NMEA or GARMIN protocol. If it is using NMEA protocol, Manifold will report the NMEA tags recognized. If it is using GARMIN protocol Manifold will report a list of recognized GARMIN subprotocols recognized as well as the version of each subprotocol. If a GPS device switches from GARMIN to NMEA protocol, Manifold will automatically detect the change.

GPS Columns Dialog

The GPS Columns dialog allows specification of NMEA data that will be downloaded from the GPS, if available. Note that not all GPS devices will transmit all of the following fields. For example, only a depth sounder that repeats GPS location information while transmitting depth information as an NMEA repeater will provide GPS Depth information. The complete list of fields in the GPS Columns dialog is taken from all NMEA sentences that the Manifold GPS Console NMEA parser recognizes.

To capture a given field, double click into the Save To cell for that field and choose either the name of an existing column or to create a new column for that field choose [New Column].

Select All - Capture all fields.
Select None - Capture no fields.
Select Inverse - Uncapture all captured fields and capture all uncaptured fields. A fast way to use all but one field: click Select None, capture the one field not desired and then click Select Inverse.

GPS Air Temperature
Air temperature.

GPS Altitude
Altitude.

GPS Bearing
True bearing.

GPS Depth
Depth from the sounding transducer to the sea floor. Note that transducers are normally mounted some distance below the water line of a vessel, so that to compute the depth of water we may need to add the distance between the vessel's water line and the transducer to the reported GPS Depth figure. Some depth sounders reporting depth in an NMEA stream have a configuration option which allows adding a fixed distance between the water line and the transducer so that the GPS Depth reported will be the distance from the water line and not from the transducer.

**See Also**

**Working with GPS Receivers**
View - Panes - History

The history pane displays a running history of key actions and results. The history pane persists throughout a session of Manifold, maintaining the history of events even if a new project is opened. Opening or closing a project or saving the active project will log the action into the history pane.

Controls

Freeze - Temporarily disables all output.

Save to File - Save recorded history to a text file.

Copy - Copy recorded history to the Clipboard.

Clear - Clear recorded history.

Print - Print recorded history.

Clearing the contents of the history pane will automatically disable Copy, Print, Save to File and other toolbar buttons working with history text.

Manifold can log information to the history pane such as the time required to execute functions. We can control what information is logged using the Logging options in the Tools - Options dialog.
View - Panes - Info
Reports data attributes of objects in drawings and relevant information for some other components.

Drawings

When a drawing window or a drawing layer in a map has the focus, the info pane shows data from either all objects or only those objects in the selection, showing information for one object at a time. The scope of the info pane is either the set of all objects or the set of selected objects. The context object is the one shown in the info pane.

By default the info pane shows all objects with the context object being the first object. We can step through each object using the First, Next, Previous and Last buttons or by clicking on an object in the drawing to select it.

Center - Center the context object in the window.

Zoom - Center the context object in the window and zoom to fit the object. Zooms are most effective with area or line objects. To distinguish between points, either use Center or Zoom and then zoom in and Ping to see the exact object.

Ping - Highlight the context object by flashing areas and lines and by drawing converging circles about points. Pinging very small lines or areas will also show the location by drawing a series of converging circles. A great way to see what the context object is.

First - Show the first object in the scope as the context object.

Previous - Show the previous object in the scope as the context object.

Next - Show the next object in the scope as the context object.

Last - Show the last object in the scope as the context object.

Filter Selected - Only show selected objects.
**Example**

We import the example drawing of Mexican provinces from the **Examples** folder on the Manifold CD.

We open the drawing and open the info pane using **View - Panes - Info**. We press in the **Filter Selection** button on the info pane toolbar.

Initially, no objects are selected so the info pane shows nothing because there is nothing in the selection.

Using the Query toolbar we select all provinces with a population less than **800000**.

Immediately, the provinces with populations less than **800000** appear in the drawing in red selection color.
The first object in the selection, the province of Baja California Sur, appears in the info pane. If we would like to step through the rest of the selected objects we can press the **Next** button in the toolbar.

Each press of the **Next** button will bring the next object in the selection into the info pane.

To see which of the selected objects is the province of Tlaxcala we can press the **Ping** button to call attention to the Tlaxcala province by flashing the Tlaxcala area object.

Very small areas may be difficult to locate even when they are flashing. We can always press the **Zoom** button to zoom the Tlaxcala province to fit the display window.
This makes it clear where the Tlaxcala object is located. We can zoom out in steps to see the region surrounding it, if desired.

**Profiles and Elevations**

Profiles and elevations are optional components that are available when the Surface Tools package is installed. See the Profiles and Elevations topic for more information.

When the focus is on a profile or elevation window or on a profile layer in a map, the info pane will report the average height for the profile as well as the minimum and maximum height in the profile. The number of decimal digits used after the decimal point is set by opening the elevation or profile and using the View - Display Options dialog to change the number of digits desired for that elevation or profile.
View - Panes - Layers

The **Layers pane** is used with mostly with map windows to control the stack of drawings, images and text components that appear in a map. It is also used with other components, for example, when an image window or drawing window or a layout window has the focus:

- With an image window, the layers pane shows the border, background and image channels so that any of these items may be turned on or off.
- With a drawing window, the layers pane shows the background and also any views of that drawing used in layouts.
- With a print layout window, the layers pane shows individual elements in the layout to enable them to be turned on and off.

**Using the Layers Pane with a Map Window**

The layers pane displays the layer stack in a map. The layers pane is more convenient to use with many layers than the tab controls at the bottom of the map. For intensive image editing work involving many layers it provides faster control over layer characteristics (such as transparency) as well.

**Layers Pane Controls**

- Click on a layer to highlight it and to make it the active layer.
- Use the checkboxes to turn layers on and off for display.
- Each image layer may be set to a percent opacity to specify partial layer opacity.
- Move layers up and down in the layer stack with the **Move Up** and **Move Down** buttons.
- The **Border** and **Background** may be turned off and on using their checkboxes.

- **Switch To** - Make the highlighted layer the active layer in the map. Double clicking on a layer also will make it the active layer.
- **Show All** - Show all layers in the map.
- **Hide All** - Do not show any layers in the map.
- **Move to Top** - Move the active layer to the top of the layer stack.
- **Move Up** - Move the active layer up one position in the layer stack.
- **Move Down** - Move the active layer down one position in the layer stack.
- **Move to Bottom** - Move the active layer to the bottom of the layer stack.
- **Delete Layer** - Remove this layer from the map.
- **Restrictions** - Show and edit layer restrictions for the highlighted layer.
- **Opacity** - Show opacity controls for layers.
- **Properties** - Show properties for this component. Equivalent to opening the component in its own window and choosing View - Properties .

**The Border and Background Layers**
The layers pane will always show two additional layers: the **Border** layer and the **Background** layer. These are system layers and are not real "layers" in that they do not correspond to any drawing or image in the project. Both may be switched ON or OFF via their checkboxes.

The **Background** shows what color to put underneath all other layers. By default white, it may be switched off to easily see if any white space in the map is part of the background or not.

The **Border** shows the proposed size of the image for printing to a printer or to a file. It may also be used as a guide when merging images into each other. The **Border** can be shown in various styles, either as a simple border, as a border with all external areas opaque (to get a better idea of how an image cropped down to the frame size will look), or as a partially transparent matte in regions outside the frame. This latter setting gives an idea of what the final cropped image will look like while still allowing a view of items outside the frame to use as a guide when moving layers about to bring items into view.

### Setting Background Color

Background color for all components is set by default in the Tools - Options dialog. Each individual component can have its background color set by opening the component in a window and choosing View - Properties.

### Layer Restrictions

The **Restrictions** button in the layers pane displays and sets layer restrictions. Layer restrictions may also be set by right clicking on a layer tab in a map window and choosing Restrictions.

Each layer within a map may be specified to be clickable, editable or selectable (in any combination) with mouse commands. Each layer has three restriction options:

- Enable mouse clicks
- Enable mouse editing
- Enable mouse selection

By default, all three options are enabled so objects in layers by default may be clicked, edited or selected.

The layers pane shows edit restrictions with a no marking each restriction. The "yes" implied by default is not shown for greater legibility. For example, in the above illustration the **Cities** layer is clickable but not editable or selectable. Double-click into any restriction setting in the layers pane to toggle it between no and the default yes setting.
If we were to right click on the Cities layer tab in the map and choose Restrictions the Layer Restrictions dialog would show restrictions status for that layer. In this dialog a check mark enables the function and no check mark removes the function. For example unchecking the Enable mouse edits box will prevent a CTRL-ALT click on an object in that layer from selecting it for editing.

Layer restrictions are used to show layers in maps while preventing some layers from participating in mouse commands. This makes it easier to edit desired layers in complex maps. Another use for layer restrictions is in Manifold IMS to restrict the action of hyperlinks or the Info tool to a limited set of layers.

Layer restrictions operate only with mouse commands. Keyboard and menu commands are not limited by layer restrictions. For example, if a layer has had the Enable mouse selection checkbox unchecked none of the mouse selection commands will select objects in that layer. However, using CTRL-A or Edit - Select All will select all objects in that layer, the query toolbar will select objects in that layer and queries will select objects in that layer.

Layer Opacity

Image layers may be given an opacity percentage that applies to the entire layer. Zero percent is no opacity (totally transparent) while one hundred percent opacity makes the layer totally opaque. If an image layer contains an RGBA image where individual pixels may have different degrees of transparency, the layer opacity will be evenly combined in a proportional way with all pixels.

To set layer opacity, press in the Opacity button and an Opacity column will appear in the layers pane. Double-click into the opacity value for each layer to change it. Enter a value from 0 to 100 (no need to enter the % character) and press Enter.

Using the Layers Pane with Drawings

The Layers pane is used to control the appearance of drawings within drawing windows. The layers pane includes checkboxes for the background and border. The border "layer" with drawings shows an enclosing box about the widest extents of objects in the drawing.

By default, drawings are shown using the checkerboard background Manifold uses to provide a backdrop for any transparent regions. The layers pane is shown to the right of the drawing window.
Checking the **Background** box in the layers pane will replace the checkerboard background with whatever is the default background color.

Checking the **Borders** box will draw a one-pixel border that represents the minimum enclosing box for all objects in the drawing. When working with drawings that include points, using the **Border** is a handy way to see if any very small objects exist far away and unnoticed from other objects, since the border will expand to include all objects.

The Layers pane will also show views of the drawing used in print layouts. See the Specifying Views in Layouts topic for details.

**Using the Layers Pane with Images**

The **Layers pane** shows all of the channels in the active image. The appearance of pixels comes from blending primary colors called **channels**. Channels and their use via the Layers pane are described in detail in the Images and Channels topic.

![Layers pane](image)

RGB images consist of three channels: red, green and blue.

By checking or unchecking the channel boxes we can turn each channels ON or OFF for display. For example, checking only the channel for blue and unchecking red and green channels will display a standard RGB image using only the blue tones of which it consists.
RGBa images have an additional channel called the **Alpha** channel that specifies transparency for each pixel.

If we have an RGBa image like the one above,

We can uncheck the Alpha channel.

Doing so removes the influence of the alpha transparency channel and so displays the image as an ordinary RGB image without per-pixel alpha transparency applied.

Compressed images will show R, G and B layers in the layers pane. If channel data from a multi-spectral image has been assigned to the alpha channel for a compressed image using the View - Display Options pane, then an alpha channel layer will appear in the layers pane as well for a compressed image.
See the Images topic and the Images and Channels topic for additional examples using the checkboxes.

**Grayscale and Palette Images**

Both grayscale and palette images have one channel:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Border</td>
<td>Palette</td>
<td>Background</td>
</tr>
</tbody>
</table>

A grayscale image is simply a palette image with a grayscale palette. For both grayscale and palette images the single palette channel will be shown in the Layers pane for these image types.

**Border and Background**

The border and background "layers" appear in the layers pane for images. These checkboxes control the appearance of a border frame around the image as well as the appearance of background color. The screen shots below illustrate the border and background layers pane elements using our sample bronze image. In the examples all pixels other than those in the monument itself have been selected and then deleted so that they are invisible pixels.

The default appearance of invisible pixels is complete transparency, which shows the checkerboard backdrop of all Manifold windows. Without a border it is difficult to see where the image ends.
Checking the **Border** box will turn on a one-pixel wide black border about the edges of the image. This immediately lets us see the horizontal and vertical size of the image.

Checking the **Background** box fills in the image window with background color. This shows us what the image will look like if printed or rendered into a graphics format like .gif or .jpg that does not support alpha transparency.

On a white background it may be difficult to tell where the actual image begins and ends. We can check both **Border** and **Background** to see how the image looks as well as seeing the extent of the image.

**The Layers Pane and Layouts**

When a print layout window has the focus the layers pane will show each item in the layout as a layer. Available commands include:
- Checking a box will turn the layout element on and unchecking the box will turn the layout element off. Hiding an element by unchecking its box will prevent it from being clicked, selected or printed.
- Moving "layers" up and down in the layers pane will move the layout elements up and down relative to each other within the layout.
- Double clicking onto a text label in the layers pane will allow immediate editing of the text in the box directly from the layers pane.
- The **Delete Layer** button in the layers pane toolbar will be enabled when any layer except the main layer is clicked. Deleting a layer will remove this element from the layout.
- The **Properties** button in the layers pane toolbar will open the properties dialog for any component-based element in the layout.

The layers pane is a key control when working with complex layouts.

In the example above we see a layout together with the layers pane. The layout is based on a main element that is a drawing of Europe. Below it is a text element that consist of the phrase "Copyright 2002" repeated several times in an outline font using a light gray color. Above the main element is another text element giving the title, "Europe," and two images, the example **Bronze** and **Schloss** images. The **Background** layer is turned off, so behind the layout page we see the checkerboard pattern used in Manifold when there is no background.

Note that the layout elements added with layout tools, such as text, are shown in the layers pane with special "layout element" icons. Text elements will be named using the initial characters of their text.

With many overlapping elements in a layout we can use the layers pane to turn off upper elements if we want to select or otherwise work with lower elements.

**Layouts in the Layers Pane with other Components**

If a component has any Layouts created they will appear as "layers" in the layers pane for that component. Checking the box for one of these print layout layers will cause a layout rectangle to appear in the component that shows the region covered by the layout.
In the illustration above the drawing has four layouts that show different parts of Mexico. Three of the layouts have been checked in the layers pane causing three layout preview rectangles to appear in the drawing.

The preview layout rectangles will be automatically adjusted if we change the scope of the layout.

For example, suppose we open a drawing window and a layout window for the same drawing and show the layout in the drawing window by checking the layout layer’s checkbox. We select an area in the drawing by clicking on it with Select Touch. The scope of the layout (set by right clicking the layout in the layout window and choosing Properties) is set to entire component.
If we now change the scope of the layout to be the selection, the layout will show only the selected objects (one area, Germany, in this illustration) and simultaneously the drawing window will be updated to show the new region covered by this area.

Right clicking onto the hatched border of one of the layout rectangles in the drawing will cause a context menu to appear with controls based on that layout rectangle. For example, we can Zoom to a given layout rectangle, Print it or change its Properties. If a layout is empty (for example, if the layout scope is set to selection and nothing is selected in the parent component) zooming to the layout will do nothing.

Use Tools - Options - Colors - Layout Rectangle to change the color in which layout rectangles are shown. The default color is black.

Notes

One way of "seeing" invisible pixels is to use the Selections pane built-in invisible pixels selection and to push in the Preview button in the Selections pane to see any invisible pixels in blue preview color. However, invisible pixels are not the only way to render pixels invisible in Manifold images. If the image is an RGBA image it is possible to select some pixels and to set their alpha channel transparency very high so that they are completely transparent. In this case they are not invisible pixels and will not appear in the invisible pixels system selection in the Selections pane.

Only maps can have true "layers" in Manifold in the sense that they can layer more than one component within the same map window. Neither the border and background "layers" in the Layers pane for drawings and images, nor the channel "layers" in the Layers pane for images are true layers even though they appear in the Layers pane in the same manner as do layers in maps. These are simply system controls that take advantage of the Layers pane as a conceptually convenient user interface.

Layers pane settings apply only to the context window, that is the window that has the focus. For example, suppose we have the same RGB image component open in three image windows and also in view in two opened map windows. If we click on one of the image windows to give the focus and turn off the Red channel in the Layers pane, the image will immediately change appearance in the context window but will not change appearance in any of the other opened windows. If we then click on one of the other image windows the Layers pane for that window will still have the Red channel turned on.

View - Panes - Notes

The Notes pane provides a place for making text notes about components and to capture component-specific information. As the focus changes from one component window to the other, the contents of the Notes pane will change to the notes made for that component.

- **Load From File** - Load the contents of a text file into the Notes pane.
- **Save To File** - Save the contents of the Notes pane into a text file.
- **Clear** - Delete all text from the Notes pane.
- **Print** - Print the contents of the Notes pane.

The Notes pane is often left open to a height of a few lines when working with many different component windows. It's then easy to click into the Notes pane and to jot down a few words describing work done, "to do" items for that component and so on. When the project is saved all notes made will be saved as well.

After pasting a drawing or table as a surface when the surface is opened the Notes pane will list the interpolation parameters that were used to create the surface.

The Notes pane will contain EXIF tag information imported for jpg images if the images contain any EXIF tags.
View - Panes - Project

The project pane shows all components in our project. It also shows how components are associated, such as a drawing and its table. We can use the project pane to open components in windows, to drag and drop components into maps, to rename components and to organize components within folders. The status area at the bottom of the pane will provide summary information about any highlighted component.

We can also use the project pane to copy and paste components. Copy and paste within the project pane is used not only to make copies of components, but also to transform one type of component into another. For example, we might copy a geocoded table and paste it as a drawing, or we might copy an image and paste it as a terrain. When using Copy and Paste As to transform one type of component into another, supplemental dialogs will be raised as necessary after the Paste As command.

Click on a component to highlight it. The project pane’s toolbar commands will then apply to that component.

- **Open** - Open the highlighted component in a window. If it is already open, activate the opened window and move it above other open windows.
- **Open in New Window** - Open the highlighted component in a window. If it is already open in a window, open it in a new window.
- **Run** - Run the highlighted component. This command is normally used to run an executable component, such as a script.
- **Cut** - Copy the highlighted component to the Windows clipboard and then delete it from the project.
- **Copy** - Copy the highlighted component to the Windows clipboard.
- **Paste** - Paste the Windows clipboard into the project.
- **Paste As** - Paste the Windows clipboard into the project as a given component. The down arrow pulls down a menu showing what types of components can be used for the data on the clipboard.
- **Delete** - Delete the highlighted component.
Create - Create new components, such as folder, drawings, images, etc. in the project.

Refresh - Appears in Enterprise Edition. Press to refresh the project display immediately in advance of any autorefresh time period, polling all Enterprise servers to see if any shared component has been checked out or checked back in.

CTRL- * - Pressing CTRL- * (Asterisk) with the focus on the Project pane expands all components.

CTRL- / - Pressing CTRL- / (slash) with the focus on the Project pane collapses all components.

Context Menus in the Project Pane

Right clicking on a component will call up a menu of useful commands. For example, the context menu for most components will include an Export command. See the Project Pane - Context Menus topic.

Folders

The create folder button in the project pane toolbar creates folders within the project. Use folders to organize components within the project and to keep the project pane manageable.

This is especially important when importing drawings from complex file formats such as those used with VMAP and TIGER/Line, where a single import will create numerous drawings and maps. Imports will create components within the current folder. Before importing from such formats, create a new folder in the project to highlight it and then choose File - Import. Imported components will be created within the folder specified.

To move files between folders, drag components and drop them into a folder (drop them onto the folder icon itself and not the hierarchy beneath the folder). Folders may be created within other folders. If a folder is highlighted in the project pane and the create folder command is issued, the new folder will be created within the highlighted folder. Folders may be dragged and dropped into other folders. To move a folder out from within another folder, drag it and drop it into the "white space" of the project outside another folder.

Copy and Paste As
View - Panes - Review

The Review pane shows conflicts arising from concurrent multi-user editing of linked drawings, displaying the Manifold object ID of each conflicted object and the conflict, with area, line or point in the Type column indicating an editing conflict. The Review pane works when editing drawings or drawing layers in maps.

To use the Review pane, we must have Enterprise Edition and have also specified a version column in the database table to which the drawing has been linked. In addition, the Edit Mode of the drawing in the Link / Share Status dialog must have been set to Review changes made by others (the default when a version column has been specified). See the Multi-User Editing of Linked Drawings topic for details.

Click on a conflict to highlight it. The Review pane’s toolbar commands will then apply to that component. The drawing window will show the local version of each object conflict in blue and the remote version in red (colors may be set in the Tools - Options dialog). The easiest way to remember the colors is to think that we are always right (of course!) so that changes made by other users are shown in an alarming, red color.

The local version is the object as we have edited it in our project. The remote version is the object as someone else has edited it.

Controls

- **Center** - A “go to” command to center that conflict in the drawing window.
- **Zoom** - Zoom the drawing so that the conflict is completely visible.
- **Use Local** - Commit local changes and update the database to use the local version of the object for the highlighted conflict. Discard changes made by others.
Use All Local - Commit local changes and update the database to use the local version of the object for all conflicts. Discard changes made by others.

Use Remote - Discard local changes and update the database to use the remote version of the object for the highlighted conflict. Download remote changes into the local drawing.

Use All Remote - Discard local changes and update the database to use the remote version of the object for all conflicts. Download remote changes into the local drawing.

View Conflict - Enable (that is, press in, the default setting) to show conflicts in the drawing window using red color and blue color for object geometry and server formatting or local formatting for format conflicts. When not enabled, object conflicts will not be previewed in the drawing window.

(Conflicts pane) A list of editing conflicts and their types detected from editing changes made by other users which conflict with editing changes we make.

Conflict - Either the object ID for editing conflicts involving the metric of objects or the name of the formatting characteristic for a formatting conflict.

Type - Either Area, Line or Point for editing conflicts to indicate the type of object involved or Format to indicate a formatting conflict.

(status bar) A text line at the bottom of the dialog indicating the number of editing conflicts.

Workflow

When presented with a list of conflicts we normally highlight each in turn and then use Center and Zoom to bring each conflict into view in the drawing window. Based on what we see we then decide to use either the local version or the remote version of the object.

If we are feeling particularly authoritative, we can force usage of our edits for all conflicts by choosing the Use All Local command. Conversely, if we think everyone else's edits are to be preferred to ours we can choose the Use All Remote command. Either of these commands should be used with care.

Projects may contain many linked drawings, which could be linked from different data sources. The Review pane will show conflicts for whatever drawing window or drawing layer has the focus.

Reviewing Formatting Conflicts

If the Administrator Console has been used to enable formatting storage on the database server for a linked drawing then linked drawings will show formatting when they are linked into a project and any changes in formatting will be saved back to the database.

Different users can edit the same linked drawing at the same time. If formatting is enabled, different users can change formatting at the same time. Whenever a user changes formatting the new formatting is immediately sent back to the database. Other users working with that same linked drawing will see those formatting changes when they refresh data.

It's a good idea, therefore, to do a Refresh Data command for a linked drawing before changing formatting, to see if someone else has already made any formatting changes not yet displayed. However, even if we do a Refresh Data command it is possible that someone else changes formatting while we are in the process of making formatting changes ourselves and that the other person accomplishes their changes ahead of ours. In that case, an editing conflict will occur. The Review pane will display editing conflicts over formatting and can be used to resolve them.
Selecting an editing conflict with formatting data in the Review pane previews the server version of the formatting in drawing, map and theme windows (the server version of the formatting is applied on top of whatever formatting has been specified locally, to make the difference between formatting as saved on the server and local formatting more noticeable).

**Example**

In this example we consider formatting changes made to the same linked drawing on two different systems. The drawing used is a version of the **US Main** sample drawing that has been exported into an Oracle database. The drawing has had formatting storage enabled through the use of **Administrator Console**. The systems are known as the **Blue** system and the **Green** system, from the color of the different Windows XP color schemes used on the different systems.

On the **Blue** system we open the linked drawing as seen above. The drawing uses a thematic format based upon a **Color** field to color states in the US. California has a pink color because pink color has been assigned in the thematic format for use with the value in the **Color** field associated with California.

On the **Green** system we also open the linked drawing as seen above. Because formatting has been enabled in the Oracle database, whenever we link this drawing into a project it will show the formatting stored with the drawing.
Let's go back to the **Blue** system and change the thematic format.

We will click into the area background color well (the thematic formatting is used for area background color) to launch the thematic formatting dialog. We then click into the pink color well to change the color.

We will change it to a pastel shade of blue-green.
When we press OK in the thematic formatting dialog the drawing will show the new formatting and the change in the thematic format will be automatically uploaded into the database.

It is important for beginners not to get confused over the subtle, but very significant, difference between a thematic format, which specifies formatting, and values of data attributes in a drawing’s table that are used by that thematic format. Changing the color used by a thematic format as seen above is a change in formatting. Changing a data attribute in a drawing’s table is just changing a data attribute, not changing formatting, even though as a result of following the formatting in force it may change the color of a particular object being displayed.

Suppose, for example, that we decided to change the color of the state of California by double-clicking into the drawing onto the California area object to change the value of the Color field for that area. We can see from the screen shots above that pink color had been assigned to a Color value of 1 and gray color had been assigned to a Color value of 3. Had we double-clicked into California and change the Color value from 1 to 3 that would have changed the color used to display the state to gray.

However, that would not have changed the formatting because the thematic format defined for that drawing would still be the same: objects with a Color field of 1 would continue to be drawn in pink and objects with a Color field of 3 would continue to be drawn in gray. It is just that the mix of values for Color for different objects would have changed.

When data attributes in tables are changed for linked drawings those changes are immediately communicated into the database and are not subject to review or resolution as are editing changes in object geometry or in formatting. This is conceptually a difference from the way editing changes in geometry or formatting are handled, but it is the long-standing tradition in multiuser database work to do it that way.

Let's get back to the main theme of this example, the change in formatting done on the Blue system and what effect it has, if any, on the Green system.
Back on the **Green** system, as seen above, we can see that the formatting changes made in the **Blue** system do not appear. They will not appear until we do a **Refresh Data** to synchronize the local display with whatever is already on the server. Suppose we do not do a refresh, but instead go ahead and make formatting changes on the **Green** system?

If we open thematic formatting for area background color on the **Green** system we see that the color well for a **Color** value of 1 is still pink. We click into it to change the color.

Let's change the color to a pastel shade of purple and then click **OK**.
As expected, the color of all areas with a Color value of 1 changes to purple. The Review pane will show a formatting conflict.

We will rearrange our screenshot to show both the Review pane and the drawing window as seen above. Note that the Review pane shows a Format conflict for Area Background. By default, the Review pane shows all conflicts. Until a particular conflict is highlighted, the local display will show local formatting. When we click onto a conflict to highlight the display will show what the version on the server looks like.

When we highlight the conflict the display changes to show the formatting stored on the server, which was set by the user on the Blue system. We can switch back and forth between display of server formatting and local formatting by pressing the View Conflict button to enable or disable it.
With the **View Conflict** button popped out the display will show local formatting. To make a choice between use of server formatting or local formatting we can press one of the **Use** buttons.

For example, pressing the **Use Local** button tells Manifold to resolve the formatting conflict by choosing the local formatting and uploading that into the server to override what was placed there by the user on the **Blue** system.
This resolves the editing conflict by making the server version the same as the local version. The Review pane now no longer shows any editing conflicts.

Note that if we were to now go to the Blue system we would still see the (now obsolete) formatting using pastel blue-green color until we do a Refresh Data command to update the display.

Multi-User Editing of Linked Drawings
View - Properties - Link / Share Status
View - Panes - Selections

The View - Panes - Selections pane is used to save selections for later use. If we select a particular region of pixels in an image, for example, we can save that region so that later, if desired, we can select exactly the same pixels once more. The Selections pane is enabled when the focus is on any component (image, drawing, chart or table) in which selections can be made.

Each component has its own set of saved selections. We can save up to seven selections for each drawing and up to six selections for each image (one saved selection in images is reserved for showing any regions of invisible pixels leaving only six available slots for selections saved by the user). Maps can have as many saved selections as exist within the various drawing and image layers that comprise the map.

When the Selections pane is open, switching focus to a different window will switch the contents of the Selections pane to the saved selections for the component(s) shown in that window. The selections pane will not be enabled if a window from which selections can be made and saved does not have the focus (is the active window or layer).

To Save a Selection

1. Make a selection.
2. Open the Selections pane and press the New Selection button. The selection will be added to the saved selections list as "Selection1"
3. Double click onto the saved selection name to rename it, if desired.

To Use a Saved Selection

1. Click on the target component to make it active. Open the Selections pane.
2. Click on the desired saved selection to highlight it. Checking the Preview box will show that saved selection in blue color in the component so you can see how it relates to any selection currently made.
3. Click on one of the selection command buttons to combine the saved selection with any selection that is currently made. For example, clicking on the Subtract from Selection button will take the highlighted saved selection and will subtract the pixels or objects it contains from the current selection.

To Delete a Saved Selection

1. Click on the desired saved selection to highlight it.
2. Press the Delete Selection button.

Selection Commands

Five selection command buttons are arrayed at the top of the Selections pane. These commands apply to whatever saved selection has been highlighted in the Selections pane. If we click on a saved selection to highlight it and then press one of these buttons, it will be combined with whatever is the current selection in the image. The selection commands allow us to use the saved selection to replace the selection, to add to the selection, to subtract from the selection and to intersect the selection.

Replace Selection - Replace the existing selection with the highlighted saved selection.

Add to Selection - Add the highlighted saved selection to the existing selection.

Subtract from Selection - Subtract the highlighted saved selection from the existing selection.

Invert with Selection - Deselect what is in the highlighted saved selection that was already in the existing selection and otherwise add the highlighted saved selection.
**Intersect Selection** - Select only the region of overlap between the highlighted saved selection and what is in the existing selection. If there is no overlap, nothing will be selected.

**New Selection** - Save the current selection as a new entry in the Selections pane list.

**Delete Selection** - Delete the highlighted saved selection from the Selections pane list.

**Preview** - Press to see a preview (in blue color) in the drawing or image window of the highlighted saved selection.

See the Selection topic for examples.

**Invisible Pixels**

Images in Manifold can have invisible pixels that do not appear in the image. They are simply "placeholders" for empty regions of the image. When images containing invisible pixels are stacked above one another in a map, items in layers below the invisible pixels will be visible.

Invisible pixels are very frequently used when composing advanced images (that is, maps) that consist of stacks of many constituent image components. When working with many different image components that contain transparent regions, especially when combined with images that have white pixels or drawings with "white space" in them, it is easy to forget which parts are transparent and which regions are simply "white space" or white pixels seen through the layer stack.

In addition, we often would like to use the region of invisible pixels in selection combinations with selections made in other parts of the image. To support this usage and to make it easy to always rapidly see the region of invisible pixels, Manifold devotes one of the seven saved selections in images to a saved selection that always shows the region of invisible pixels. This saved selection will appear in the Selections pane if any invisible pixels occur in the image. It cannot be removed from the Selections pane nor can it be renamed.

To see the region of transparency, simply click on this saved selection to highlight it and check the Preview box. It will appear in blue preview color.

See the Invisible Pixels and Selection topic for information on selecting invisible pixels and on using the Invisible Pixels selection in the Selections pane.

**Saved Selections and the Transform Toolbar**

Saved selections will appear in transform toolbar boxes that can work with selection sets. For example, if a drawing has two saved selections called *South West States* and *Mountain West* then these will appear as choices in the transform toolbar when that drawing has the focus.

When drawings appear together in a map, if any drawing layer has the focus the transform toolbar for the map will list all saved selections in all drawings. This is a great convenience, but it also leads to a slight complication in that all saved selections using the same name are treated alike. Saved selections in the same drawing are required to have different names, but saved selections in different drawings might use the same name.

The transform toolbar for the map will treat all drawing saved selections using the same name as one, combined saved selection. For example, if we have two drawing layers in a map, one called *East* and the other called *West* and they both have a saved selection called *Cities*, then using the transform toolbar to create a convex hull using the saved selection choice called *Cities* will use the objects from both the *East* and *West* drawings that appear in their respective *Cities* saved selection.

Therefore, it is a good idea to use unique names for saved selections in drawings that might appear together in the same map. For example, we could name the saved selection in one drawing *East - Cities* and that in the other drawing *West - Cities*. 
See Also

Selection
View - Panes - Tool Properties

Displays settings for the current tool in use, for example, threshold for Select Touch when used with images. The Tool Properties pane is an essential control when editing images with painting tools found on the Tools toolbar.

Tool Properties and Images

When an image window has the focus the Tool Properties pane sets options used with painting and selection tools for images. See, for example, Editing Images.

- **Snap tolerance**: When a snap mode is on, the distance in pixels or physical units within which the cursor must be to a given grid or graticule snap location when snapping to grid or graticule.

- **Value tolerance**: Used with selection, paint bucket fills, etc. Specifies how close a color must be to the color specified before it is considered the same color. Increasing the tolerance value will allow colors that are less and less similar to the touched color to be considered the same.

- **Density**: A technical parameter that defines the relative height of the density curve used for tools that paint pixels using a curve to define the amount of paint applied. Similar in visual effect to the "hardness" tool parameter in PhotoShop.

- **Opacity**: The opacity with which a "Paint" tool is applied. Lower opacity means the tool will not fully cover the pixels it overwrites. Does not apply to tools other than the "Paint" tools, for example, it does not apply to the Brush, Bucket or Gradient tools.

Tool Properties and Tables

When a table window has the focus the Tool Properties pane sets options for use with table operations such as Transform Toolbar operators. Token operations in particular will often use the Separate tokens with setting. Separators are defined in this pane because they are frequently changed during token operations so it is more convenient to have them available in pane that remains open than within an options dialog that is not always visible.

- **Token separators**: Characters to be used to separate tokens. By default the space character, tab, carriage return and newline characters are used as token separators.

- **Week start**: Day that is reckoned to be the beginning of the week. Used in date calculations by Transform toolbar operators such as Copy Day of Week from and similar.

- **Angles**: Units of measure for angular measurements.

- **Number of days in the first week of a year**: The number of days of the year that a week must contain before the year is reckoned to have started with that week. Set to 1 by default, but can be adjusted for different "rounding" of years in calendar calculations. Used in date calculations by the Copy Week from operator in the Transform toolbar.

- **Ignore case**: Treat upper and lower case letters the same in text fields.

- **Ignore leading and trailing whitespace**: Ignore any whitespace characters occurring before or after other characters in text fields. If checked, "Paris" would be considered identical to "Paris".

- **Ignore interior**: Ignore any whitespace distributed within a sequence of
whitespace non-whitespace characters. If checked, "San Luis Obispo" would be considered identical to "SanLuisObispo"

Tool Properties and Surfaces

When a surface window has the focus the Tool Properties pane sets options used with surfaces, namely snap tolerance.

- **Snap tolerance** When a snap mode is on, the distance in pixels or physical units within which the cursor must be to a given grid or graticule snap location when snapping to grid or graticules.

- **Value tolerance** Color tolerance to use to reckon that pixels are the same color as the pixel originally clicked.

Tool Properties and Drawings or Themes

When a drawing or theme window has the focus the Tool Properties pane sets options used with drawings, namely snap tolerance.

- **Snap tolerance** When a snap mode is on, the distance in pixels or physical units within which the cursor must be to a given snap item (such as a line when snapping to lines) before the cursor snaps to that item.

Tool Properties and Drawing Layers in Maps

When a drawing layer in a map is active the tool properties pane is configured to work with the tracing tools. See the Tracing Tools topic.

- **Snap tolerance** When a snap mode is on, the distance in pixels or physical units within which the cursor must be to a given snap item (such as a line when snapping to lines) before the cursor snaps to that item.

- **Value tolerance** Color tolerance to use to reckon that pixels are the same color as the pixel originally clicked.

- **Point size** A distance parameter given in native drawing measurement units that is used to distinguish a point from an area. Pixel regions smaller than this distance will be created as points, while those larger than this distance will be created as areas.

- **Match neighbors** When automatically creating areas, fill in the area to align exactly to the edge of any neighboring areas that already exist.

- **Trim size** A distance parameter given in native drawing measurement units that is used to trim unwanted side lines when automatically creating areas.
View - Panes - Variables

The Variables pane is enabled when the Manifold Debugger is installed.

The Variables pane shows the value of variables within scripts as they are executed together with information about the context in which those variables appear. It may also be used to change the value of variables for debugging purposes. Variables are shown within a hierarchical tree diagram.

- **Show Type** - Press in to show the type of the variable.
- **Show Common Properties** - Press in to show the Application and Parent properties that are common to all Manifold objects. Also controls the display of the Item and _NewEnum properties normally found in collections.

For example, suppose we’ve stopped execution in a script called A at a breakpoint where another script is run.

```java
Sub Main
    Set components = Application.ActiveDocument.ComponentSet
    Set anotherScript = components(components.ItemByName(“B”)).anotherScript.Run
End Sub
```

With both Show buttons pressed in, the Variables pane will report the following values:

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>components</td>
<td>Object</td>
<td></td>
</tr>
<tr>
<td>anotherScript</td>
<td>Object</td>
<td></td>
</tr>
<tr>
<td>Application</td>
<td>Object</td>
<td></td>
</tr>
<tr>
<td>Parent</td>
<td>Object</td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>“B”</td>
<td>String</td>
</tr>
<tr>
<td>Description</td>
<td>“”</td>
<td>String</td>
</tr>
<tr>
<td>ID</td>
<td>2</td>
<td>Long</td>
</tr>
<tr>
<td>Owner</td>
<td>Object</td>
<td></td>
</tr>
</tbody>
</table>

Note that for either of the top hierarchical levels (components or anotherScript) we can expand the hierarchy to see the Application and Parent properties, to expand those properties and so on.

**See Also**

See the Debugger topic for an example of using the Variables pane, including using the Variables pane to change the value of variables during script execution. Other panes used with the debugger include:

- Call Stack
- Watches
View - Panes - ViewBots

**ViewBots** are one-line analytic instruments used to dynamically compute a statistical or comparative measure over a subset of records and are extremely useful for analyzing tables. They are one of the most popular functions in Manifold for experienced users. When a ViewBot is configured for a drawing’s table, it continues to function when the drawing has the focus. For example, if we configure a ViewBot to show the average of a given field for selected items, it will continue reporting the average of the selection whether or not we select items from a drawing’s table or by using mouse selection commands to select objects in the drawing.

Turn on the ViewBots pane with a **SHIFT-ALT-B** ("B" for "ViewBot") or with a View - Panes - ViewBots command.

The ViewBots above, for example, report on those operations they have been told to conduct on the table in view. ViewBots for table windows have many functions.

**To Create a ViewBot**

1. Open the ViewBots pane and press the **New ViewBot** button. A new ViewBot line will be added to the ViewBots pane.
2. Double click onto the saved ViewBot fields to choose analytic functions and the scope of the ViewBot.
3. Press the **Refresh** button to update the results in that ViewBot if the ViewBot autorefresh option is not on in Tools - Options.

**To Make a Selection using a ViewBot**

1. Click on the target component to make it active. Open the ViewBots pane.
2. Click on the desired ViewBot to highlight it.
3. Click on one of the ViewBot pane’s selection command buttons to combine the object set picked out by the ViewBot with any selection that is currently made. For example, clicking on the **Subtract from Selection** button will take the set of objects picked out by the ViewBot and will subtract the objects it contains from the current selection.

**To Delete a ViewBot**

1. Click on the desired saved ViewBot to highlight it.
2. Press the **Delete ViewBot** button.

**To Edit a ViewBot**

1. Double-click on the ViewBot to be edited, or
2. Click on the ViewBot to highlight it and press the **F2** key.

**ViewBots Pane Toolbar Commands**
Use the New ViewBot and Delete ViewBot buttons to create and to remove ViewBots from the pane. Use Refresh and Refresh All to update the calculation in the highlighted ViewBot or in all ViewBots.

Five selection command buttons are arrayed at the top of the ViewBots pane. These commands apply to whatever set of objects is picked out by the highlighted ViewBot. If we click on a ViewBot to highlight it and then press one of these buttons, the object set picked out by that ViewBot will be combined with whatever is the current selection in the image. The selection commands allow us to use object picked out by a View ViewBot to replace the selection, to add to the selection, to subtract from the selection, to invert with the selection and to intersect the selection. For example, if we have a ViewBot that reports the number of objects for which the Elevation is greater than 100, the set of all objects picked out by this ViewBot will be combined with the existing selection with the selection command buttons.

- Move Up - Move the active layer up one position in the layer stack.
- Move Down - Move the active layer down one position in the layer stack.
- Replace Selection - Replace the existing selection with the objects picked out by the highlighted ViewBot.
- Add to Selection - Add the objects picked out by the highlighted ViewBot to the existing selection.
- Subtract from Selection - Subtract the objects picked out by the highlighted ViewBot from the existing selection.
- Invert with Selection - Deselect what is in the objects set picked out by the highlighted ViewBot that was already in the existing selection and otherwise add the ViewBot’s object set.
- Intersect Selection - Select only the region of overlap between the highlighted ViewBot’s objects and what is in the existing selection. If there is no overlap, nothing will be selected.
- Refresh - Update the highlighted ViewBot.
- Refresh All - Update all ViewBots in the pane.
- New ViewBot - Create a new ViewBot line in the ViewBots list.
- Delete ViewBot - Delete the highlighted ViewBot.

Add ViewBot Dialog Controls

- Scope - The objects upon which the ViewBot operates: all objects (or records, pixels, etc), the selection, or the name of any saved selection.
- Column - The name of the field to use. Optional for some operations. For example, Number of Areas or Center X don’t require a field.
- Operation - The ViewBot operator to be employed.
- Argument - Arguments, if required for the operator.
- Ignore Case - Treat upper and lower case letters the same in strings. Used with text operators.
Ignore leading and trailing whitespace

Ignore any space or tab characters in strings. Used with text operators. "This" would be treated the same as "This".

Ignore interior whitespace

Ignore any space or tab characters within strings. Used with text operators. "Th is" would be treated the same as "This".

Caption

String to display for ViewBot results. Can include escape sequences in square brackets:

- [Argument] - Replace with argument in use.
- [Column] - Data field in use.
- [Operation] - Replace with the operation in use.
- [Scope] - Replace with scope in use, such as the name of a saved selection.
- [Scope Size] - Replace with the number of items in the scope.
- [Time] - Estimated time to compute the ViewBot. Normally used when Autorefresh is turned off to warn users of computationally intensive ViewBots that should not be casually refreshed.
- [Value] - Repeats the value computed and displayed in the Value column. Normally redundant.

The default Caption string of [Column] [Operation] [Argument] in [Scope]

creates a reasonably comprehensible sentence for most ViewBots.

Autorefresh viewbot

Command ViewBot to self-refresh on any changes in the subject component. If this value is not checked, a Refresh or Refresh All command in the ViewBots pane will be required to update the value of the ViewBot on any changes.

Selection and ViewBots

Some ViewBots such as the maximum value of a column allow selection from the ViewBot and some (such as the average value of a column) do not.

See Also

See the Selection topic for examples of Replace, Add, Subtract, Invert and Intersect selection command usage.

See the ViewBots topic for examples of ViewBot usage, including use from drawings and use from tables.

ViewBot Operators for lists of operators that may be used within ViewBots.
View - Panes - Views

The Views pane saves specific views into a window at a given location and zoom level under a name. Note that when a component is projected, saving a view at a given zoom level is really saving a view at a specified scale, the scale at which the view is displayed.

We can pan and zoom into a map of Switzerland, for example, so that Geneva is centered in the map and then save that view under the name Geneva. At any time we can jump directly to that view by clicking on the Geneva entry in the Views pane and choosing Apply View.

- **Apply View** - Go to this view.
- **Add New View** - Add the current view to the views pane.
- **Delete** - Delete this view from the views pane.

**To Save a View**

1. Pan and zoom the window to the desired view.
2. Open the views pane if it is not open (use the ALT - SHIFT - V keyboard shortcut if desired).
3. Press the Add New View button to add the view.
4. Click into the view entry to rename it as desired.

**To Go To a View**

1. Open the views pane if it is not open.
2. Click on the view desired to highlight it.
3. Press the Apply View button to go to that view.

If a component for which views have been saved is re-projected, Manifold will attempt to re-compute the extents and location of any defined views into the new projection. However, this will yield reasonably similar views only if the new projection is not too dissimilar to the original projection in which views were defined.

**The Startup View**

By default, the name Startup when given to a view will cause that view to be used whenever the component is opened. In the Tools - Options - User Interface dialog the Save last used view in component, if checked, causes the view called Startup to be used. This option is checked by default. If no view called Startup has been created for that component, then if this option is checked the component will be panned and zoomed to whatever was the last view when the component was last opened.

If the option is not checked, then on opening the component will be zoomed to fit the display window.

For example, if we would like a map to be panned and zoomed to a particular view whenever it is opened, we would open the map, pan and zoom it to the desired view, in the views pane press the Add New View button to add a view and then finally we would click into the new view entry and name that view Startup. Thereafter, whenever the map is opened it will automatically open to that view so long as the Save last used view in component option is checked in the Tools – Option – User Interface dialog.
The **Startup** view also works when programming IMS. Creating an instance of the MapServer object with an empty state string (for example, for the first time in a session for a particular user) automatically goes to the view named **Startup** (case insensitive) if such a view exists.

**Tech Tip**

The views pane works with print layouts windows as well. This is a handy way of navigating complex layouts to zoom in and zoom out onto different features that are frequently used: simply save the desired views in the views pane for quick navigation between views.

The views pane also works with Terrains to save a view of 3D terrain from a given position.
View - Panes - Watches

**Watches** are one-line dynamic instruments that watch and report upon values of variables in scripts or other process parameters. They are used to debug scripts by signaling watched-for conditions.

The **Watches** pane is enabled when the Manifold Debugger is installed.

**Watches** are user-defined expressions that dynamically report on the behavior of a variable or expression. Watch expressions may be a variable, a property, a function call or any valid expression (using arithmetic, for example) within the scripting language in use.

Watches are automatically updated during debugger commands. They will display the value of an expression within a given context and are a great way of monitoring what's going on in the script. In earlier days, one would have to insert short printing statements to print out different expressions as the code executed. In modern times, we can just use a watch to report those values "on the fly" within the Watches pane.

- **New Watch**: Create a new watch. Double-clicking onto the next blank line in the Watches pane is a shortcut for creating a new watch. Double-clicking onto an existing watch is a shortcut for editing it.
- **Delete Watch**: Deletes the highlighted watch from the pane. Highlighting a watch and pressing the **Delete** key will delete it.
- **Show Type**: Press in to show the type of the variable.
- **Show Common Properties**: Press in to show the Application and Parent properties that are common to all Manifold objects. Also controls the display of the **Item** and **_NewEnum** properties normally found in collections.

Double-clicking a watch or highlighting it and pressing the **F2** key will edit its value.

**Example**

Suppose we've stopped execution in a script called **A** at a breakpoint where another script is run.

```vbnet
Sub Main
    Set components = Application.ActiveDocument.ComponentSet
    Set anotherScript = components(components.ItemByName("B"))
    anotherScript.Run
End Sub
```

We've added two new watches to the pane. One watch was created using the expression "**components**" and the other was created using the expression "**components.Count + 1**".

With both **Show** buttons pressed in, the Watches pane will report the following values:
The `components` watch has been expanded. We could further expand the hierarchy to see the `Application` and `Parent` properties, to expand those properties and so on. We can see that the `Count` property for the `components` object has a value of 2.

The `components.Count + 1` expression evaluates to a value of 3.

**See Also**

See the Debugger topic for an example of using the Watches pane. Other panes used with the debugger include:

- Call Stack
- Variables
View - Panes - World

The **World** pane shows the current center point of the active window on a simplified map of the world. In addition, the World pane is used to control Linked Views by specifying **Show Position Reticule** and **Track Position** settings for individual windows. Open the World pane by choosing **View - Panes - World** or by using **SHIFT-ALT-O** to toggle the pane on or off. The World pane may be docked underneath the project pane when using docked panes.

The World pane is context sensitive: it shows the current **Show Position Reticule** and **Track Position** settings for the active window. The World pane announces the active window in the title bar and marks the center point of the active window with a reticule in both the world pane and, if the **Show Position Reticule** option is checked in the active window as well. In the example above, we have opened the **Mexico** sample drawing in a window. The World pane therefore announces **Mexico** as the active drawing and positions the reticule over Mexico in the World pane’s minimap.

![World Pane](image)

**Show Position Reticule** - Show a reticule in this window that always marks the center position of the currently active window (if it falls within the view seen in this window). Push in to activate.

**Track Position** - Pan this window so the center position of the currently active window is centered in this window’s view. Push in to activate.

**(Coordinates Readout)** The bottom of the World pane reports the coordinates of the center point of the active window.

To instruct a window to show a reticule at the current position

1. Open a component in a window.
2. Open the World pane and push in **Show Position Reticule**.

If any other window is now opened (even a second copy of the component opened above) the center point of the current position of the active window will be shown with a reticule.

To instruct a window to track the current position

1. Open a component in a window.
2. Open the World pane and push in **Track Position**.

If any other window is now opened (even a second copy of the component opened above) the tracking component will be panned so that it always shows the current position of the active window centered in view.

See the Linked Views topic for examples.
Properties

View - Properties

The Properties dialog always shows properties for the active window or the active component within a window. The dialog has three main forms depending on the component involved.

Drawings, Images, Labels, Maps and Surfaces

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name of the component. Cannot be changed in this dialog.</td>
</tr>
<tr>
<td>Description</td>
<td>Any text description desired.</td>
</tr>
<tr>
<td>Status info</td>
<td>Shows Local or Linked or Shared.</td>
</tr>
<tr>
<td>Precision</td>
<td>Sets the location precision parameter. See the View - Properties - Precision topic.</td>
</tr>
<tr>
<td>Projection</td>
<td>Projection in use. See Edit - Change Projection and Edit - Assign Projection topics to change the projection. The Properties dialog shortens the name of the coordinate system (projection) in use. To see the full definition of the coordinate system, use the Projection dialog.</td>
</tr>
<tr>
<td>Zooms</td>
<td>Appears for components other than maps. Allows specification of zoom ranges, which are the zoom scales over which the component will appear or disappear when seen in maps. Click the [...] button to the right of the Zooms caption to specify zoom ranges.</td>
</tr>
<tr>
<td>Use custom background color</td>
<td>Background color for all components is set by default in the Tools - Options dialog. Each individual component can have its background color set to a custom color that overrides the system default.</td>
</tr>
</tbody>
</table>

The Link / Share dialog accessed from the [...] browse button for linked or shared components will provide a summary of the link or share properties. This will show the status of a shared component and whether or not changes in a linked component will propagate back to the data source.

Queries

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name of the component. Cannot be changed in this dialog.</td>
</tr>
<tr>
<td>Description</td>
<td>Any text description desired.</td>
</tr>
<tr>
<td>Status info</td>
<td>Shows Local or Shared, with additional status information if Shared showing the Enterprise server involved and whether the component is cached or not cached. Status information other than Local is available only if Enterprise Edition is being used with components linked in from Enterprise servers.</td>
</tr>
<tr>
<td>Use ANSI-compatible Syntax</td>
<td>If checked, specifies usage of ANSI syntax in the SQL query. See the Queries and the SQL in Manifold System topics.</td>
</tr>
</tbody>
</table>
Use cache

If not checked (default), will forcefully re-compute the query each time it is run. Check to caches results of table queries, such as SELECT and TRANSFORM, between invocations. See the Queries topic.

All Other Components

Name
The name of the component. Cannot be changed in this dialog.

Description
Any text description desired.

[Status info]
Shows Local or Shared, with additional status information if Shared showing the Enterprise server involved and whether the component is cached or not cached. Status information other than Local is available only if Enterprise Edition is being used with components linked in from Enterprise servers.

Use custom background color
Background color for all components is set by default in the Tools - Options dialog. Each individual component can have its background color set to a custom color that overrides the system default.

Manifold SQL and ANSI Syntax Option

Manifold’s SQL (used in Queries) is designed to be compatible with Microsoft SQL as implemented in the Microsoft “Jet” database engine. Manifold SQL is intended to be a superset of Jet SQL with features supporting ANSI SQL as well. SQL syntax as documented within the Microsoft Jet SQL Reference for Access 2000 is a practical approach to Manifold SQL.

In addition to being Microsoft-like, Manifold’s SQL engine may be switched into an alternate mode where it parses SQL queries using pure ANSI syntax. To do so, open the query and in the View - Properties dialog check the Use ANSI-compatible syntax box.

When the ANSI option is turned off (the default), line comments start after an apostrophe (’) or double dashes (--) and the names of tables and columns can be enclosed in square brackets ([ ]) or backward apostrophes (‘

strings are enclosed in quotes (“) and times are enclosed in quotes (“) or hashes (#).

When the ANSI option is turned on, line comments start after double dashes (---), the names of tables and columns can be enclosed in square brackets ([ ]) or quotes (“) or backward apostrophes (‘), strings are enclosed in apostrophes (‘) and times are enclosed in apostrophes (‘) or hashes (#).

Clearly, the safest course given that users might change the settings is to use double dashes (---) to mark line comments and to enclose the names of tables and columns in square brackets ([ ]) and to enclose times with hashes (#). The main difference between having the ANSI option off or on is that with it off strings are enclosed in quotes (“) and with the ANSI option on strings are enclosed in apostrophes (‘).
View - Properties - Link / Share Status

The **Link / Share Status** dialog is reached from the **View - Properties** dialog by clicking on the [...] browse button in the **Status** line. This dialog reports on the connection status of linked components as well upon the share status of components shared from Enterprise servers using Enterprise Edition installations of Manifold System. It allows us to alter the **Edit mode** that applies to linked components used to resolve any editing conflicts that arise from concurrent multi-user editing.

**Controls**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linked from</td>
<td>The data source from which the component is linked.</td>
</tr>
<tr>
<td>Using</td>
<td>The connection technology in use.</td>
</tr>
<tr>
<td>Rowset</td>
<td>The rowset within the table, that is, the table or query from which the component is linked.</td>
</tr>
<tr>
<td>(propagation status)</td>
<td>A status line reporting whether or not changes made to the component propagate back to the data source.</td>
</tr>
<tr>
<td>Edit mode</td>
<td>Specifies how editing conflicts arising from multi-user editing of geometry will be handled.</td>
</tr>
<tr>
<td></td>
<td><strong>Overwrite changes made by others</strong> - Do not attempt to detect any changes made to drawing objects by others. Immediately apply any local changes made to drawing objects, overwriting any simultaneous changes made by others. This is the only choice if either a version column has not been specified or if Enterprise edition or above is not used.</td>
</tr>
<tr>
<td></td>
<td><strong>Review changes made by others</strong> - Detect any changes made to drawing objects by others and resolve editing conflicts using the Review pane. This is the default when using Enterprise edition if a version column has been specified.</td>
</tr>
<tr>
<td></td>
<td>The <strong>Edit mode</strong> applies to geometry editing only: as is the case with any table attribute editing, any edits of non-geometry fields in a linked drawing's table will always be immediately applied, overwriting any changes made by another user.</td>
</tr>

- Enterprise Edition
**View - Properties - Precision**

The View - Properties - Precision dialog sets a location precision distance for drawings and maps that defines the radius of action of many commands and operators, including SQL. For example, some drawing transform toolbar operators like Normalize Topology will snap a line end to a point if the line end is closer to the point than the distance given in the Precision dialog. Two points falling within the location precision distance will be deemed coincident. The precision parameter is also important when using automated tools such as Attach and the Topology Factory tool.

This is a critically important parameter that must be understood when using Normalize Topology or other advanced commands. It is necessary because the digital representation of an analog world requires some "quantum" level to determine when a given distance is attained or not attained. For example, if we search for all points within 2 miles of another point, in the digital world there is never exactly a point at the 2 mile distance. It might be at 1.9999999999 miles or 2.0000000001 miles but it won't be "exactly" at 2 miles. The location precision parameter allows us to specify with what precision a distance is truly considered at "2" miles.

The precision parameter is also important for geometric comparisons such as determining if two points are coincident. If they fall within the distance specified by the precision parameter, two locations are considered to be the same.

By default the precision parameter is set to one millionth of whatever measurement unit is used in the drawing's coordinate system. In the case of latitude / longitude drawings this will be one millionth of a degree (about ten centimeters at the Equator). In the case of projected drawings that are meter based, such as the default Orthographic projection, the precision parameter will be one millionth of a meter by default.

Drawings that are imported using less accurate can be "quantized" into a desired precision setting by running Normalize Topology using a new precision setting as follows:

**Quantizing Drawings into a Desired Precision**

1. Open the drawing.
2. Using the tracker tool zoom into the drawing measure the distance between two points that are extremely close to each other but which should be treated as separate locations. These two points ideally should be the very closest that two points should be from each other before they are considered the same.
3. Divide the distance measured above by 10. That is probably a reasonably safe value to use as a sufficiently small precision value that any points closer together than that should be considered the same location.
4. Open the View - Properties - Precision dialog and specify this precision value as the Location Precision value to use. Press OK.
5. Save the .map file.
6. Run Normalize Topology on all objects. This will slightly alter any common area boundaries and other anomalies that have slight overlaps, holes, undershoots, overshoots, etc, within the new Location Precision value so that borders are exactly coincident, overshoots do not occur, points are coincident with the ends of lines, etc.

**Initial Precision Settings**

When we create a drawing, its location precision is set to 0.000001 degrees or 0.000001 meters depending on whether the drawing is in Latitude / Longitude or not. This default value and the default choice of degrees or meters as units of measure stays unchanged unless we modify it by using View - Properties - Precision, or re-project a projected drawing into Latitude / Longitude or vice versa.

**Tech Tips**

The importance of location precision parameter can be seen by importing the mexico_eg sample drawing, opening it, setting location precision to 0.1 and then running Normalize Topology. This achieves, in effect, a "generalize" operation on the drawing that will simplify it (while maintaining topological relationships) to using many fewer coordinates to define the same objects. This is a long computation but well worth the time to see the effect.
Within the Manifold programming and mathematics team the location precision parameter is called the \textit{epsilon}. Some documentation and notes within sample source code may refer to "the epsilon" used for a given action. This is the location precision distance referred to by a more mathematical name.

Because Manifold utilizes double-precision floating point numbers for internal calculations, the ultimate limit of precision with Manifold is approximately one two hundred fifty millionth of a meter at the Equator, accuracy sufficient to "map" the surface of a bacterium or even a virus. This extraordinarily high internal accuracy within Manifold, millions of times more accurate than even survey-grade GIS data, assures users that internal Manifold operations will always preserve whatever accuracy is available within the data set in use. Whatever the data set in use, Manifold’s internal machinery will always be far more accurate.
View - Properties - Zooms

The **Zooms** dialog called from the **View - Properties** dialog for a component has two functions:

- Specifying the zoom ranges over which that component will be displayed when it appears in a map. Zoom ranges only apply when the component is displayed in a map window.
- For vector components (drawings, labels, profiles and themes) specifying the **Render zoom** parameter. The **Render zoom** parameter always applies whenever the component is open either in its own window or within a map window.

Zoom ranges and **Render zoom** values apply only to **projected** components. They have no effect on components that are in Latitude/Longitude unprojected form.

For details on the use of zoom ranges, see the Zoom Ranges topic.

**Controls**

**Minimum Zoom**

The lowest zoom at which the component will be visible in a map window. At zooms lower than this (zoomed further in) the component will not be visible. Leave blank to display at all zooms. Either choose a pre-set value from the pull-down menu or enter a desired custom value.

**Maximum Zoom**

The highest zoom at which the component will be visible in a map window. At zooms higher than this (zoomed further out) the component will not be visible. Leave blank to display at all zooms. Either choose a pre-set value from the pull-down menu or enter a desired custom value.

**Render zoom**

If blank, render labels and point, line and area styles using the **size** parameter in the format toolbar to constantly maintain the same size in printer's points units even if the view is zoomed in or out. If a value is entered, change the size of labels and point, line and area styles to make them larger or smaller in proportion as the view is zoomed in or out. Either choose a pre-set value from the pull-down menu or enter a desired custom value.

**Current Zoom**

The current zoom of the component when the **View - Properties - Zooms** dialog was launched. This provides a reference value from which we may get our bearings when deciding what values for zoom ranges or **Render zoom** we wish to use.

**Render Zoom**

The default operation of Manifold within component and map windows is to provide a "dimensionless" rendering of point, line and area styles so that no matter what zoom is selected the styles will appear using the **size** specified in the format toolbar. For example, if a given point style is specified to be 6 printer's points in size, it will always be shown onscreen exactly 6 points in size. If we zoom in or out the point style will always be shown 6 points in size.

Manifold provides this behavior because vector components such as drawings can be zoomed in or out as much as we like. Normally when, say, many points are clustered together we would like them to continue to be the same size as we zoom further in so that many tightly bunched points can be resolved into visibly separate points.

In the default operation of Manifold, if we wish to have a "paper space" relationship between zooming in and out and the size of symbols such as points, we can use a print layout to create a composition based upon the fixed size of a sheet of paper. When we zoom in and out of a layout, the points and other vector symbols we see will get larger and smaller just as if we were looking at a printed sheet of paper more closely with a magnifying lens or from farther away.

In specialized applications we may want to force component windows to have the same behavior as a print layout display, where the size of labels, points and other symbols will change if we zoom in or out. We can force such
behavior by specifying a **Render zoom** value. The **Render zoom** value specifies the scale at which styles will be drawn exactly at the **size** specified in the format toolbar. Zooming farther in, for lower zoom values, will cause the styles to be drawn proportionately larger in size. Zooming farther out, for higher zoom values, will cause the styles to be drawn proportionately smaller in size.

Inexperienced users are often confused between the free-scale world of vector component windows and map windows and the fixed-scale world of a print layout. The normal way of creating displays in which labels and symbols get larger and smaller as we zoom in or out is to use a **print layout**. Do not use the **Render zoom** parameter as a sloppy way to get a print layout effect within, say, a drawing or a map window just because the use of print layouts or scaling within print layouts is not understood. Better to study the documentation for print layouts and get those concepts clear so that the right tool may be used.

Keep in mind that one of the significant benefits of component windows like drawings and maps is exactly that they do not mimic the behavior of paper maps. For most purposes the default behavior of component windows provides benefits that would be obscured if symbols and labels were to get larger and smaller as we zoomed in. It is natural for beginners to want to approach GIS using the mental paradigms of paper maps, but it would be a mistake if such an approach denied users the signal benefits of a computerized workspace.

On the other hand, there are times when using a **Render zoom** value is the right choice. For example, suppose we want to publish a map component to the web using the Internet Map Server and to keep things conceptually simple for some users we want the resultant images to behave like a print layout when they are viewed. In that case, we can use **Render zoom** to make the image appear like a paper space image so that as visitors zoom farther into the image labels and point styles will appear larger.

**Example**

Consider a map of congressional districts in the US that includes as a layer a drawing containing points for major cities in the US.

We open the map and zoom in to whatever zoom we think will be our “standard” zoom, a typical view.
We then invoke View - Properties - Zooms and note the Current zoom value. It is approximately one to twenty six million.

We can enter 26000000 into the Render zoom box to make this the standard render zoom value.

If we now zoom farther into the drawing the point styles will increase in size. If we zoom twice as far into the drawing the points will be twice as large.

The farther we zoom into the drawing, the larger the point sizes will be, just as if we were viewing a printed sheet of paper through a magnifying lens.

Note that the display computed at the Render zoom value will be the same display, except for increase or decrease in size of symbols and labels, at higher or lower zooms. For example, zooming farther into the map does not allow any overlapping points to be resolved into separate points. This effect can be seen with labels.
Suppose we have a labels layer for the names of major cities in our map and we also set the Render zoom value for that labels layer to 1:26000000 just like the city points layer. Shown above is the map is zoomed to the same starting view, an approximately 1:26000000 zoom. The labels are displayed based upon computations for clipping overlapping labels at that zoom level.

As we zoom farther into the map, the labels simply get larger. No labels are added or deleted.

Just as the case with point styles, the farther we zoom into the map the proportionately larger the labels will become.

Drawing - Color

The Color dialog makes it easy to automatically apply a thematic format to a drawing that colors each adjacent area using a different color.

When applied to a drawing that contains adjacent areas, the Color dialog will add an integer field called Color to the table. (If a field exists that is already named Color the system will create the new field using a name like Color2). The drawing is then examined using Manifold’s internal graph theoretic algorithms to assign a small number to each area in the Color field so that no two adjacent areas have the same value in their Color field.

The Color field is then used in a thematic format to specify both foreground and background color. The colors used are made slightly darker in the foreground color so that the borders of area styles will be distinct.

- **Scope**: [All Objects] by default, but the selection or any saved selection can be used.
- **Save to**: <New Column> is the default, to create a field called Color or similar in naming sequence to which color codes separating adjacent areas by color are written. Existing fields may also be used.
- **Assume areas do not overlap**: Allows a faster spatial computation if checked. If not checked, Manifold will launch an exhaustive computation to resolve possible overlap ambiguities and take much longer.
- **Modify formatting**: If checked (the default) will modify formatting so that adjacent areas are colored differently. If not checked, correct color codes will still be computed and saved to the table. Formatting can then be changed manually, as desired.

**Example**

We've imported a drawing of 2073 census bureau blocks in the San Francisco area. The screen shots below show a detail of the map zoomed into the city of San Francisco itself.

![Map of San Francisco census bureau blocks](image)

Seen default colors the areas are all gray. We would like to color them so that no two adjacent areas share the same color.

To do so, we launch the Color dialog from the Drawing menu. We use the default options with <New Column> in the Save to box and press OK.
After time for processing (there are over 2000 areas in the example) the drawing appears with new colors as seen above. No two adjacent areas share the same color.

The **Color dialog** creates a thematic format for both the **background** color as well as the **foreground** color. The foreground color theme is a darker version of the background color with the expectation that an area style using foreground color for apparent boundary is being used.

<table>
<thead>
<tr>
<th>Area</th>
<th>NAME</th>
<th>Color</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

If we open the drawing's table we can see that a new field, called **Color**, has been added to the table. This field contains the value 0, 1, 2, 3, or 4. The field is then used in the thematic format to color the drawing.

It's easy to change the color scheme after applying the color dialog. Simply click on the color well to be changed for areas and choose **theme** and then apply one of the preset color schemes. The color applied by the color dialog is simply a thematic format using the **Color** field with a **Unique Values** method.
If we apply the Savannah thematic palette preset and then manually change a few colors (by clicking into the color wells and choosing the color we want) we get the results seen above. To create this illustration we changed the foreground color for areas to a dark gray.

If we apply the Greens color preset we get the illustration above. If we don't like any of the color choices in the presets we can double-click into the color wells in the thematic format dialog and change them to whatever we like.

For example, we can double click into one of the color wells assigned by the Greens preset and change it to yellow.
The result will be a change in that color throughout the drawing.

The above examples show alteration of the colors assigned by the color dialog. Using analogous methods in the thematic formatting dialog we could change area styles as well.

**Performance**

Theoretically, one can color a map using no more than four colors. The Color dialog engine will try to use only four colors when reasonably possible. However, the algorithm will use five colors to color the drawing in certain complex area relationships if it determines that solving the four-color problem will take an unreasonably long time. Solving the five-color problem requires much less computation time than finding a solution using only four colors.

The Color dialog works by creating an internal graph-theoretic model of the spatial adjacency relationships between areas. It then applies the Manifold coloring function to find a solution for the coloring of the graph and assigns color codes to areas. Because the algorithm is precise and correctly deals with sophisticated topological issues such as possibly branched areas, computation can be very intensive when many areas are involved. Don't expect to color over 3000 counties in the US in a matter of seconds.

Depending on the speed of the machine involved and the number of areas involved, the Color dialog can take a long time to do its job. Coloring 2073 census block areas in the San Francisco Bay area to create the map used in this example required 21 minutes on a 1 gigahertz Athlon running Windows 2000. On the same machine, the 38 areas representing provinces in our example Mexico map were colored in less than a second.

The census blocks were taken from boundary files downloaded from the Census Bureau's web site. The blocks for all California were imported and then all blocks except those in the area of interest were deleted.
**Drawing - Dissolve**

*Dissolve* is so named because it "dissolves away" or removes the borders between areas that have identical values in data attribute fields. Given a set of areas, it can automatically create new areas that are spatial combinations of areas having the same data attributes. It is available for drawings or drawing layers in maps. Dissolve can also dissolve away the "borders" between lines that are incident to each other. It can also "dissolve" away groups of points to create a centroid for points with a common field value.

Suppose we have a drawing of the US where each state has a region field.

<table>
<thead>
<tr>
<th>Name</th>
<th>Region</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alabama</td>
<td>East</td>
</tr>
<tr>
<td>Arizona</td>
<td>West</td>
</tr>
<tr>
<td>Arkansas</td>
<td>Central</td>
</tr>
<tr>
<td>California</td>
<td>West</td>
</tr>
<tr>
<td>Colorado</td>
<td>West</td>
</tr>
<tr>
<td>Connecticut</td>
<td>East</td>
</tr>
</tbody>
</table>

The value in the region field can be **East**, **West** or **Central**.

If we *Dissolve* all objects in the map using the *Region* field we combine all areas of like region value into one area. Thus, all the states with the value **West** in their *Region* field will be unioned into a single area.

**Dissolve Dialog Controls**

The *Drawing - Dissolve* dialog allows us to choose which areas are to be dissolved, what the guiding field should be and how the field values should be combined.
Dissolve

Dissolve: Choose [All Objects] or the name of a saved selection.

Using: Choose the field to use to guide the dissolve process.

Ignore Case
Combine text strings treating any variation in case as the same string.

Ignore leading and trailing whitespace
Combine text strings without regard to whitespace characters before or after the string.

Ignore internal whitespace
Combine text strings without regard to whitespace characters occurring within the string.

Aggregate Options

(blank) Do not transfer values for this field.

Average Transfer the average value that occurs in this field.

Count Transfer the total number of objects in this field.

Maximum Transfer the maximum value that occurs in this field.

Minimum Transfer the minimum value that occurs in this field.

Sample Randomly choose one of the values from the original object and place it in the combined object.

Sum Transfer the sum of values that occur in this field.

Different aggregate options will be used with different types of information. For example, suppose each state has an Area field that gives the area of the state in square kilometers (or more likely for the US, in square miles…). We would like the Area field for the combined area created by Dissolve to be the Sum of all the areas of the states that were unioned together.

Use with Lines

The classic example of using Dissolve with lines is the case of a drawing showing highways as lines. Quite often in such cases a highway will be composed of many line objects arranged end to end with each line having a data attribute that gives the highway name or number. At times we may wish to create a drawing that has a single line created from all lines that have "5," or "80," or some other number as their highway identifier. We can accomplish this task using Dissolve.
Suppose we have several lines with a **Name** field that contains the value 5 together with two other lines that have the values 18 and 80 in their **Name** fields. The illustration above shows one of the 5 lines selected so it is clear that the longer line sequence at the left of the illustration is composed of more than one line object. The illustration shows the drawing seen in a map with labels created from the lines.

We can run **Drawing - Dissolve** on the drawing using the settings above.

The result is the three line objects that had the same value 5 in their **Name** field have been replaced by a single object that has 5 in its **Name** field. The illustration shows labels drawn aligned to lines so more labels appear for each line object.

**Transfer Rules**

When objects are dissolved into one object, the new object always inherits the value of the field used to guide the dissolve no matter the setting of Transfer Rules for that field. All other fields will be merged together using the settings of transfer rules for those fields.

**Use with Points**

When used with points, Dissolve will find the centroid for all point sharing the same value in the designated field and will replace those points with a single point at the centroid.

Suppose we have a drawing with points. Each point has a field named **Name** with the value 3 or 6. The illustration above shows the drawing in a map with a labels layer above it that shows the value of the **Name** field for each point. The points with a value of 6 have been selected to make it clearer how they are arranged.
As before, we run **Drawing - Dissolve** using the **Name** field.

The result is that all of the "3" points are replaced with a single "3" point at their centroid and all of the "6" points are likewise replaced with a single point.

If we had copied the original drawing we could show it in map with the new points created by Dissolve. The illustration above shows the original drawing with reduced layer opacity so it appears faint and thus the two new points are more clearly visible.

How might Dissolve be used with points in a geographic situation? Drawings imported from some formats, such as VPF (VMAP) or SDTS may at times create drawing layers with points that are intended to be anchor points for labels in the native format. So, for example, we might import a VPF data set that ends up creating a scattering of points, all of which have "Gulf of Mexico" as their value. However, we might wish to have only one point so valued for each different instance of label ("Gulf of Mexico", "Atlantic Ocean," etc.). We can easily accomplish this with Dissolve, which will replace each collection of same-valued points with a single point at their centroid.

**Memory Limitations**

32-bit Windows operating systems cannot allocate more than 2 GB of memory per process. This puts an upper limit on system functioning whereby algorithms that need more than 1 GB of memory (even temporarily) cannot usually operate. For example, using **Dissolve** to dissolve millions of polygons with very large data attributes for each record can exceed the process limit. Research continues at manifold.net to work around this limit of 32-bit Windows systems. As a solution until either 64-bit Windows systems become generally available or until Manifold research finds a way to exceed the limit imposed by 32-bit systems, try running large algorithms in parts.
example, try running a large **Dissolve** on portions of a drawing and then do a **Dissolve** on the results of these runs.
**Drawing - Districts**

The **Drawing - Districts** command assigns areas in the drawing to different districts by writing a district code to a specified data field. Given a drawing that contains areas (usually, adjacent areas like a drawing of the countries of Europe, provinces in a given country, counties in a US state, etc.) the function assign each area to one of the given number of districts such that each district is reasonably compact and contiguous.

If you have acquired the optional Business Tools extension to Manifold System, use of the Districts (Visual) dialog is much preferred to the basic **Districts** dialog.

**Scope**  The set of areas to be assigned to districts.  **[All Objects]** by default, but can be set to the selection or any saved selection.

**Balance**  Field to be used to balance districts.  Districts will be created so each district (as much as possible) has the same total value of this field.

**Save to**  The column to be used to save the district assignment code.  **[New Column]** by default to create a new column called **District**, or a choice of any existing column.

**Threshold**  Areas within this distance will be considered adjacent.  The default value of 0 means that areas touching each other are considered "near" and that areas with no common points are "far" from each other.

**Districts**  The number of districts to which the areas should be assigned.  Choosing 4, for example, will cause each area in the drawing to be assigned to one of four different districts.

**Modify formatting**  Reformat colors of areas so that areas in each district are colored similarly.  Colors used are taken from the same palette used in the Color dialog.

Choosing 4 districts will cause the Districts command to create a new column called **District** and then place a value of 0, 1, 2 or 3 into that column for each area.  All areas with the value 0 will be grouped together next to each other in one district as will the areas with values 1, 2 and 3 respectively.  Redistricting can be accomplished by opening the drawing's table and changing the **District** code for any area that is to be reassigned to different district.

The thematic format created by default will use the **District** column with unique values to specify color.  To change the color scheme used, use thematic formatting to change the colors used to format using the **District** column.

The Districts command is intended to provide simple, initial districting.  For advanced districting allowing greater control and flexibility over the shape and placement of districts, the balancing criteria and other factors, please use the latest **Business Tools** extension for your version of Manifold System.

**Example**

We will create districts using the **mexico_eg** sample drawing (referred to here as "mexico" for brevity).
Seen in default formatting in a drawing window, the *mexico* drawing consists of areas for provinces, each of which has a variety of columns giving geographic and demographic information.

Choose **Drawing - Districts** and choose **SQKM** as the **Balance** field. This field gives the area of each province in square kilometers. Change the number of **Districts** to 4 and press **OK**.

The Districts command will create a new column called **Districts** and will assign each province in *mexico* to one of four different districts by placing the value 0, 1, 2 or 3 into that column for each province. Thematic formatting will then be applied using the **Districts** column as a guide for formatting. The objective of the Districts command is to assign each province into districts so that the sum of the total **SQKM** for each district is the same and so that all areas in each district are contiguous (within the threshold parameter distance). To achieve districts where each district has the same overall **SQKM** total can require some oddly shaped districts although the Districts command will try to keep districts as compact as possible.
We can see that in the case of an irregularly shaped country such as Mexico it is a challenge for the Districts solver to create compact districts that also balance the desired field. In particular, we can select one province that seems it could be swapped for a different province.

Opening the drawing's table we can see that the province of Zacatecas has an area of 73252 square kilometers. It has been assigned to district 2, the brown district. [We used Table - Columns to show only three columns in the table.]

We can click on another province in the green district that seems it could be swapped for Zacatecas.
We see in the table that the province of **Guerrero** has an area of **64281** square kilometers. It has been assigned to district **0**, the green district. Swapping this province for **Zacatecas** would reduce the total square kilometers in the brown district and increase the total square kilometers of the green district, but not by much. We might decide that it is a reasonable trade to keep the provinces more compact.

We can reassign the **Guerrero** province to district **2** by double clicking into the **Districts** cell for the **Guerrero** record and entering the value **2** as seen above. We can then change the **Districts** cell for the **Zacatecas** record to **0** (not illustrated).

We can then click on the drawing, click on the background color well in the formatting toolbar, click on **Thematic** and reapply the formatting to update the formatting of the provinces to using the new values just entered for **District** in the toolbar. The result as seen above is a more compact allocation of provinces into districts.

**Performance**

Districting is easy to do if a drawing fulfills certain limiting conditions, such as a guarantee that areas never overlap and are always perfectly adjacent. Since "real world" drawings often have imperfections, the Manifold districting algorithm uses a **Threshold** factor for determining distance between areas. The algorithm also uses a variety of computational geometry and network algorithms to deal with common imperfections in data sets. As a result, computation with a large number of areas could be slow with a large number of areas and a slow machine. To assess the performance of a particular machine with a given data set, begin by applying Districts to small data sets such as the sample **mexico_eg** drawing and scale up gradually.

Drawing - Minichart

Minicharts are small charts that hover above objects in a drawing. They display the relative values for each object of specified numeric data fields from tables associated with the drawing.

To Create Minicharts in a Drawing

1. Click open a drawing.
2. Choose Drawing - Minichart
3. In the Minichart dialog, use the Add Field button to add numeric fields that are to participate in the minichart.
4. Choose the display Style, Size and Frame color and other parameters. Press OK.

To Remove Minicharts from a Drawing

1. Open the drawing.
2. Choose Drawing - Minichart
3. In the Minicharts dialog click the Select None button to uncheck all fields. Press OK.

Minichart Dialog Controls

- **Select All** - Check all fields in the Chart pane.
- **Select None** - Uncheck all fields in the Chart pane.
- **Select Inverse** - Uncheck all checked fields and check all unchecked fields. A fast way to show all but one field: click Select None, check the one column not desired and then click Select Inverse.
- **Move to Top** - Move highlighted field to the top of the list.
- **Move Up** - Move highlighted field up one position in the list.
- **Move Down** - Move highlighted field down one position in the list.
- **Move to Bottom** - Move highlighted field to the bottom of the list.

**Chart**
A list of columns to chart with colors to use for each. Check a column to display it in the minichart. Double-click into a color well to change the color.

**Style**
Choose from common types of simple charts.

**Frame color**
Color of the border lines used in chart styles.

**Offset point charts by**
When a minichart is created based on data from point objects, specifies the number of printer's points in the X and Y directions to offset it from the point. By default, the offset is 6 points in both X and Y. Increase these values to position the minichart farther away from the point. Offsets must be in the range from -100 to 100 points.

**Size**
Size of the minichart in points.
Resolve overlaps between charts

Checked by default. Do not show minicharts that overlap each other. Uncheck to show all minicharts.

Spacing

Minimum spacing between minicharts in points before minicharts will be hidden to resolve overlaps.

Use with Restraint

Minicharts are visually pretty and fun to use but they are not always effective methods of conveying information about data attributes. The problem is that many small, complex graphical elements sometimes can cause more confusion than enlightenment.

**Drawing - Orthogonalize**

The **Orthogonalize** command moves coordinates to orthogonal grid positions at the specified X and Y grid steps. The command is used mainly to trim insignificant digits from coordinates. For example, suppose we are working with a projected data set expressed in meter-based coordinates and we know that our data set is only accurate within 10 meters. In such cases, there is only an illusion of accuracy when using coordinates such as 34592.490593845 meters. It may as well be 34590 meters. If every coordinate were moved to the nearest ten-meter coordinate position, we would achieve the effect of rounding all coordinates. **Orthogonalize** command performs exactly this function.

Suppose we start with a drawing of Durango province in Mexico using Orthographic projection.

After applying the **Orthogonalize** command with X and Y steps of **25000** meters the province takes on a distinctly stair-step appearance as coordinates are forced to the nearest 25000-meter grid position. The **Orthogonalize** command is not normally used in cases where the original coordinates appear in much finer resolution than the steps specified, so some regions have been collapsed into topologically redundant appendages. These can be fixed by running the Normalize Topology transform toolbar operator.

The **Normalize topology** operator cleans up the topology.
Drawing - Relink / Unlink

The Relink and Unlink commands are enabled when a linked drawing has the focus.

- **Relink** - Used to reconnect a linked drawing to a data source. This command is also available within the drawing's context menu in the project pane. If a linked drawing is disconnected from a data source this command is used to reconnect it. For example, one might create a .map file that contains a linked drawing that is linked to an Access .mdb file. If the .map file and the .mdb file are moved to another machine the link might not continue to work. In that case one can use the Relink command to reconnect the drawing in the project to the .mdb file.

- **Unlink** - Unlink a linked drawing to create a drawing in the project. All data for the drawing is copied from the data source and embedded within the project as would be the case for an ordinary, unlinked drawing.

Linked Drawings
**Drawing - Segmentize**

The *Segmentize* command adds redundant coordinates to objects. It is normally used to make ready for projection very large, simple objects that would otherwise suffer distortion. See the Segmentization topic for discussion of segmentation and projections. The *Segmentize* menu command applies additional coordinates so there is no straight segment of an object that has greater than the given *Distance* between coordinates.

Suppose we have an area that is a simplified rendering of the province of Durango in Mexico, seen in Orthographic projection in a drawing. The province is approximately 440 kilometers wide. The simplified rendition was created by applying Simplify with a *Distance* setting of 25000 meters.

If we click on the area to select it as the primary selected object for editing, edit handles appear at each coordinate that define the area.

Zooming in to the Eastern side of the province we can see that the area consists of straight line segments between the coordinates that define the area.

If we apply *Segmentize* with a *Distance* setting of 10000 meters, Manifold will place redundant coordinates along the straight segments every 10,000 meters. Additional edit handles will appear for each coordinate.

**Tech Tip**
In some circumstances, Segmentize and Simplify are inverse functions. For example, if we applied Simplify again with a setting of 25000 after the Segmentize command shown above the redundant coordinates would be removed.

Segmentization
Simplify
**Drawing - Send Email**
See the Send Email topic.

**See Also**

Business Tools
The **Simplify** command reduces the number of coordinates that define an object. Given a **scope** of action ([All Objects] or a selection) and a **Distance**, the **Simplify** command will reduce the number of coordinates such that the coordinates that define the object are approximately the given distance apart. The **Remove small branches** option will automatically remove branches in multi-branched objects (such as areas with islands or holes) that are smaller than the given distance.

In the example above, the province of Durango from the sample Mexico map has been simplified using **Simplify**. The drawing was first projected into Orthographic projection so that meter-based distances could be used.

The **Simplify** dialog was run with a **Distance** of **25000** meters.

**Comparison to Normalize Topology**

The **Simplify** command is similar to the Normalize Topology transform toolbar operator. However, the **Simplify** command is aimed at simplification on a per-object basis while the **Normalize Topology** operator considers relationships between objects when simplifying them. We can see the difference by running both commands on a drawing of Mexico.

We begin with a drawing of Mexico that's been projected into **Orthographic** projection.
Running **Simplify** with a distance setting of 25000 meters results in the simplification of areas. However, each area is simplified without considering any relationships with adjacent areas. This provides an optimal simplification when each area is considered by itself but also results in overlaps and gaps between areas.

If instead of using **Simplify** we used **Normalize Topology**, we would first use **View - Properties - Precision** to set the **Location Precision** to 25000 meters and then we would run **Normalize Topology**.

**Normalize Topology** takes a lot longer to run than **Simplify**, but the result in the end is free of overlaps and gaps. Each area has been adjusted both on the basis of capturing its own shape as well as to match its neighbors. However, it could be said that the resulting shape for each individual object (without regard to neighboring areas) is not as "optimal" a simplification as is done by **Simplify**.

When simplifying a single object it is probably best to use **Simplify** since the result is obtained much faster. When simplifying many objects for which adjacency must be maintained it is best to use **Normalize Topology**.

**Normalize Topology**

**Segmentize**
**Drawing - Spatial Overlay**

Spatial overlays are a set of methods for transferring data between objects in drawings based on their spatial relationships to each other.

For example, suppose we have a drawing that shows states as areas and we also have a set of points showing the locations of cities. Suppose that each city record has a field called *Population* that gives the population in that city, but that we have no values for the population of each state. We could use spatial overlays to automatically add up the values of the populations for all cities in each state and place that combined value into the *Population* field for each state.

Spatial overlays transfer data from fields in a **Source** object set to a **Target** object set using some **method**. The specific rules used to transfer data are taken from the Transfer Rules specified for each column.

**Spatial Overlay Dialog Controls**

**Source**
Choose an object set to be the source of data. Choices will include the selection, all saved selections, and objects in drawing layers when launched from a map. The source set may contain only objects of one type (that is, all areas, all lines or all points).

**Target**
Choose an object set to receive the transferred data. Choices will include the selection, all saved selections, and objects in drawing layers when launched from a map. The target set may contain only objects of one type (that is, all areas, all lines or all points).

**Method**
Choose a transfer method. Only those operations that make sense for the objects in the source and target sets will be presented. If the source or target set do not contain all objects of one type the method box will not be enabled.

**Spatial Overlay Methods**

The following methods will appear in the **Methods** box as appropriate to the types of objects that have been selected in the **Source** and **Target** sets.

- **Areas to contained areas**
  Transfer fields from area A to areas that are completely inside A.

- **Areas to contained lines**
  Transfer fields from area A to lines that are completely inside A.

- **Areas to contained points**
  Transfer fields from area A to points inside A.

- **Areas to containing areas**
  Transfer fields from area A to areas that completely contain A.

- **Areas to intersecting areas**
  Transfer fields from area A to areas that have at least some location within A’s interior (that is not on a boundary).

- **Areas to intersecting lines**
  Transfer fields from area A to lines that have at least some location within A’s interior (that is not on a boundary). Excludes fully contained lines.

- **Areas to neighbor areas**
  Transfer fields from area A to areas that touch A only at A’s boundary (that is, have no common locations that are interior for A).

- **Areas to neighbor lines**
  Transfer fields from area A to lines that touch A only at A’s boundary.

- **Areas to boundary**
  Transfer fields from area A to points that lie on its
Example

Let’s consider a simple example to see how spatial overlays work.
We've created a drawing with two areas and nine points. Select the points and save them as a saved selection called **Points** in the Selections pane. Select the two areas and save them as a selection called **Areas** in the Selections pane.

<table>
<thead>
<tr>
<th>Population</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>0</td>
</tr>
<tr>
<td>1</td>
</tr>
</tbody>
</table>

The table for this drawing shows that there is one integer field, **Population**. Each of the points has a value of 1 for the population field and is shown with red selection background color in the table. The two areas have values of 0 for the population.

Open the drawing’s table, right click onto the **Population** column and choose **Transfer Rules**.

In the **Transfer Rules** dialog choose **Copy** as the transfer rule for **1 to N** transfers and choose **Sum** as the transfer rule for **N to 1** transfers.

Click onto the drawing window and choose **Drawing - Spatial Overlay**.

In the **Spatial Overlay** dialog choose **Points** as the **Source** and **Areas** as the **Target**. The **Method** will be **Points to containing areas**. Press OK.
The result of the spatial overlays operation is that one area (the triangle) acquires a value of 2 and the other area (the circle) acquires a value of 4. These new values are the sums of the point values within the areas.

Geographic Example

Let's apply the above procedure in a geographic setting. We will sum up the populations of towns to get a total population for each county containing the towns.

We have a drawing called Example that shows counties in the San Francisco Bay area as areas together with points taken from a Census Bureau file of named places with populations.

Opening the Example Table we see that there are ten areas each with a 0 value in the pop1990 field. Numerous towns have populations for each town.

We begin by right clicking on the pop1990 column header in the table and choosing Transfer Rules.
We set the transfer rules for this field to be **Sum** for **N to 1**. Since many points will be combined into each county this is a "many to 1" or **N to 1** transaction. We would like the population values to be summed to get the value for each county.

We don't want any values transferred for the **county** or **Name** fields. We right click onto the **county** column header, choose **Transfer Rules** and choose **None** for the **N to 1** transfer rule. We then right click onto the **Name** column header, choose **Transfer Rules** and once more choose **None** for the **N to 1** transfer rule.

If we were using spatial overlays between different drawing layers in a map we could skip this step; however, since we are transferring values between fields in the same drawing we will use saved selections. Select all points in the drawing and save this selection as a saved selection in the Selections pane called **Places**. Select all points in the drawing and save this selection as a saved selection called **Counties**.

With the focus on the **Examples** drawing window, choose **Drawing - Spatial Overlay**.

In the **Spatial Overlay** dialog choose **Places** for **Source** and **Counties** for **Target**. For the **Method** choose **Points to containing areas** and press **OK**.
In the table we can see that the pop1990 values are filled with the sum of the point values for each county. This is in accordance with the N to 1 transfer rule we specified for this field. Note that there is no change in the county or Name fields for the county areas since we specified None as the transfer rules for these fields.

**Spatial Overlays in Maps**

Spatial overlays may be used in maps when a map contains at least one non-empty drawing. To use spatial overlays between different drawings in a map, the following must be true:

- The same field name and type must be present in both drawings involved.
- Exactly the same set of transfer rules must be used in both drawings for each fields involved.

If the above two conditions are not met for a particular field it will not be transferred at all.

**See Also**

Transfer Rules - Transfer rules specify how fields are aggregated or allotted when new objects are created using transform toolbar operators. Spatial overlays are a different concept than the idea of using transfer rules to aggregate or to allot values when creating objects with transforms. However, it is a related concept in that aggregations or allotments are used to transfer field values between objects.

Transfer Contour Line Height to Points - A simple example using Spatial Overlay.

Shortest Path over Land - A complex example that uses Spatial Overlay.
Drawing - Topology Overlay
See the Topology Overlay topic.
The Transfer Heights command takes heights from a surface and transfers them to objects in drawings (points, lines or areas) that overlay that surface. It is a fast and easy way to get the height of a surface at different points. The Transfer Heights command may be thought of as an analog of the Spatial Overlay command designed for use between surfaces and drawings.

The Drawing - Transfer Heights menu selection is enabled when the optional Surface Tools extension has been installed and the focus is on a drawing window or on a drawing layer in a map window. If you have not activated the Surface Tools extension with a valid Surface Tools serial number you will not be able to use the Drawing - Transfer Heights command.

Launching the Transfer Heights command in the Drawing menu launches the Transfer Heights dialog.

Controls

Source  Choose the surface from which heights will be taken.
Target  Choose the drawing to which heights will be transferred.
[Field] Choose the name of a field in the target drawing's table to which heights will be transferred. If no columns exist in the target table, a choice of [New Column] will create a new column called Height.

Aggregate heights… Specify the method used to assign height values to line and area objects, which extend over many different heights:

Average - Assign the average height found in the line or area.
Maximum - Assign the maximum height found in the line or area.
Minimum - Assign the minimum height found in the line or area.
Sum - Assign the sum of heights found in the line or area.

Example

Suppose we have a drawing of five points showing locations of survey stations in the Montara Mountain region of California. We also have the 1:24K-scale SDTS DEM surface of the region downloaded from the USGS website.
We can show the drawing and the surface together in a map to see where the five points are located relative to the surface.

If we open the drawing’s table we can see that so far there are no fields (except for the default ID field) in the table.

Clicking back on the drawing layer to move the focus there, we can launch the Drawing - Transfer Heights dialog with the above values and then press OK. It doesn't matter what we choose for the Aggregate choice since there are no lines or areas in the drawing.
Instantly, a new field called **Height** will be created in the table and it will be populated with the height of the surface at each point.

**Comments**

Although the above example uses terrain elevation, the **Transfer Heights** command works perfectly well regardless of what data is conveyed by the surface. For example, if we had a surface that showed average temperature the value of average temperature could be transferred as the "height" to objects in the target drawing.

The **Transfer Heights** command is a fast way of noting the height of a surface at points of interest. Simply create a map with the surface and then add a blank drawing layer to the surface. Click with the Insert Point tool to create points where desired and then use **Transfer Heights** to save the height of the surface at each point into the drawing's table.

The **Sum** option for transfer of heights to areas provides a way of aggregating values from surfaces, if those surfaces have been correctly designed for such uses. It locates all the surface's pixels that lie within an overlying area and sums up the value of the height for each pixel.

**Sum** might be used, for example, in a case where a surface represents the concentration of a toxic material deposited downwind of a hazardous material incident (such as an explosion or fire). If the concentration is given in some value per square meter and we know the size of the pixels used to represent the surface, then the **Sum** of values for pixels that occur in a given area will be directly related to the total amount of toxic material deposited within that area. If the area represents, say, a lake or other body of water we can find the total amount of toxic material deposited into that lake.

Note that since clearly, if the same surface is represented with more pixels (that is, each pixel covers a smaller region) then the **Sum** will be greater. However, if we pay attention to the size of pixels in use we can re-scale the result as desired by simply multiplying or dividing the resulting **Sum**.

**See Also**

**Surface Tools**
The **Visible Area** command works with a surface and a drawing to find all parts of the surface that are visible from one or more locations in the drawing marked by points. This function in other GIS systems may be called a *viewshed* function or *visibility zones* function. This function is bi-directional in that it may also be used to find all locations from which the tops of one or more towers are visible from the surface.

The **Drawing - Visible Area** menu selection is enabled when the optional Surface Tools extension has been installed and the focus is on a drawing layer in a map window that also includes a surface layer. If you have not activated the **Surface Tools** extension with a valid **Surface Tools** serial number you will not be able to use the **Drawing - Visible Area** command.

The **Visible Area** command creates a new area object within the target drawing that shows the region of the surface that is visible from the designated points.

Launching the **Visible Area** command in the **Drawing** menu launches the **Visible Area** dialog. The dialog above uses a surface called **Montara Mountain** and a target drawing called **Drawing** (not a very original name, but descriptive).

**Controls**

- **Source**: Choose the surface for which visibility is to be analyzed.
- **Target**: Choose the drawing from which viewing point locations will be taken and within which the visible area will be created.
- **Scope**: [All Objects in drawingname] or the selection or a saved selection, if one exists.
- **Height**: The data field to be used for heights of observing points. Choose [None] if no height field is to be used, in which case the observing points will be taken to lie upon the surface.
  - **Relative Heights**: If unchecked, interpret the height field to mean an absolute altitude. If checked, interpret the height field to mean a relative height above the surface at that location.
  - **Compute area visible from all locations**: If unchecked and multiple points are given the created area will be the region visible from any one of the locations. If checked, the area will represent only that part of the region that is simultaneously visible from all of the locations.

**Using Heights**

If [None] is specified in the **Height** field, Manifold will compute the regions of the surface visible from each location assuming that the observer's eye is located at ground level. That usually is not a realistic choice since a
literally ground level view will easily be obstructed by slight rises that would not impede the view even from the height of an average person's eye.

It is much more frequently the case that we would like to know areas that are visible from a person's eye or from a tower or other structure. In such cases the eye of the observer is elevated to some height above the surface. The **Height** option allows us to specify the name of a column in the drawing's table that provides the heights of each viewing location.

At times the height of the viewing location is known in absolute terms (such as the height of an aircraft observer) and at times the height of the viewing location is known in relative terms (such as the height of a tower above ground level). The **Relative heights** option box allows us to choose which is the case for the height values in our drawing's table. Check this option box to use relative heights, for example, the height of a tower above ground level.

**Example**

This example computes the area visible from five towers in the region of Montara Mountain, California. It uses a drawing of five points and a surface taken from part of the Montara Mountain USGS SDTS DEM data set.

Imported into the project the components appear in the project pane as seen above. The drawing (called **Drawing**) and the surface (called **Montara Mountain**) appear together in a map (called **Map**).

Opening the map we see that the drawing contains five points.
Opening the drawing's table, we see that each point has a **Height** value ranging from 100 to 10. The points have been thematically formatted in the drawing so that the color of each point varies from yellow (the 10 point) to purple (the two 100 points located on ridges).

The drawing represents five towers ranging in height from 10 feet to 100 feet that are located in various parts of the Montara Mountain region.

To find the visible area we click on the drawing tab in the map and launch **Drawing - Visible Area**.

In the **Visible Area** dialog we choose **Montara Mountain** as the **Source**, **Drawing** as the **Target**, [All Objects in Drawing] as the **Scope** and **Height** for the **Height** field. We check the **Relative heights** box because the height for each tower is given as the height above ground level at that position. Press **OK**.
The result is that a new area is added to the drawing. We have taken a moment to format the area in yellow color so that it is easy to see. Any location on the surface within that area is within sight of the top of one of the five towers. Because there are five towers and three of the towers are high towers, much of the surface is visible from at least one of the towers.

Suppose we would like to determine the visible area from only a subset of towers? That’s easy to accomplish.

Let’s suppose we are interested only in the area that is visible from either of the two tallest towers. We delete the new area created in the previous step, and then we select the two tallest towers (the purple dots).
We launch the Visible Areas dialog as before except this time the Scope is set to [Selection in Drawing]. Press OK.

The result is a new area that shows all parts of the surface that are visible from one of the two selected towers. Although it is a smaller area than is visible from all five towers, nonetheless it covers a large part of the surface because the two selected towers are tall towers that are located on high ridges.

So far we have looked at two cases where the visible area is visible from any one of the towers. Suppose we would like to find those regions that are visible from both towers at once?
We could delete the visible area created in the previous step, select the two tall towers and then re-run the Visible Areas dialog. This time we can check the Compute area visible from all locations box.

The result is a new area that shows all parts of the surface visible to both of the two selected towers at the same time. Because line of sight is bi-directional, if we stood at any of the locations marked by the yellow area we would be able to see the tops of both towers.

If we like, we can see which area is visible from all five towers simultaneously.
To do so we launch the **Visible Area** dialog using **[All Objects in Drawing]** for the **Scope** and we check the **Compute area visible from all locations** box.

The result shows that very few locations can be seen from all five towers at the same time. In general, it is only portions of the highest ridges that may be seen from all five towers at once. If we stood at any location within the yellow area we could see all five towers at once.

**Notes**

Only one area object is created by the **Visible Area** command. The area is a branched area object so that even those parts of the area that appear disconnected from other parts of the area all belong to the same area object. Clicking on any one part of the area using touch selection will select the entire area.

Strictly speaking, if we want to consider the visibility of a 100-foot tower we should add some value for the height of the individual who is viewing. One way to do this is to add some average amount, say, 5.5 feet, to the height of each tower.

Line of sight is bi-directional. Every spot that may be seen from the top of a tower is also a spot from which the top of a tower may be seen. The **Visible Area** command not only lets us find all locations that are visible from a given location, it also allows us to find all areas from which the given location is visible. This function is very...
useful in determining whether or not towers or other structures can be seen. For example, if we would like to
determine the areas from which a cellular telephone antenna may be seen we can determine the visible area from
the cellular antenna's location using the height of the antenna. Anyone standing within the visible area will be
able to see the antenna.

This command is very useful for planning any line of sight task. For example, it can be invaluable when planning
the location of monitoring instruments (such as seismic sensors on volcanoes) that connect to central stations via
microwave or laser communications links, the location of observation posts for borders or secure installations or
even the location of defensive positions in military installations.

Computing visible areas can be a highly computationally intensive task that can take a long time to accomplish
with large surfaces or with many viewing points.

Labels Menu

Labels - Text

The Labels - Text menu appears for bound labels components that are created from fields in a parent drawing.
The dialog allows us to change the text strings and fields used to create labels in the component.

The upper pane of the dialog contains fields available in the drawing's table, including intrinsic fields. Double-
click on any of the fields in the upper pane to add it to the text in the lower pane.

See the Creating Labels from Fields topic for information on creating bound labels.
Labels - Synchronized

A labels component is synchronized when it has been created from a drawing with the Automatically label new drawing objects checked on. In that case, whenever a new object is added to the parent drawing a new label will be created for that drawing. Whenever an object is deleted from the parent drawing the label associated with that object will also be deleted. Labels cannot be manually added to or deleted from a synchronized labels component, because the labels in that labels component are automatically created or deleted based upon objects in the parent drawing.

The Labels - Synchronized option toggles labels synchronization on (checkmark) or off (no checkmark). When synchronization is off (no checkmark), then although the labels component is still bound to the parent drawing, labels will not be automatically created or deleted as objects in the parent drawing are created or deleted. This allows us to delete some of the labels, to copy and paste just some of the labels into a new bound labels component and to use the Insert tools to create labels for only some of the objects in the parent drawing. See the Synchronized Labels topic for details and examples.

Editing Labels
Labels
Synchronized Labels
Labels - Unlink

The **Labels - Unlink** command is enabled for labels components that are bound to a parent drawing. A **bound** labels component creates labels based upon objects in a parent drawing and it appears in the project pane hierarchy indented underneath the parent drawing.

If we **unlink** such a labels component we convert the labels within it to ordinary, unbound labels that no longer have any relationship to objects in the parent drawing or to any data attributes for objects in the parent drawing. The current state of whatever text is in those labels based upon fields in the parent drawing (if such are used) will be copied to static text within the labels. The now unbound labels component will move in the project pane hierarchy to the same level as any independent component and will no longer appear indented underneath the parent drawing.

Unlinking a labels component is a "one way" operation. Once unlinked, the labels component cannot thereafter be re-linked to the former parent.

Tools Menu

**Tools - Add-In Manager**

The **Add-In Manager** dialog allows specifying which Manifold System add-ins will be operational for this particular user. In addition, one add-in can be designated to guide the startup configuration of Manifold system.

Add-ins are installed for all users on the computer system. Newly installed add-ins will be enabled for all users. Individual users can open the **Add-In Manager** dialog to specify which add-ins should be loaded for their user name and which add-in will specify toolbar configuration.

The **Add-In Manager** dialog shows a list of all add-ins available in the system with checkboxes next to each. Check the box of an add-in to load it for use when Manifold launches. Uncheck the box to instruct Manifold not to load or use an add-in for this user.

Select All  - Check all add-ins.

Select None  - Uncheck all add-ins.

Select Inverse  - Uncheck all checked add-ins and check all unchecked add-ins. A fast way to use all but one add-in: click **Select None**, check the one add-in not desired and then click **Select Inverse**.

Add-In  This pane lists add-ins available in the system. Check an add-in to make it operational within the system.

Config  Only one add-in can control the startup configuration of toolbars. Double-click into the **Config** column to change the config status of an add-in to **Yes**.

Status Bar  The status bar will show any copyright or comments text embedded into the add-in that is highlighted in the **Add-In** pane. Click on an add-in to highlight it.

After changing settings Manifold System must be exited and then restarted for the new settings to take effect.
See the Add-Ins topic for information on creating add-ins.
Tools - Administrator Console

This topic describes a feature that is provided only within Manifold Database Administrator Edition and is not available in other Manifold System editions. If you have purchased and installed Database Administrator Edition the features described in this topic will be available to you. If you have installed some other Manifold System edition you will not be able to use these features.

The Tools - Administrator Console dialog provides a user interface for DBMS administrators to configure and manage Manifold geospatial data storage within enterprise DBMS data stores. Once database objects are configured with Administrator Console, the enhancements and ease of use features will be available to other users using other Manifold System editions.

Controls

Data Source
The name of the last used data source. Manifold will not actually connect to the last used data source until the Refresh button is pressed. Press the browse button to launch the Data Sources dialog to choose a data source.

(contents pane)
Displays the contents of the data source.

Refresh - Update the contents pane.

Properties - Launch the Properties dialog for the highlighted database object. Allows specification of the friendly name, precision, version column, formatting and server version incrementing options. Also used to configure tables for treatment as drawings with specification of geometry columns and geometry data type.

Triggers - Launch the Triggers dialog for the highlighted database object. View and edit triggers bound to the database object (Oracle only). Shows the trigger, type of trigger and event for each trigger as well as the procedure text.

Run - Press to execute the command line text in the command pane.
Global Filter - Launches a dialog enabling filtering the names of database objects using regular expressions. Changes to the global filter are saved between different sessions of Manifold. By default, the global filter includes several masks suppressing display of system tables commonly found in Oracle databases. See the Tools - Database Console topic for use of the Global Filter button.

Columns - Toggle display of desired columns on or off in the contents pane. Manifold will remember the last used columns between sessions. Data is fetched for columns from the data source on demand.

Columns include:

- **Component** - Show the "friendly" name, that is, the Manifold component name.
- **Format** - Enable storage of formatting for drawings. Double-click into the Format cell of a database object to enable or disable formatting.
- **Precision** - Show location precision used in drawings.
- **Projection** - Projection used by this database object. Double-click into the Projection cell of a database object to launch the database object Projection dialog.
- **Spatial Index** - Reports if a generic spatial index is present for this object. Double-click into the Spatial Index cell of a database object to launch a dialog that enables creating and editing the spatial index. The bounding box of the area covered by the index is editable. A table must have a primary key to allow creation of a spatial index.
- **Statistics** - Useful information, such as the number of objects in drawings or the number of records in tables.

**Caution:** Do not show the Statistics column when database tables may contain very many records. It can take a very long while for some DBMS products to report how many records are in a given table.

- **Triggers** - The number of database triggers, if any, for this object. Double-click into the Triggers cell of a database object to launch the database object Triggers dialog.

Filter

Filter by character sequence - Show only those database objects in the contents pane the name of which contain the given sequence of characters. This is particularly helpful when working with data sources with lots of objects, such as SQL Server or Oracle data sources. See the Tools - Database Console topic for use of the Filter box.

(command pane) A text pane in which command lines, such as SQL, can be entered to be executed by the data source.

(status bar) Information about the highlighted object will be provided at the bottom of the dialog.

### Spatial Index Dialog Controls

The spatial index dialog appears when double-clicking into the Spatial Index cell for a database object that Manifold has been instructed to treat as a drawing.

**Object** - The database object to index. This will be a table name followed by a dot followed by the geometry column to be indexed. A typical name in SQL Server Express, for example, might be `dbo.Mexico Table.GeomI` if we exported a table using the `Geom (I)` intrinsic field to provide a geometry column.
Use spatial index  
Check to create a spatial index.

X and Y boxes  
Four boxes for the X and Y extents to be covered by the spatial index, initially blank until the Suggest button is pressed. The outer two boxes (not editable) show the extents of the data set. The inner two boxes show the extent of the spatial index to be constructed. A spatial index must include all objects in the drawing. Attempting to create a spatial index with bounds that do not include all coordinates of all drawing objects will fail.

Level  
Degree of detail in the spatial index, providing a balance between granularity and performance. Higher values produce more granular indices, which require more space but are potentially more efficient. For best efficiency, choose an index level proportional to the number of objects expected to be in the drawing. The value suggested by the Suggest button is a reasonable default.

Suggest  
Press this button to command Manifold to analyze the data set to determine the extents of the data and a recommended

For details on using the Administrator Console, see the Using Administrator Console topic.

Tech Tip

Keep in mind that the choice of connection technology used in the Data Source will influence how Manifold interacts with the DBMS. For example, ADO .NET connections typically are read-only and will not allow either Administrator Console or Database Console to make changes, such as adding a spatial index, to the database.

Database Administrator Edition
Database Object Projection
Database Object Properties
Database Object Triggers
Spatial DBMS Facilities
Tools - Database Console
Using Administrator Console
Tools - Database Console

The Database Console allows browsing ADO.NET, OLE DB, ODBC or file-based (like .mdb or .xls files) data sources to see what tables are available and what fields and type of fields they contain. Connections may also be made to Oracle databases using the Oracle Call Interface (OCI) for a native Oracle connection, or to spatial DB2 or PostgreSQL databases using a native DB2 or PostgreSQL connection. Toolbar buttons allow importing or linking tables from data sources.

The Database Console is resizable, so we can increase the size of the dialog if we have many objects to display or a lengthy query to write.

The database console understands a variety of spatial DBMS storage methods:

- **Native spatial DBMS** - When using the DBMS's native connection technology to connect to a DBMS providing "built in" spatial capabilities such as Oracle Spatial, IBM DB2 with spatial extender, SQL Server 2008 or PostgreSQL with spatial extensions, database console will automatically utilize the built in spatial features of that DBMS. Images stored as Oracle GeoRasters will also be automatically identified as images.

- **Manifold spatial DBMS** - When connecting to a DBMS used to store spatial information using non-native geometry types supported by Manifold, database console will automatically use Manifold spatial indices and interpret tables containing geometry as drawings. Images and surfaces stored using Manifold facilities will also be automatically identified as images and surfaces. Spatial indices in SQL Server managed by the Manifold Spatial Extender for SQL Server will automatically be recognized and used.

- **ESRI SDE or Personal Geodatabase storages** - If SDE or Personal geodatabase storages are present in the database, database console will recognize those and will configure itself to work with them.

The above are referred to as spatial databases for the purposes of this topic. A spatial database is one of the above three classes of database and is distinguished by having tables that contain geometry for drawings using generic geometry types and generic spatial indices. Although any Manifold edition can read generic spatial DBMS storage enabled with Manifold facilities, only Manifold System Enterprise Edition or greater edition can create such storage.

To work with spatial DBMS using native spatial DBMS capabilities (such as drawings and images stored within Oracle Spatial or Locator facilities within standard Oracle databases), we must have Manifold System Enterprise Edition or greater installed. If we do not have at least Enterprise Edition installed, we will not be able to connect to and use native spatial DBMS capabilities within spatial DBMS products such as IBM DB2 with Spatial Extender, Microsoft SQL Server 2008 (Katmai), Oracle Spatial or PostgreSQL with spatial extensions.

The database console dialog also allows interactive execution from within Manifold of command language statements to manipulate the external database. This allows one to completely control a large data source (such as an Oracle or SQL Server database) from within a Manifold dialog.

**Note:** the example screenshots in this topic use a connection to the Northwind Traders sample Access database that has been set up in the Data Sources dialog. See the examples in the Data Sources Dialog topic.
The database console dialog consists of two panes. The upper, contents pane allows browsing of all tables, fields and queries in the database, including tables in addition to the table that is opened. The bottom pane provides a workspace for writing statements in the command language for that data source (normally SQL/DDL). Database objects in the upper pane are sorted by type (tables are shown together, queries are shown together, etc.) and then by name. Table columns are sorted by name.

Highlighting an item by clicking on it will show what it is. For example, the highlighted table in the illustration above is identified as a TABLE in the small status row at the bottom of the dialog. If the provider supports comments or descriptions for fields, these will appear in tool tips when the mouse hovers over a field. In the illustration above (showing the Nwind.mdb sample database) the description entered into the table design for the Customer ID field is shown as a tool tip when the mouse cursor hovers over that field.

Field types will be shown for any fields highlighted in the contents pane. Field types will be reported using Manifold equivalents so we can see what the column type will be when the table is imported or linked into a Manifold project.

When connecting to a spatial database any tables that contain one or more geometry columns will be shown as drawings in the contents pane. Such drawings may be imported or linked into the project. For example, when connecting to an Oracle database using OCI, any tables that contain one or more SDO_GEOMETRY columns will be shown as drawings in the contents pane. To take another example, when connecting to any database using OLE DB which has a spatial index created by Manifold, any tables that contain one or more geometry columns of
any supported Manifold geometry type (such as OGC Geometry(WKB) or Manifold Geometry) for which a spatial index has been declared will be shown as drawings in the contents pane.

Likewise, images stored either using native DBMS technology or generic Manifold image storage technology will appear with image icons and may be imported or linked into the project. For example, images stored in Oracle databases using GeoRaster technology will appear with image icons. The status readout for an image stored in an Oracle database will show the dimensions of the image, the number of channels and the data type used for image pixels. Surfaces will also appear as images: surfaces may be imported by importing the Height channel of the image.

**Data Source**
The name of the last used data source. Manifold will not actually connect to the last used data source until the Refresh button is pressed. Press the browse button to launch the Data Sources dialog to choose a data source.

**Refresh**
- Update the contents pane.

**Import**
- Imports a copy of the highlighted table into the project. The table will be stored within the Manifold project with no connection to the originating data source. Also used to import drawings from geometry tables in databases or to import images or surfaces from GeoRaster storage in Oracle databases.

**Link**
- Links the highlighted table into the project. The table remains stored in the data source. Also used to link drawings from geometry tables in databases or to link images from GeoRaster storage in Oracle databases.

**Component View**
- Enabled if the Administrator Console has been used to add friendly, component names to this database for database objects. Press in (the default if friendly names are available) to show the database using component names as in a Manifold project. Database objects without friendly names will be hidden.

**Global Filter**
- Launches a dialog enabling filtering the names of database objects using regular expressions. Changes to the global filter are saved between different sessions of Manifold. By default, the global filter includes several masks suppressing display of system tables commonly found in Oracle databases.

**Filter**
- Filter by character sequence - Show only those database objects in the contents pane the name of which contain the given sequence of characters. This is particularly helpful when working with data sources with lots of objects, such as SQL Server or Oracle data sources.

**Run**
- Press to execute the command line text in the command pane.

**Import Query**
- Fetches a copy of the results of the query into the project as a table. The table will be stored within the Manifold project with no connection to the originating data source.

**Link Query**
- Links the results of the query into the project as a table. The data remains stored in the data source.
Note: By default, system tables and views do not appear in the data source contents pane for Access .mdb databases. To cause them to appear, open the Tools - Options - Import and Export dialog and check the option box for Show system tables and views in external data sources.

When connecting via ADO .NET if the database provider supports schemas (introduced in ADO .NET 2.0) then the database console will list tables and columns returned by the database provider.

Friendly Names

Enterprise-class databases used for storing drawings and other data from Manifold will often employ fearsome naming conventions for database objects that, to put it mildly, ordinary users will find threatening. Friendly names, also known as component names, make it possible to use simple, non-threatening, names within the database just like in our Manifold project.

To add friendly names to a database, an administrator must use the Administrator Console to add them. Normally, this is done at the same time a drawing or other Manifold component is first uploaded into a database. If the Administrator Console has not been used to specify friendly names for use in a database, then friendly names will not be available.

When Database Console connects to a data source that has had at least one friendly name assigned with the Administrator Console, Database Console will automatically launch with component view turned on, that is, to display friendly names by default. If for some reason component view has been turned off, we can turn it back on by using the Component View toolbar button. If the data source does not contain a metadata table set up with Administrator Console, the component view button will be disabled.

When using component view, the Database Console dialog will only show components that have been assigned friendly names. The Filter box will work with friendly names as well.

For example, if a drawing is exported into an Oracle Spatial database it might be known within the database as SYSTEM.US_MAINDRAWING.GEOMETRY. In normal usage, of course, everyone would prefer to call that drawing by a simpler name such as US Main.

For example, without friendly names enabled we have to wade through many database objects that are not of interest even if global filtering is set.

With friendly names, when Component View is turned on, we see only those database objects usable as Manifold components as we might in the project view, without any unnecessary clutter.

Note: The Administrator Console is available only in Database Administrator Edition licenses of Manifold System. The ability to enable use of friendly names by the entire organization is one of the many reasons why it makes sense for organizations that use Manifold System to acquire at least one Database Administrator Edition license. Once a Manifold Database Administrator Edition license has been used to create friendly names in a database, then clients using other Manifold licenses, such as Enterprise Edition licenses, can use those friendly names. Therefore, organizations with many Manifold licenses will normally have a few Database
Administrator Edition licenses for their DBMS or IT administrators to use with most of their Manifold licenses being Enterprise Edition licenses.

Resolving Identical Names

If a database object has been assigned the same friendly name then regardless of the Component View setting the Database Console will display the object

Import / Link Options Dialog

Clicking the Import or the Link button will import the highlighted component. If the Administrator Console has been used by a DBMS administrator to pre-configure the import and link options for the component, it will import or link immediately from the database.

Any Manifold edition can connect to a spatial DBMS managed by Manifold using either generic spatial indices or SQL Server running the Manifold Spatial Extender for SQL Server. Enterprise Edition or higher edition is required to export components into such databases, but once the components are uploaded into the database and a spatial index created (for drawings), then any Manifold System edition can import or link that data.

Enterprise Edition is always required to connect to a native spatial DBMS such as DB2 with IBM Spatial Extender, Oracle Locator or Oracle Spatial, PostgreSQL or SQL Server 2008 spatial.

If Administrator Console has not been used to pre-configure import and link options, clicking the Import or the Link button will launch the Import / Link Options dialog to allow specification of options during the import or link process. Most options require spatial DBMS capability, either using a native spatial DBMS or Manifold-managed spatial indices.

<table>
<thead>
<tr>
<th>Name</th>
<th>Name to use for the component that is imported or created.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use all objects</td>
<td>Spatial DBMS only. Import or Link all objects.</td>
</tr>
<tr>
<td>Use all objects in the following area</td>
<td>Spatial DBMS only. Import or link only a subset of objects found within the given X (longitude) and Y (latitude) extents. The read-only X and Y coordinate boxes that surround the editable X and Y coordinate boxes report the minimum and maximum X and Y extents of the data as reported by the data source.</td>
</tr>
<tr>
<td>Require objects to be completely within area</td>
<td>Spatial DBMS only. Enabled if a subset area of interest has been specified. Not checked by default: will import or link any object that has at least one coordinate within the given area of interest. If checked, will import or link only those objects that have all coordinates entirely within the given area of interest.</td>
</tr>
<tr>
<td>Version</td>
<td>Enterprise Edition only. Column to use as the version column for tracking and resolving concurrent multi-user editing conflicts.</td>
</tr>
<tr>
<td>Rely on server to increment version automatically</td>
<td>Spatial DBMS and Enterprise Edition only. Enabled when a Version column is specified. If checked (the default) causes the database (such as Oracle) to increment the version value whenever an object is edited by any user.</td>
</tr>
</tbody>
</table>

Note that some options require Enterprise Edition and others require both use of a spatial DBMS and also Enterprise Edition.

For example, importing or linking a drawing via Database Console will automatically retrieve and use the value for location precision if available. Drawings uploaded as tables into a spatial DBMS from Manifold will store location precision.
Some data sources contain very large numbers of objects such as tables and queries. It is very convenient in such cases to restrict the items shown in the contents pane to only those of interest. We can do so by entering characters matching the desired names into the text box in the toolbar.

For example, if we look at the sample Northwind Traders database without any characters in the text box we see listed in the contents pane everything in the database.

If we enter the character c into the text box we see listed only those objects that have a c in their name. For example, the Suppliers table no longer appears because there is no c in "Suppliers."
If we enter the character sequence `ca` into the text box we see only those objects that have a `c` followed by an `a` in their names.

**Global Filter**

The Global Filter provides a default way of filtering out system level and other DBMS objects we don’t need to see.

Pressing the Global Filter button opens the Filter dialog. The lower pane of the dialog contains a list of masks, which are simply regular expressions using standard regular expression syntax. For example, the `*` asterisk character matches zero or more characters of any type.

Object names that match any of the regular expression masks within the Filter dialog will not be displayed. If we have a mask like `OLAP.*` then any database object that has the letters `OLAP` followed by zero or more characters will match. Such a regular expression matches names like `OLAP1` or `OLAP` or `OLAP.234`. So DBMS names like `OLAP.INDEX` or `OLAPSYS.XML_LOAD_LOG` or similar will not be displayed. See the Regular Expressions topic for details on regular expressions.

To add a new mask, enter the regular expression in the uppermost box in the Filter dialog and press the Add button. To delete a filter, highlight it in the list of filters and press the Delete button. The Add button is enabled whenever text is entered into the upper box, and both the Add and Delete buttons are enabled if any existing mask is highlighted.

**Executing Commands**

The lower pane of the database console allows direct control of databases using the command language (normally SQL or associated languages such as DDL) supported by the provider. For example, when connecting to a SQL Server Express Edition server or to an Oracle Express Edition server, database console is a handy way of creating new tables.

The lower pane of the database console may also be used to execute queries and to import or link the resulting tables into the project. This is an alternate, interactive way of creating tables from queries in addition to creating a Query component.

After creating a query in the lower pane we press Run to execute the query.

**Editing Shortcuts**

The command pane in the lower part of the dialog provides an edit pane into which command statements may be written. For convenience, double clicking a database object in the upper pane will add it to the text in the lower pane at the current cursor position.
For example, suppose we open the database console with the *nwind* sample database and begin writing a query that will use the *Customers* table. We would like to select company names. To do so we double click the *Company Name* field object in the upper pane.

It appears in the lower pane as part of the query. When automatically adding names to a query in this way, Manifold will insert the name of the object into the query using the correct quote characters for the type of database connection being used.
We can continue writing the query by entering `FROM` into the lower pane and then double clicking the `Customers` table object. in the upper pane.

```
SELECT 'Company Name' FROM `Customers`
```

This adds "Customers" to the query text in the lower pane. The ability to add text to the query in the lower pane by double clicking objects in the upper pane is a great way to avoid entering long names manually and also helps avoid typographic errors.

Manifold is reasonably adaptive when loading database object names into the lower pane. For example, double-clicking an image in a spatial DBMS will insert the name of the database table containing the image data.
Using Run makes sense only if the SQL command is an action query used to alter table structures, etc., since there is no way for a SELECT query to report its results within the database console. The SELECT query in the above sequence of editing shortcuts, for example, would have no effect when using Run.

To run a SELECT query like the one above and collect the results in a useful way, press either the Import Query button or the Link Query button so that the results of the query appear as a new table in the project.

For example, if we press the Link Query button with the command text above we will create a linked table in the Manifold project that lists the city and country for each record in the Customers table, as seen below.

After running an action query, press Refresh to update the upper pane in the dialog (necessary if the SQL statement adds or deletes tables or otherwise alters database structure). If a parameterized command is issued in the edit pane the dialog will prompt for values of required input parameters.

The language available within the database console will be whatever language is supported by the underlying OLE DB driver. The execution capability of the database console is therefore driver-specific.

When running SQL within Manifold queries, one is using the Manifold SQL engine. When executing SQL within the database console, one is using whatever SQL is the native SQL of the external database system. One should be aware that SQL implementations in various database systems may contain bugs. If an SQL bug occurs within the database console, the bug should be tracked down with the vendor of the external database system being used.

Examples

Connecting to the Nwind.mdb sample database we could create a new table, alter it and then delete it using the following sequence of commands in the lower pane of the database console, pressing Execute after each command.

```
CREATE TABLE People (Name TEXT, Age NUMBER)

ALTER TABLE People ADD COLUMN Weight NUMBER

DROP TABLE People
```

We can work with other databases through the database console, for example, Microsoft's SQL Server 2000. For examples showing configuration of Microsoft's SQL Server 2000 desktop engine see the SQL Server 2000 desktop engine topic.
Open Data Source Command

Right clicking a component that is linked from an external data source in the Project pane and then choosing **Open Data Source** will open the Database Console and connect to the component data source.

Opening a component linked from an external data source in its own window, and then choosing the **Open Data Source** command in the component menu (for example, choosing **Drawing - Open Data Source** when a linked drawing window is open) does the same thing.

Losing a Connection

Losing a connection to a data source (such as might happen if a network connection to a remote database is interrupted) will disable the object tree in the upper pane as well as the query text lower pane.

Troubleshooting

Sophisticated DBMS installations can very easily be configured with all sorts of security and access permissions that can be difficult to understand. Therefore, if attempting to connect to a database and the connection is not successful, examine very carefully the administrative settings used for the database and connections thereto.

As a confidence-builder in complex situations, it may be helpful to set up a database and connect to it using Manifold to prove to yourself that all is correct with the Manifold installation and with your understanding of Manifold.

For example, install SQL Server Express and connect to it using a data source as given in the Data Sources Dialog topic example.

Note that when specifying a connection in the Data Sources dialog Manifold uses Microsoft configuration dialogs. Manifold uses standard Microsoft technologies, so the key to debugging any connection problems is to understand those standard technologies.

Tech Tip: Connection Methods

Keep in mind that the choice of connection technology will influence how Manifold interacts with the DBMS. For example, ADO .NET connections typically are read-only and will not allow either Administrator Console or Database Console to make changes, such as adding a spatial index, to the database. In another example, to use a spatial DBMS’s native geometry type we must connect to that spatial DBMS using the native connection technology (such as using OCI to connect to Oracle). See the Spatial DBMS Facilities topic for additional information.

Tech Tip: Deletions in Database Console

It’s easy to delete unwanted database tables by writing a drop table query in the query pane at the bottom of the Database Console.

```
drop table SYSTEM.IS_MAIN
```

Simply enter `drop table` and then double-click on the table (drawings and other images are stored as tables in Oracle) in the upper pane to add that name to the query without need to manually enter it. Press the ![run button](run.png) to launch the query and the table will be deleted. Note that the upper list of objects in the database will not be refreshed to show the deletion until we press the Refresh button.
**Tech Tip: Deleting Spatial Components in Database Console**

Using Manifold to store drawings, images or surfaces within a spatial DBMS opens the door to great flexibility, but that flexibility also makes it more complex to delete such components when stored into a spatial DBMS. Storing a component into a DBMS involves storing data in tables within that DBMS and forming metadata relationships with the MFD_META table used by Manifold to keep track of such components. It also makes it possible for other applications or other users to reference the data tables and otherwise form connections to the components in ways that can potentially be very complex.

For that reason, there is no automatic way to delete a component uploaded into a DBMS by just highlighting it and pressing a delete button. Instead, we must follow a simple procedure to delete a drawing, image or surface uploaded into a DBMS:

1. In Database Console, turn off Component View (friendly names) so we can see the full DBMS name of the item to be deleted. Note the name of the object, for example, `dbo.Mexico`.

2. Delete the tables for the component using a DROP TABLE query as given above. This will include the component as well as any spatial index created for it. Hit the Refresh button to see what has been deleted. If an error message such as "Cannot drop the table 'dbo.Mexico', because it does not exist or you do not have permission." pops open, that is a sign that references to that table should be removed from the MFD_META table.

3. Delete all references to that object name within the OBJ field of the MFD_META table. There are two ways to do this:

   a. In Database Console run the following query: `DELETE FROM "MFD_META" WHERE "OBJ"='dbo.Mexico'`

   b. Alternatively: In the Database Console's Filter button, temporarily uncheck the Hide objects matching the following masks box so that all tables are visible, even those we don't normally need to see. Use the Database Console to link the MFD_META table into the Manifold project. This table will appear as a database object with a name like (to use SQL Server as an example) `dbo.MFD_META`. Close the Database Console and use the Query Toolbar or mouse selection to select all records in the table where the OBJ field is equal to the value `dbo.Mexico` and delete those records. After finishing work with this linked table, close it and delete it from the project [deleting it delete the link, not the table itself within the DBMS].

Experienced Manifold DBMS administrators will usually use the second way of eliminating OBJ field references to a deleted table. It's easy to open the MFD_META table in a Manifold project, click on the OBJ column header to sort by the values it contains, and then click once and shift click twice to select all desired values and then press the delete button. This is a quick way of getting rid of similarly-named references to a drawing, the drawing's spatial index and so on. This is quicker and less prone to typographic errors than repeatedly entering a sequence of queries to be executed to delete unwanted records from the MFD_META table.

Tools - Make Image

The Tools - Make Image command (keyboard shortcut F6 key) is used to create images from components. It operates slightly differently depending on whether the component is a print Layout or other component. Layouts are different than ordinary component windows because a layout is directly associated with a specific paper size as printed on a specific printer. Within layouts the key question is what resolution (DPI) should be used for the image since the physical extent of the image is fixed by the page size and the composition in the layout.

On the other hand component windows other than layouts do not have any fixed extent nor are they tied to a specific paper size. Drawings, for example, have limitless extent. When an image is to be created based on a component window there are several different ways in which the extent, scale and resolution of the image can be defined.

When Make Image is launched from a component other than a layout, it allows a choice in the Paint dialog of different ways to output the image based on what is in the display window. When Make Image is launched from a layout, the resolution of the image is specified in DPI.

Controls when used from Layouts

Name
Choose a name to use for the new image. The default name suggested will be constructed from the component name that is displayed in the active window.

Description
Any text entered here will appear in the image's Description property in the View - Properties dialog. Use for whatever user-supplied notes may be desired.

Resolution
Choose the desired image resolution in DPI.

Page
Which page of a multipage layout to capture as an image.

(Status bar)
The status bar region at the bottom of the dialog reports the vertical and horizontal size in pixels and the overall size in megabytes of the image that will be created.

Use Make Image from a layout when an image must be created at a specific DPI. For example, suppose we would like to contribute an illustration to a publication and we have been asked by the publication's art department to provide an image at 600 DPI. Suppose the illustration desired is an image of a map component we have created. We can create a layout using the map and then use Make Image from the layout with a Resolution of 600 DPI. We then open the image and export it to whatever image format file (such as TIFF or JPEG) that is required by the publication.

Controls when used from other Components

Name
Choose a name to use for the new image. The default name suggested will be constructed from the component name that is displayed in the active window.

Description
Any text entered here will appear in the image's Description property in the View - Properties dialog. Use for whatever user-supplied notes may be desired.

Paint
Choose the image output from centered view at current scale, current window, entire component and entire component at current scale.

Size
Horizontal x vertical size of the image to be created in pixels. Enabled when the Paint selection is centered view at current scale or entire component.

(Status bar)
The status bar region at the bottom of the dialog reports the vertical and horizontal size in pixels and the overall size in megabytes of the image that will be created.

Paint Options
**centered view at current scale**

Creates an image at the current scale (zoom level) that shows as much of the image as is possible at the given width and height in pixels. Increasing the size (width and height) will show more of the component in the image.

**current window**

Makes a snapshot of the current window at screen resolution (72 or 96 DPI, typically). The image will reproduce what is seen in the window. This option is very fast.

**entire component**

Creates image at the given width and height in pixels that shows the entire component. Increasing the size of the image by increasing the width and height will still show the entire component, but with greater resolution.

**entire component at current scale**

Creates an image of sufficient height and width to show the component at the current scale (zoom level).

Components like drawings have limitless extent. The "entire component" in this context means the size of the minimum enclosing rectangle that encloses all objects in the drawing. When **entire component** is chosen as the **Paint** option, Manifold will fit the rendering of the drawing to the maximum possible size given the pixel size of the image in width and height.

Use **Make Image** from components other than layouts when an image must be created to a particular scale or of a particular width and height in pixels. For example, suppose we would like to create an image from a highly detailed map that we will use as a wallpaper background image on our Windows desktop. Let's say we have a cool new flat panel monitor with 1900 by 1200 resolution. We can open the map, zoom to about the resolution we would like and then use **Make Image** with the **centered view at current scale** option with width and height set to 1900 by 1200 pixels. We then open the image and export it to the file format we want to use.

Note that to achieve a more detailed, higher resolution view we must use **entire component** with a larger number of pixels. Increasing the number of pixels used with the **centered view at current scale** option does not result in more detail, because the level of resolution is set by whatever scale is being viewed (the "current scale").

**See Also**

See the print Layout topic for layout creation. Layouts are used to print items at desired scales.
Tools - Server Console

The Server Console dialog appears in Manifold System Enterprise Edition. It is used to fetch components from Enterprise servers. Given the name of an Enterprise server data source the Server Console displays all of the components available in that server within a tree diagram. Components may be organized within folders to provide better organization for Enterprise servers that contain many components. Click on a component to highlight it and to enable the toolbar.

Server Choose the name of an ODBC data source to connect to an Enterprise server or specify the connection string. The Server box will show the last used name or connection string. Any PASSWORD and PWD parameters used in a connection string will be masked in the last used name or connection string to protect security.

Refresh - Update the components pane. After choosing a new server one must press the Refresh button.

New Folder - Create a new folder in the tree diagram at the current level. Folders may be nested with folders. To move a component into a folder, drag and drop it into that folder.

Import Component - Fetches a copy of the component into the project as a local component.

Link Component - Links (gets) a component from the Enterprise server into the project as a read-only component. The component remains stored in the Enterprise server.

Delete - Deletes a component from the Enterprise server.

Undo Check Out - Enabled when a component is highlighted that is checked out by the same user in a different project. Such components are shown with a red link icon. Undo Check Out will force such components to be shown as checked in on the Enterprise server. The next time the project in which they are checked out is opened or refreshed the system will automatically perform an Undo Check Out on the components.

(Tree diagram) Displays all components available within this Enterprise server. Components already linked within the project will show a dark gray link icon next to the component icon. Components that are checked out in another project belonging to the current user will be shown in a red link icon.

(Status bar) The status bar region at the bottom of the dialog will report the status of any highlighted component. Components already linked within the current project will be reported as Linked. Components within the Enterprise server but not in use in the current project will be reported as Remote. Components that are checked out in another project belonging to the current user will be reported as Checked out in another project.

Simplified Syntax for SQL Server Connections

Enterprise dialogs allow a simplified connection string syntax for SQL Server databases as an option to full ODBC syntax. \"\systemname\" will connect to the default database on a given system. \"\systemname:database\" connects to the specified database on the given system. The connection established with a simplified connection string that uses Windows integrated security (suitable for users working in Windows Server 2003, Windows XP and Windows 2000). Using simplified connection strings is a fast way to connect to SQL Server or to the SQL Server Database Engine using default options without dealing with the ODBC dialogs.

For example, if we have installed SQL Server on a system called PROJECTS and we have created a database called hydrography to use as our Enterprise server database, we could connect in the Server Console by
entering `projects:hydrography` into the Server box of the Server Console and then pressing the Refresh button.

**Tech Tip:** The Server Console is resizable, so we can increase the size of the dialog if we have many components to display.

**See Also**

**Enterprise Edition**
Tools - Batch Export

This topic describes a feature that is provided only within Manifold Database Administrator Edition and is not available in other Manifold System editions. If you have purchased and installed Database Administrator Edition, the features described in this topic will be available to you. If you have installed some other Manifold System edition you will not be able to use these features.

The Tools - Batch Export command works with Oracle databases only. It allows users of Database Administrator Edition to export many drawings, images, and surfaces at once into an Oracle database. The Oracle server must support SDO_GEOMETRY for upload of drawings, and it must support GeoRasters for upload of images and surfaces.

The Batch Export dialog combines the functions of File - Export dialogs for drawings, images, and surfaces into a single dialog, using similar controls. The Batch Export dialog is resizeable.

Control Panel

The Batch Export dialog contains the following controls:

### Server

The name of the Oracle server. oracledb is the default if the full enterprise Oracle product was installed using the directions in the Installing Oracle topic. In the case of Oracle Express installations the server name is xe by default. See the directions for connection in the Installing Oracle topic.

### User Name

An authorized user name to login onto the Oracle server. system is the default system administrator name if the server was installed using the directions in the Installing Oracle topic. Experienced Oracle IT managers will provide users with their own login names.
**Password**  
Password to use to login to the Oracle server.

**Connect**  
Press this button to connect to the Oracle server and to enable dialog controls. Some other controls, such as the OK button, will not be enabled until a connection has been established.

**Select All** - Check all components.

**Select None** - Uncheck all components. No components will be exported. Tech tip: Use this to uncheck all components before checking those desired.

**Select Inverse** - Uncheck all previously checked components and check all previously unchecked components. This is a fast way to check only a few components out of many: uncheck those desired and then push **Select Inverse**.

**Component pane**  
A list of components in the project available for export. Checking the box of a component will export it. Some controls in the dialog will not be enabled unless a component of that type has been checked. Most column values are editable. To edit a specific column value, double-click it. Columns in the pane include:

- **Component** - The name of the component in the Manifold project.
- **Export As** - Name to use for this component in the database. Friendly names may be specified in this column.
- **Precision** - Location precision parameter to be used for drawings. Expressed in whatever native drawing units are used by that drawing.
- **Projection** - Coordinate system to be used within Oracle for this component. Manifold will use the same projection used by the drawing if it is supported by the server (nearly always possible) or whichever is the most similar projection available on the server. Double-click to launch the **Projection** dialog that allows choosing an Oracle projection. Using a projection on the server different than that used by the drawing will require re-projecting the drawing, which can take a significant amount of time for large drawings.

### Drawings

<table>
<thead>
<tr>
<th>Identity column</th>
<th>Allows customizing the name of the identity column. <strong>OID</strong> by default.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Geometry column</td>
<td>Allows customizing the name of the geometry column. <strong>Geometry</strong> by default.</td>
</tr>
<tr>
<td>Version column</td>
<td>Allows customizing the name of the version column. <strong>Version</strong> by default.</td>
</tr>
<tr>
<td>Do not reproject data</td>
<td>Off by default. Check to prevent re-projection of data on export, as might be required to match the projection in use by Manifold to an available Oracle projection.</td>
</tr>
<tr>
<td>Create spatial index</td>
<td>Checked by default. Creates an Oracle spatial index for the table containing the drawing, which makes certain Oracle spatial operations faster.</td>
</tr>
<tr>
<td>Create sequence and triggers</td>
<td>Checked by default. Creates a sequence object to generate values for the ID column, a trigger to fill values in the ID column for newly inserted records, and another trigger to update values in the Version column for</td>
</tr>
</tbody>
</table>
changed records.

**Images and surfaces**

- **Do not reproject data**
  Off by default. Check to prevent re-projection of data on export, as might be required to match the projection in use by Manifold to an available Oracle projection.

- **Create pyramids**
  Create intermediate level images to enable much faster zooming and panning. Always leave this checked unless you are a maximum Oracle GeoRaster expert and have some specialized reason not to create pyramids.

- **Split data into tiles**
  Off by default. If checked, will split image data into tiles of the specified size instead of sending image data in one chunk. For use by Oracle experts who wish to tune image storage in the DBMS.

- **Preserve image library tile structure**
  On by default and used when exporting an image library image to Oracle. When on, the export process will create a separate database tile for each file in the image library, scaling pixels as necessary. When off, the export will send the image library as an ordinary image component and will cut pixels into new tiles if need be.

The default name of the identity column used when exporting a drawing to an Oracle database is **OID** to avoid naming collisions with the **ID** column that stores Manifold object IDs in Manifold drawings.

When we press the **OK** button to tell the **Batch Export** dialog to go to work exporting components that have been checked in the components pane, as each component is exported the box for it will be automatically unchecked. This facilitates canceling the **Batch Export** process, which can be lengthy in the case of many components or large components and then restarting the **Batch Export** process at a more convenient time with only the remaining components checked.

Tools - Customize

The Customize dialog adds and removes panes and toolbars from the main Manifold display. Check the box to show the associated pane or toolbar.

Toolbars will automatically become enabled or disabled for usage as different windows become active. For example, the Format toolbar will be active when we click into a drawing window or into a map window for a map that includes drawings, but it will be inactive when we click into an image window [formatting applies only to drawings].

Therefore, to list a toolbar in the Customize dialog so that it may be checked on or off, first open a window that would normally use that toolbar. It will then be listed in the Customize dialog.
Tools - Options

The **Tools - Options** dialog allows setting of user preferences. Click on an options category in the left-hand pane and settable options for that category will appear in the right-hand pane.

Some options (such as the Location value for File Locations) may be set by double clicking into the option field, entering text, and then pressing **Enter**.

**Automatic Updates**

Configures Manifold to check for updates when it starts up. On by default, with a check every seven days. This option functions only when Manifold is launched interactively. It does not apply to runtime editions, nor does it function if Manifold is launched programmatically, such as within an IMS application.

- **Check for updates automatically**
  - When Manifold starts up, connect via Internet to the Manifold update server and see if an update has been published for the currently running version. On by default.

- **Check every time the application starts**
  - Check for updates every time Manifold is launched interactively.

- **Check every [ ] day(s)**
  - Check only every given number of days, seven by default.

When this function runs, upon startup Manifold will connect to the **manifold.net** update server, check to see if there have been any updates issued for the currently running version of Manifold and, if so, will pop open a message inviting the operator to visit the update site.

No information is ever transmitted to the update server and no data except information on published updates is ever downloaded from the update server.

This command requires Internet access for Manifold using ordinary HTTP protocol, the same as used by web browsers like Internet Explorer. If the computer is not connected to Internet or if HTTP is blocked by a firewall or other security mechanism, this command cannot work. In general, if you can launch a web browser and visit web sites from your computer this command will work.

**Colors**

Specify default colors for formats and user interface items.

**Color Palettes**

Lists color palettes available within the system. Palettes are used for thematic formatting and to color surfaces and terrains. See Customization for information on adding new palettes.

**Confirmations**

Specify which confirmation dialogs will pop up on given actions. Most delete operations, for example, will require a confirmation by default.

- **Confirm bulk operations on editing conflicts**
  - Used with multi-user editing operations. Turns on confirmations for the **Use All Local** and **Use All Remote** toolbar buttons in the Review pane on and off.

- **Confirm closing project containing checked out components**
  - Used with **Enterprise Edition**. Raise a confirmation dialog if a project contains components checked out for editing from the Enterprise server. Until such a component is checked in no one else can check out the component for editing.
Confirm creating undo actions larger than...

Never create undo actions larger than...

Undo functionality for large images and surfaces requires creation of potentially very large temporary files on hard disk. These two settings allow setting limits on what size actions can be undone. The larger the sizes specified the slower the system will perform due to the overhead of making ready for an Undo, if commanded. See the Edit - Undo / Redo topic for more information.

Confirm deleting components

Raise a confirmation dialog before deleting a component.

Confirm deleting drawing objects

Raise a confirmation dialog before deleting an object in a drawing.

Confirm deleting image pixels

Raise a confirmation dialog before deleting pixels in an image.

Confirm deleting labels

Raise a confirmation dialog before deleting labels in a labels component.

Confirm deleting layout objects

Raise a confirmation dialog before deleting an element in a layout.

Confirm deleting table columns

Raise a confirmation dialog before deleting a column (field) from a table.

Confirm deleting table records

Raise a confirmation dialog before deleting a record (row) in a table.

Confirm expanding images or surfaces when pasting

When pasting pixels into an image or surface the image or surface rectangle may need to be increased to house both the original pixels and the new pixels. Confirm before doing so. This confirmation is an important step in case what were thought to be identically georegistered images are in fact located far from each other and thus would result in an immensely large image.

Confirm executing action queries

Raise a confirmation dialog before running an action query.

Confirm exiting application

Raise a confirmation dialog before closing Manifold System.

Confirm modifying table structure

Raise a confirmation dialog before modifying the structure of a table, such as through the Design dialog.

Confirm projecting data

Raise a confirmation dialog before re-projecting data. On by default.

Confirm re-assigning projection after projecting data

Checked by default to warn against the almost always inappropriate use of Assign Projection after Change Projection has been used. Un-checking this option is almost certainly a mistake except for experts in rare and unusual circumstances. See the Inadvertent Usage section in the Edit - Assign Projection topic.

File Locations

Locations to be used by default for files can be specified in File Locations. Locations that may be specified include:

Configuration

The location of customization files.

Also, running a .NET script first searches for referenced assemblies that use relative paths in the Manifold installation folder and then searches...
in the Configuration folder

**Data Cache**
Location of cached files used when linking images from OGC WMS image servers and TerraServer and other image servers when the Cache data between sessions option is turned ON (the default). The default value for the location is `%MyDocuments%`. See the Linked Images from OGC WMS Servers topic, the Linked Images from TerraServer topic and the Managing Cache Files topic.

**Datum Grids**
The location of .gsb and their accompanying .xml files used to specify custom datum grids for NTv2 transformations. By default, contains the value `%Manifold%\Grids` to use a Grids folder within the main Manifold installation folder. See the Custom Datum Grids for NTv2 topic.

**Geocoding Database**
The location of the Manifold Geocoding Data product to use for street address geocoding. See the Street Address Geocoding topic.

**Geocoding Extensions**
Location of the file used for user extensions to the street address geocoding database. See the Street Address Geocoding topic.

**Import and Export**
The location of files used for import and export. Normally specified as a dot, the current folder.

**MrSID Decode Utility**
The name of the auxiliary program used to decode MrSID files into standard GIS format, which must be in the Windows PATH for executable files. By default, `mrsiddecode.exe`. See the Import Image - SID, MrSID topic for details.

**MrSID Info Utility**
The name of the auxiliary program used to provide information on MrSID files, which must be in the Windows PATH for executable files. By default, `mrsidinfo.exe`. See the Import Image - SID, MrSID topic for details.

**Projects**
The default location to use for opening and saving projects.

**Web Pages**
Location to which web sites created with the File - Export - Web Page command should be saved. By default, `C:\Inetpub\Wwwroot`. See the Map Server Overview topic.

In addition to literal settings such as "c:\storage\gisfiles" file locations can be specified using escape sequences as follows:

- `%CommonDesktop%` Desktop shared by all users
- `%CommonDocuments%` Folder for documents shared by all users
- `%Desktop%` User-specific desktop
- `%MyDocuments%` User-specific folder for generic documents
- `%MyMusic%` User-specific folder for music files
- `%MyPictures%` User-specific folder for image files
- `%Manifold%` Manifold installation folder
- `. (dot) Current folder.
For example,

<table>
<thead>
<tr>
<th>Name</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>Projects</td>
<td>%MyDocuments%</td>
</tr>
<tr>
<td>Import and Export</td>
<td></td>
</tr>
</tbody>
</table>

...will open the My Documents folder whenever a project is saved or loaded. Import and export will occur in whatever folder was last active.

The above setting assumes we have created a folder called Manifold Projects in the My Documents folder for this user. Opening or saving any project will occur by default within the Manifold Projects folder.

Escape sequences are case-sensitive. %MyDocuments% is not the same as %mydocuments%.

Caution: Cache files persist forever and, in extreme cases, use up your free disk space unless they are manually deleted. See the recommended actions in the Managing Cache Files topic.

Fonts

Default fonts used by various system elements. Fonts used with script windows will be restricted to fixed-width fonts.

Geocoding

Use default country
Set the country to be used if the table does not contain any explicit country field. By default, the United States. Not significant unless MapPoint is being used to geocode addresses outside of the United States. Note: although not all countries listed in the combo box are supported by MapPoint, the list of countries is taken from the Microsoft MapPoint programmatic interface for compatibility with any future extensions that may be offered. This option may be turned off to aid geocoding with both MapPoint North America and MapPoint Europe at the same time.

Use Manifold Geocoding Database
Enabled if the Manifold Geocoding Data product has been installed. Check this box to use the geocoding database (for US street address geocoding). Will be disabled if the Manifold Geocoding Data product is not installed.

Use MapPoint North America
Enabled if Microsoft MapPoint North American edition has been installed. Check this box to use MapPoint’s North American database. Will be disabled if MapPoint North America is not installed.

Use MapPoint Europe
Enabled if Microsoft MapPoint European edition has been installed. Check this box to use MapPoint’s European database. Will be disabled if MapPoint Europe is not installed.

Use geocoding extensions
If checked, the geocoding engine first searches data in user supplied extensions to the street address database and only if a match is not found
does it search the Manifold geocoding data (if installed) and then MapPoint (if used). By default, the option is turned on. See the Street Address Geocoding topic. Will be disabled if no geocoding extensions have been installed.

**Give MapPoint priority over Manifold Geocoding Database**
Check to use Microsoft MapPoint’s database to search for addresses before searching for addresses in the Manifold Geocoding Data product. If checked, Manifold attempts to find a street address in MapPoint and if a building-level match is not found searches the Manifold Geocoding Data product, if installed. Using the default choice of an unchecked box, Manifold attempts to find an address in the Manifold Geocoding Data product first and only checks the MapPoint geocoder if a building-level match is not found. See the Geocoding with MapPoint topic.

**Use the following Manifold Geocoding Servers**
A list of installed modules that support the Manifold Geocoding Server interface for generic geocoding data sources. Check the boxes to enable use of desired modules.

### Import and Export

**Detect read-only data sources for linked components**
Automatically check permissions on the source table of a linked component and make the component read-only if the source table can not be modified. On by default.

**Import data to separate folders**
Create a new folder in the project pane when importing components. Useful when importing complex components that result in the creation of many files.

**Import empty columns in tables**
When importing tables, import even those table columns that contain no values. Off by default.

**Show system tables and views in external data sources**
Show system tables (such as those embedded within Access database .mdb files) when browsing tables in databases. Most database applications hide system tables. Not checked by default.

**Trim imported strings**
Delete leading and trailing token separator characters from imported table strings.

The **Trim strings** option (just like the Trim table transform operators) removes characters listed in the Tool Properties pane’s list of token separators. By default, these are the “white space” characters consisting of the space character, tab, newline and carriage return. Note that adding any other characters to the separator list in Tool Properties will subject them to removal as well if they occur as leading or trailing characters.

### Info Bar

When a new component (other than a new map component) is opened for the first time, by default Manifold can show an info bar in the window reminding the user to verify the projection of that component. The info bar appears whether the component is opened for the first time in its own window or if it is opened for the first time as a layer in a map.

Clicking the info bar launches the Edit - Assign Projection dialog. To verify the projection without any changes simply click OK. If the projection should be changed, make the changes in the Assign Projection dialog and then click OK.

**Prompt to verify projections of new components**
Show an info bar when a new component is opened reminding the user to verify the projection of this component. Checked by default. Un-
Suppress prompt for non-default projections

Show the info bar only if the component has been imported in Orthographic projection or if it has been imported in Latitude / Longitude with coordinate locations outside the expected range (+/- 90 latitude and +/- 180 longitude). Checked by default. Only active if the Prompt to verify projections of new components option has been checked. If the prompt option is on, then un-checking this option will cause the info bar to be shown for all new components.

When Manifold imports components from formats that do not provide coordinate system (projection) information, the component will be imported using Orthographic projection by default. Therefore, the Suppress prompt for non-default projections option, if checked, is a handy way of assuring that the info bar prompt (which rapidly becomes annoying to experienced users if raised for all new components) is shown only when a new component has been imported from a format that does not store projections.

Latitude / Longitude coordinate values outside the expected range (+/- 90 latitude and +/- 180 longitude) are also a tip-off that projected data has been imported from a format that does not store projections, so Manifold will raise the info bar by default in those cases as well.

The default settings are preferred by most users, but they do not guarantee the info bar is raised only when it is required, nor do they guarantee that the info bar will always appear when it is needed. In general, because components imported from geographically-unaware formats will appear in Orthographic projection or when latitudes and longitudes are out of range the short hand rule of urging users to take a look and verifying the projection is a good rule of thumb. But it is not perfect.

For example, the info bar also will be raised when importing components from geographically-aware formats if the component happens to use Orthographic projection. But such cases usually are only a small subset of all projected components that are imported.

A more serious situation is that sometimes certain formats like shapefiles accompanied by .prj files or image files accompanied by "world" files can give enough indication of a coordinate system to cause a projection other than Orthographic to be assigned but not enough coordinate information to have all parameters assigned correctly. In that case, it could be useful to have the info bar raised to remind us to check the assigned projection in all details, but the default options settings will not cause it to be raised.

If new users will be doing a lot of imports from projected shapefiles or from formats that use "world" files, it may be a wise choice to un-check the Suppress prompt for non-default projections option. This will cause the info bar to be raised on all new components, causing some annoyance but also reminding the new users to always verify the projection of a newly-imported component.

Logging

Manifold can automatically log information to the History pane when the following options have been checked:

- **Log query execution time**
  Logs execution time of queries.

- **Log rendering time**
  Logs the time required to render a given window.

- **Log script execution time**
  Logs execution time of scripts.

- **Log transform time**
  Logs execution time for the Surface - Transform dialog, spatial overlays and topology overlays in addition to Transform Toolbar operations.

Command line switches take priority over the above settings if Manifold is launched using one or more command line options for the above.

Why have options to log the time required for something like rendering? Developers who create applications based upon Manifold are often acutely interested in creating applications that render as rapidly as possible.
They'll use timings to explore how altering different factors like those mentioned in the Performance Tips topic will affect performance.

### Miscellaneous

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Smooth freeforms at Rounding radius to use to include / exclude pixels when working with images using tools like Paint Freeform or Select Freeform.</td>
<td></td>
</tr>
<tr>
<td>Limit number of sequential approximations</td>
<td>Some computations within Manifold use a series of sequential approximations. This number gives the number of sequential approximations to compute.</td>
</tr>
<tr>
<td>Automatically list completion suggestions when editing queries</td>
<td>Automatically popup lists of possible completions when editing queries. See the Autocompletion in Queries topic.</td>
</tr>
<tr>
<td>Automatically select query records</td>
<td>When querying a drawing, automatically deselect any selected objects and then select all objects returned by the query. When a query includes more than one drawing, deselect all previously selected objects in all of the drawings and then select objects in the first drawing for which an ID column is found in the query. On by default.</td>
</tr>
<tr>
<td>Compress .map files to save space</td>
<td>On by default. Will compress a .map file using &quot;zip&quot; style compression when creating or saving a .map file.</td>
</tr>
<tr>
<td>Create empty document on startup</td>
<td>Creates a new, empty project when Manifold is launched.</td>
</tr>
<tr>
<td>Fill new pixels with current color</td>
<td>If checked, uses foreground color for new pixels added with the Add Margin transform operator. If not checked, uses transparent color for new pixels.</td>
</tr>
<tr>
<td>Make new queries ANSI-compatible</td>
<td>Use ANSI-compatible SQL to parse any new queries. Checking this box will set the ANSI compatibility option in any new queries. See the Queries topic.</td>
</tr>
<tr>
<td>Make new queries cached</td>
<td>Set the Use cache option on/off by default for new queries. See the Queries topic.</td>
</tr>
<tr>
<td>Override system data with custom config files</td>
<td>Off by default. When turned on, the system allows user-supplied configuration entities (for datums, ellipsoids, palettes, presets, styles and units) to override corresponding system entities with the same names. When turned off, the system rejects user-supplied configuration entities whose names are the same as system entities. Toggling the value of this option requires a restart of Manifold.</td>
</tr>
<tr>
<td>Process global events with scripts</td>
<td>Allows (the default) or disallows the processing of click and double click events with scripts. See the Click Events topic.</td>
</tr>
<tr>
<td>Refresh linked components after opening file</td>
<td>Turned on by default. Fetch current data for any linked tables, inked drawings, linked images or linked surfaces when a .map project file is opened. This option has effect even if a script is used to load a .map project that contains linked components. The names of any linked components that failed to refresh in the process of opening the .map file will be logged into the History pane.</td>
</tr>
<tr>
<td>Save file prior to running script</td>
<td>Off by default. A safety measure to save the .map project file before running a script.</td>
</tr>
</tbody>
</table>
Set transfer rules for new columns to Copy / Copy
If checked, changes the default behavior of transfer rules for newly created columns from Sample to Copy for both 1 to N and N to 1 transfers.

Shade new surfaces
Turns on Shading option in the View - Display Options dialog for new surfaces. On by default.

Split branched objects after transforms
Automatically decompose branched objects into separate non-branched objects after running a transform toolbar operator.

Use custom datum transformations
Use NADCON formulae and similar custom transformation methods when converting between datums in locations served by such custom methods.

Use English measurement units
Toggles between Metric units and English units. If checked, use English units.

Use GDI-compatible offscreen cache
Off by default. This option uses a lower performance method of rendering the display screen that may be used in case of buggy or incomplete video drivers. For example, some ATI-based cards have a driver bug that causes the drawing display to refresh and then go blank. To avoid triggering the ATI video bug, check this option. A better solution, of course, is to use a video card that does not have buggy drivers.

Use GPGPU technologies (NVIDIA CUDA)
On by default. Enables use of NVIDIA CUDA massively parallel processing if appropriate CUDA-capable hardware and CUDA drivers have been installed. See the NVIDIA CUDA topic.

Printing
Optimize printing of images and surfaces
When on, the system avoids rendering image and surface components in full resolution during print job setup, deferring final rendering to the printer driver, provided the image or surface can be rendered with either no re-projection or with simple scaling and shifting. This makes the size of the print job smaller and offloads the task of scaling raster images to the printer driver. Most printer drivers can automatically re-scale images and surfaces within the driver for better performance and reduced print job size. Some drivers cannot do so and will so cause the job to be printed more slowly than if Manifold renders images and surfaces. By default the option is turned on since most modern printer drivers can automatically render and re-scale. If the print job is slow or if the printer or plotter in use is suspected to be Windows unaware, try turning this option off and see if performance improves.

Print blank pages in multipage printouts
Print all pages in multipage layouts, even those that may not have any ink on them. See the Multipage Layouts topic.

Print using GDI+
On by default. If unchecked, prints using GDI mode instead of GDI+ mode. GDI is an earlier Microsoft technology. Provided for use in case of a buggy or incomplete printer driver. Printing in GDI mode does not support antialiasing or transparency for drawings. See the Layer Opacity topic for information on transparency. Curved (rotated) or labels aligned to lines cannot be printed n Windows 9x systems if the Print using GDI+ option is turned off.
Proxy Server

Allows specifying parameters for a proxy server to use while retrieving data from the Internet, for example, when using images linked from OGC WMS servers.

Connect via proxy server
Check if a proxy server is being used.

Address
URL for proxy server.

User
User name if required for proxy server.

Password
Password if required for proxy server.

Different proxy server settings may be required for different tasks. For example, at a given domain that uses a proxy at proxy.mydomain.edu a user connecting to an ECWP server might use a setting of:

http://proxy.mydomain.edu

…but for a WMS link it may be necessary to include the port:

http://proxy.mydomain.edu:8080

This depends upon the proxy server in use and how it is configured and the connection to be achieved.

Rendering

Options that control rendering of text and graphics objects, both onscreen and in certain rendered exports such as exporting layouts to AI, PDF or PS files.

Adjust display scale for monitor resolution
Automatically scale objects so that size 1 objects are 1/72 inch (one point) regardless of how many pixels that requires in the monitor resolution in use. This option also automatically scales text to preserve desired point size within component windows regardless of the Windows Display setting for Large Font / Small Font. This option also provides the same physical representation on very high resolution monitors.

Antialias lines
Use antialiasing for a smoother line appearance. On by default. When on this option also antialiasises area style patterns, area borders and the borders of text box labels. See Lines and Line Styles.

Antialias text
Use antialiasing for smoother appearance of text labels. On by default. When on this option will also antialias TrueType symbols in point styles, excepting those using halos.

Render data progressively
Enables progressive rendering so the contents of windows showing large or complex data are rendered in stages, with the system becoming responsive to other commands before rendering is completed. This is very useful with large, complex components that might take some time to render. For example, even before a large drawing finishes rendering we can begin zooming in to a region of interest. When a component is small enough to render very quickly, progressive rendering will not be noticed because the component will be rendered in a single pass. On by default.
Smooth large vector objects for performance

Checked by default. Renders large, complex vector objects with reduced detail. Results in faster rendering performance without significant degradation of visual appearance.

Scripts

Options of interest to scripting:

Cancel user interface operations after ... seconds

Specifies the number of seconds the system should wait before timing out during user interface scripting. 120 seconds by default.

Process global events with scripts

Allow scripts to process global events. On by default.

Save file prior to running scripts

Save the .map project file before running a script. Off by default.

Server Storage

Options related to Enterprise Edition only. If you do not have Manifold System Enterprise Edition installed these options will not be applicable

Cache newly shared components

Specifies whether newly shared components will be cached or uncached. By default, this option is checked so that newly shared components are cached. If this option is not checked, newly shared components will be uncached. See Cached and Uncached Components.

Get latest versions of shared components after opening file

If checked, when a project .map file containing shared components is opened the system will execute a Get Latest Version for each shared component. This will fetch the latest version from the component's Enterprise server if the component has changed since the project has last been opened. Not checked by default.

Refresh state of shared components every [ ] seconds

Specifies time interval on which Manifold will check the Enterprise server for each shared component to see if it has changed status, such as, for example becoming checked out by another user. 120 seconds by default.

Sounds

At times we may launch a very demanding command that will take some time to accomplish. Some jobs may be so computationally intensive that they may require hours or longer to run. It is often convenient to set such jobs running while we continue work on another computer; however, in such cases it is also convenient to have Manifold play a sound or otherwise alert us when the job is done.

The Tools - Options - Sounds dialog allows us to specify whether or not we want a sound to be played at the conclusion of a lengthy process, how long the process must be before a sound is played and, optionally, a .wav file from which a sound can be taken.

Play sound after lengthy operations

Check to enable sound-playing after the completion of a lengthy process.

Wait at least ... seconds

The length of time before a process is considered "lengthy." For example, if this value is set to 30 seconds any operation that takes less than 30 seconds will conclude silently.
Sound file
An optional .wav file to use for sounds. Leaving this box blank or choosing a file other than a .wav file will result in use of the default "beep" sound. Use the Play button next to the browse button to play the specified file to preview how it sounds.

It's fun to browse a Windows system for .wav files to use for sounds. Windows ships by default with many sounds.

Status Bar
Status bar options configure the status bar at the bottom of the Manifold display. Changes take effect immediately. See the Getting Started topic for notes on the status bar.

Component-specific information
Readouts relevant to particular components, such as the number of selected objects (appears for drawings for example, but not for comments components).

Coordinate system
Report the coordinate system (projection) in use.

Current location
Location readout for the mouse cursor using various ways of reporting coordinates. Options with examples beginning with the default are:

- latitude / longitude:
  122°19.701' W 37°34.119' N
- latitude / longitude (decimal):
  -122.3816 37.5597
- latitude / longitude (deg-min-sec):
  122°19'04" W 37°33'25" N
- projected coordinates:
  550833.8339 4155957.9227
- USNG coordinates:

Current modes for mouse, selection and tools
Show mouse status such as snap mode, status of selection mode and the current command being used.

Current scale
Show scale on status bar using Report setting.

Report
Choose style of scale or size status readout. Scale is accurate only for projected components. Options are:

- absolute scale (#:#) - Absolute scale in 1:xxx form.
- relative scale - Relative scale as ratio between one centimeter or inch and the scaled number of meters/kilometers or feet/miles, depending on setting of the Use English measurement units option.
- horizontal extent - Shows the horizontal size of the current window.

Note: The relative scale option will automatically switch from large units to small. For example, in metric units once the scale falls below 1 centimeter to 1 kilometer it will switch to reporting the number of meters per cm.

User Interface

Grid lines in tables
Show horizontal and/or vertical lines in tables to separate rows and columns.

Paint palette colors using []
The size of color well boxes shown in palette
<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pixel boxes</td>
<td>windows for palette images.</td>
</tr>
<tr>
<td>Zoom magnification factor</td>
<td>Specify the change in magnification to use when zooming in or out in the range from 1.1 to 4.0. The default value is 2.0.</td>
</tr>
<tr>
<td>Apply table cell editing to all selected records</td>
<td>On by default: editing one cell in a set of selected records will apply that value to all such cells in the selected records.</td>
</tr>
<tr>
<td>Automatically set insert mode</td>
<td>When editing drawings, automatically choose Create Areas, Create Lines or Create Points depending on which shape creation tool is used. See Adding Shapes.</td>
</tr>
<tr>
<td>Automatically set paint mode</td>
<td>When editing images, automatically choose Paint Areas, Paint Lines or Paint Points depending on which shape creation tool is used. See Image Editing Tools.</td>
</tr>
<tr>
<td>Autoscroll window on edit or selection operations</td>
<td>If the mouse is in a command mode (such as drawing a selection box) automatically pan (scroll) the window when the mouse nears the edge of the window. Indispensable in some operations and insufferable in others if inappropriate options are specified. On by default.</td>
</tr>
<tr>
<td>Margins</td>
<td>Gives the distance in pixels from the edge of the window at which autoscroll occurs. Set to 5 pixels by default.</td>
</tr>
<tr>
<td>Distance</td>
<td>The distance in pixels the window is scrolled for each autoscroll. Set to 10 pixels by default.</td>
</tr>
<tr>
<td>Require Alt key</td>
<td>Disables autoscroll unless the Alt key is pressed. Off by default.</td>
</tr>
<tr>
<td>Highlight entire line in script window</td>
<td>Changes the background color of script lines containing bookmarks, breakpoints or the current execution line. Breakpoint colors override bookmark colors, so if a line contains both a bookmark and a breakpoint it will be highlighted with the breakpoint color. The current execution color overrides both breakpoint and bookmark colors.</td>
</tr>
<tr>
<td>Open newly created component</td>
<td>When a new component is created in the project pane, automatically open it in a window.</td>
</tr>
<tr>
<td>Pop up Project pane when creating or opening a file.</td>
<td>Automatically pops open the Project pane when creating or opening a component.</td>
</tr>
<tr>
<td>Quiet system activity indicator</td>
<td>On by default. Causes the system activity indicator in the lower right corner of the display to show a 3D “bump” when the system is busy. Unchecking this option causes the system activity to toggle from a large green dot to a red dot when the system is busy.</td>
</tr>
<tr>
<td>Restrict mouse wheel to only operate over focused window</td>
<td>On by default. Disables the wheel in wheel mice when the mouse pointer is not over the window that has the focus. This prevents accidentally changing the current scale via the scale combo box in the Navigation toolbar and other unintentional actions using the mouse wheel.</td>
</tr>
<tr>
<td>Save last used view in component</td>
<td>If checked, zoom to a view called Startup in the views pane if such a view exists, or to the most recently used view when opening a drawing, image, labels, map, profile, surface or theme window. On by default. If this option is not checked, then on opening the component will be zoomed to fit the display window.</td>
</tr>
</tbody>
</table>
Show grid lines in Variables and Watches: Show horizontal and vertical lines in these panes for greater visual separation of cells. Off by default.

Show splash screen: Display the Manifold System splash screen when Manifold launches.

Use Explorer-style menus and toolbars: Removes all colors from toolbar buttons until mouse hovers over them as in IE. Since Manifold does not use gaudy icons like IE the effect is bland and not recommended. Takes effect the next time Manifold is launched.

Use selection style for palette: Use defined selection style to show which palette box is chosen in a palette window used with palette images. If not checked, a plain border style will be used.

Image Menu

Image Menu

The image menu appears when the focus is on an image window or an image layer is active in a map. Commands listed below will appear either under the main Image menu or under submenus such as Adjust or Effects. Commands are enabled for RGB or RGBA images. To use these commands with other types of images, first convert them to RGB or RGBA images.

Open Palette: Enabled for palette images. Open the palette for this image.

Dither: Uses a smaller number of colors in an image while preserving a perceptual effect through the use of dither patterns.

Quantize: Convert image to the specified number of colors using enhanced or standard methods.

Resize: Change the size of the image using desired interpolation method.

Convert To: Convert images between grayscale, palette, RGB or RGBA images.

Adjust Menu

Color Balance: Adjust RGB color values for Shadows, Midtones or Highlights.

Brightness / Contrast: Change brightness and contrast.

Hue / Saturation: Alters hue, saturation and lightness.

Invert: Invert pixel channel value. Creates a "photographic negative".

Equalize: Alters individual pixel brightness so there is an equal number of pixels at all brightness levels.

Gamma: Change mid-tone color brightness.

Threshold: Forces grayscale pixels to white, black or unchanged based on a histogram.

Threshold Color: Like Threshold but applies to each RGB channel individually.

Posterize: Convert image to a limited number of colors for a "poster"
Effects Menu

**Colorize**
Adjust saturation and hue while keeping intensity the same, as if a color were applied to a grayscale version of the image.

**Gaussian Blur**
Apply Gaussian bell curve blurring to create shadows, halos and transitions.

**Motion Blur**
Streaked effect in the desired direction.

**Diffuse**
Moves pixels by swapping them in a "random walk."

**Filter**
Applies convolution filters, either custom filters or a choice from numerous presets.

**Fluoresce**
Alter saturation and lightness in asymmetric ways to cause some colors to appear unusually bright.

**Noise**
Add random monochromatic or color pixels.

**Relief**
Add highlights and shadows to give a 3D effect to 2D images.

**Simplify**
Aggregates pixels into larger clumps for a pointillist or mosaic tile effect. Can also remove small dots in cartographic work.

**Tile**
Convert image into rectangular tiled regions of appropriate color.
Image - Brightness / Contrast

Allows alteration of brightness and contrast of selected pixels or over the entire RGB or RGBA image if no pixels have been selected. **Brightness** makes the image lighter or darker overall, while **Contrast** either emphasizes or de-emphasizes the difference between lighter and darker regions. See the Colors as Hue, Saturation and Brightness topic for more information on brightness.

- **Brightness** Increase or decrease the brightness of pixels. Low brightness will result in dark tones while high brightness will result in lighter, pastel tones.

- **Contrast** Increase or decrease contrast. Increasing contrast increases the apparent difference in lightness between lighter and darker pixels.

- **Preview** Check to see effect in action.

These commands are also available on the Transform Toolbar for images as the **Brightness** and **Contrast** transform operators. However, when used from the transform toolbar the effects are immediate with no preview possible.
**Image - Colorize**

Adjusts hue and saturation while keeping intensity the same in RGB or RGBA images. The resultant effect will appear to apply the designated color to a grayscale version of the image.

**Preset** colors allow choice of a standard range of named colors, as well as saving one's own colors as presets. Because there are many presets and because at times very large images may be manipulated in Manifold, choosing a preset does not apply that preset's color values to the slider bars until the **Apply** button is pressed. This makes it possible to browse the presets without applying the color values to the main image regardless of whether the **Preview** box is checked or not.

The selected area of the image (shown using **Border** selection style) has been colorized with the **Dark Orchid** preset color.

Colorize is often used to add color tones to gray scale images. The image should first be converted to an **RGB** image using **Edit - Convert to** if it is not already an RGB image.

Suppose we wish to colorize a circular region in this overhead view of downtown Palo Alto near the 525 University Avenue office building. First, we select the circular region (shown using **Border** selection style). If we did not select a region the colorize effect would be applied to the entire image.
We click the **preview** box and move the **Green** slider to the right to increase green values and the **Red** and **Blue** sliders to the left to decrease red and blue values. The result is colorization into green tones.

The final result is a convenient means of highlighting a particular region within an image.

A more sophisticated effect may be achieved by choosing **Edit - Select Inverse** to select all the pixels **not** in the original circle, and to then use the **Brightness / Contrast** control to increase brightness while decreasing contrast slightly. This will "wash out" the rest of the image and make the round green region stand out even more.

**Colorize and All-Black Images**

Because colorize keeps intensity the same attempting to colorize an all-black image will result in no change. Black is zero intensity for all color channels. To use colorize to change the color of a solid color layer it must be some visible shade of gray or white.
Image - Color Balance
Adjusts RGB color values in an RGB or RGBA image for Shadows, Midtones or Highlights.

Tones Choose from Highlights, Midtones or Shadows

Red Value for Red channel.
Green Value for Green channel.
Blue Value for Blue channel.

Preserve Luminosity Adjust all three channels slightly to preserve perceived lightness / darkness.
Preview Check to see effect in action.

Select the tonal range to be affected and adjust the slider. Switching tonal ranges in the choice box will preserve any changes made in the other tonal ranges. For example, lowering the Green value with the choice box set to Midtones, and then switching to Shadows in the choice box will still have the Midtones value changed to the lower value, as can be seen by switching back to Midtones. The tonal range refers to the brightness of colors.

In complex color images,

- Moving the Red slider left and right will appear to change the tonal variation from Cyan to Red tones.
- Moving the Green slider left and right will appear to change the tonal variation from Magenta to Green tones.
- Moving the Blue slider left and right will appear to change the tonal variation from Yellow to Blue tones.

The above effects occur because, for example, turning Blue color all the way down leaves only Red and Green tones which make up Yellow. See the discussion of Channels in the main Images topic.

The above illustrations show the original image in the center with Midtones in the choice box and the Blue slider moved to the left for the left image and moved to the right for the right image. Note that the increasing blue to the right or decreasing blue to the left ("increasing yellow") does not affect the white clouds, which are "highlights" or dark shadows as much as it does the middle range of color tones.
Image - Create Index Drawing

When an image library is open the Image - Create Index Drawing command is enabled. This command allows us to automatically create a drawing that contains areas showing the extent of each individual image file that makes up that image library together with desired information about each image file, such as the name of the file, the path to that file's location and the type of file.

Index drawings are used in a variety of applications. For example, we might not wish to display all of the images in an image library but need to fetch an image that is part of the library. An IMS application, for example, might show a variety of vector layers and use an index drawing to show where imagery is available in a particular region. The application could be programmed so that a user who wants to see that imagery can click within an index drawing area to pop open the corresponding image in a new window or to make it visible in a map window.

To create an index drawing for an image library:

1. Open the image library.
2. Choose Image - Create Index Drawing.
3. Provide a name and an optional description for the new drawing.
4. Choose which columns should be added to the drawing's table. Press OK.

### Controls

- **Name** The name of the new index drawing.
- **Description** An optional description to appear in the drawing's properties.
- **Select All** - Check all columns.
- **Select None** - Uncheck all columns.
- **Select Inverse** - Uncheck all checked columns and check all unchecked columns. A fast way to use all but one column: click Select None, check the one column not desired and then click Select Inverse.
- **Columns** Check which fields are to appear as columns in the drawing's table. The columns available will depend upon the method used to assemble the image library. The
The illustration above shows columns available when assembling an image library using image tile file names to position tiles.

**Include autogenerated images**  
Off by default. Checking this box will add intermediate level images if these have been automatically generated for this image library.

**Example**

Let's create an index drawing for the image library used as an example in the Image Libraries topic.

The image library is called **Bay image** and is assembled from nine .tif format files using accompanying .xml files to position the tiles.

It appears in our project pane as a linked image. The first illustration above shows the image library as it appears in a **Map** component.
With the focus on the opened map window, we choose *Create Index Drawing* in the *Image* menu. The *Create Index Drawing* dialog opens. The *Name* will be filled in for us with a default suggestion for the name of the new drawing derived from the name of the image library. We will use this name and choose other options as seen above. Press *OK*.

The result is that a new drawing appears in the project pane.

If we click open the drawing's table we can see it has nine records in it, one for each area object, that show the extents of the images that make up the image library for which the index drawing was created. The columns that appear in the drawing's table are the columns we selected in the *Create Index Drawing* dialog.

To see what the drawing looks like, we can drag and drop it from the project pane into the open map window.
Our first impression is somewhat underwhelming: the index drawing is formatted using default drawing formatting so each area in the drawing has an opaque background. We can't see anything behind this drawing because of the opaque color of the area backgrounds.

That takes but a second to change by using the format toolbar to change the formatting of area background to transparent color.

While we are at it, we'll change the area border color to something bright and visible, and we will add a labels layer that automatically creates labels from the Filename column.
The end result is a map that shows a labels layer and our new index drawing above the image library layer. The rectangular areas in the index drawing (now seen only by their borders) show the extents of each of the nine image tiles that make up the image library. The labels layer shows the name of each tile.

**IMS Example**

Once we have information about images within an index drawing we can proceed to do all sorts of wonderful things. Suppose, for example, that we have a Manifold IMS web site at [http://www.mydomain.com](http://www.mydomain.com) and we would like visitors to be able to click open an image by clicking into a map.

We can open the drawing’s table and then use Manifold’s ever-useful **Edit - Replace** command to edit the path into an appropriate URL path. (Experienced IMS players know already where we are going with this example...)

We then change the type of the column to **URL** and we also name this column **URL** so that it can be recognized by the **Hyperlinks** option in the **Export Web Page** dialog we will use when exporting the project as an Internet Map Server web page. The **Hyperlinks** option gives an IMS web page template the ability to automatically launch a hyperlink when an object containing that hyperlink is clicked.

We take the images that made up the image library and we copy them into an **images\bay** folder within the **InetPub\wwwroot** website folder on the web server that runs our **mydomain.com** web site. Because we have had the wisdom to read the IMS topics in this documentation, we also know to make sure that the **IUSR_** account for the web server has read access to those image files as well as read access to the folders that contain them.
The IMS site we create has a variety of drawing layers in it with the index drawing at the top, now with borders formatted in a pretty green color. None of the layers are clickable (set these properties in the layer restrictions for the map component) except the index drawing layer. In this example we do not show the image library as a layer.

Note that even though the areas that comprise the index drawing have been formatted with transparent background color, those areas are still there. Clicking within the borders of the rectangular areas is still a click onto that area object even though it may be transparent.

Whenever someone clicks onto one of the index drawing areas, Manifold IMS will hop to attention, grab the corresponding URL hyperlink and in a flash launch that URL within a new browser window or other program, as appropriate, to display that image.

It’s true that our use of .tif images for this IMS example is not the most intelligent thing, since most browsers will not immediately display a .tif but instead are configured to launch some image viewing application whenever they are fed a URL that ends in a .tif file. For a “real world” web site we might have preferred to use an image format such as .jpg or .png that could always be immediately viewed in a new browser window.

Likewise, the default templates in Manifold IMS are not necessarily the best for building websites with hyperlinks in them, since each click not only launches the URL but also (since the Center tool in the default templates is always on by default) will center the display to the position clicked. Many designers prefer to have their sites act that way but if different behavior is desired one can always use the sample web applications published at the manifold.net site as a guide to creating different navigation tools.

The IMS example discussed above is a fairly common use of both image libraries and index drawings. Public utilities, for example, often have in addition to their vector GIS drawings a large amount of legacy information in the form of scanned blueprints and other scanned images. Utilities will often georegister those scanned images so they may be used in a GIS environment. However, because images are so much less efficient to work with than drawings the utility will not use those images except when it is absolutely necessary to view them.

In such cases, a utility might create an image library consisting of the various scanned images it has and then create an index drawing. The index drawing is a fast, “lightweight” layer that can be used in the utility’s GIS work to show where images are available and to provide a convenient way of locating an image when it is required.

Creating Labels from Fields
Image - Diffuse

The Diffuse command moves pixels in RGB or RGBA images by swapping them in a "random walk." Reapplying Diffuse several times will move pixels further and further away from their original positions. Diffuse is used to apply artistic effects. If a selection is present, Diffuse will ignore any unselected pixels. Diffuse will also ignore invisible pixels.

Level  The number of times diffuse should be reapplied.

Preview  Check to see effect in action.

The mages below show a zoomed-in view with one application of Diffuse as well as a view after several applications of Diffuse.

Note how pixels "drift" at random from their original positions with repeated applications of Diffuse.
When used with photographic images, **Diffuse** provides a pixelated, "dry brush" painterly effect. The illustration above shows the effect after using a level of **9**, applied to the sample **bronze** image that was previously altered using the fluoresce command.

If a selection is present, the action of the **Diffuse** command is limited to the selected pixels.

For example, in the image above a circular region was selected and then **Diffuse** was applied.
Image - Hue / Saturation
Allows simultaneous changing of hue, saturation and lightness in RGB or RGBa images. See the Colors as Hue, Saturation and Brightness topic for more information on these concepts.

**Hue**  Shift color of all pixels clockwise or counterclockwise about the color wheel.

**Saturation**  Increase or decrease color saturation. Fully-saturated colors are very bright, while low saturation are grayish.

**Lightness**  Increase or decrease lightness. Zero lightness results in all black pixels, while full lightness is white.

**Preview**  Check to see effect in action.

The **hue** slider shifts the colors of all pixels in a plus or minus direction around the color wheel. Plus or minus 180 degrees are equivalent. Blue tones shifted 180 degrees will end up yellow, as may be seen in the blue sky in the sample pictures. Use **hue** to shift images slightly, such as more or less red or blue throughout the image.

The **saturation** slider increases or decreases the intensity of colors, ranging from white (no saturation) to grayish colors to bright, vivid colors (full saturation).

The **lightness** slider controls how light or dark each pixel as compared to an absolute gray scale from black to white.

Increasing lightness goes from black to colors to white.

See also: Colors as Hue, Saturation and Brightness

**Note:** The illustrations above are shown using only 256 colors and thus will appear "grainy" as compared to true colors in Manifold images.
Image - Dither

This command replaces pixels in an RGB or RGBA image with a "dither" pattern that approximates colors of pixels by using a smaller number of colors in a mixed pattern. The dither colors are selected so that the human eye interpolates between them to get the desired color impression at that location.

Palettes

Adaptive Sample colors appearing most frequently in the image and use these to choose a best fit to the given number of colors from the entire RGB space.

Linear Choose colors that are evenly spaced in the RGB cube space for the given number of colors.

Photoshop Use the 90-color Photoshop swatches palette. Handy for many restricted-color graphics arts images.

System Use the 256-color Microsoft Windows system palette.

System (Mac) Use the 256-color Apple Mac system palette.

VisiBone 2 Use the VisiBone web designers palette.

Web Use standard 216-color palette included by default in all web browsers.

Palettes used by other applications and systems are provided so that images destined for those systems can be created using an exact match of palettes.
The Download command appears when the focus is on a window for an image linked from an external image server such as an OGC WMS image server, a Microsoft TerraServer image server or a Manifold Image Server compatible third party module such as Google. The command allows automatic download of all tiles available for the image at any level of resolution available. Tiles will be assembled into a single image at each resolution level selected.

Note that before the Download command appears, we must have already used File - Image - Link to create a linked image from an image server such as TerraServer or an OGC WMS server. The maximum detail available in the downloaded image will have been set by the choices made when initially linking the image, such as the use of the Min Scale parameter in the TerraServer dialog or the Size parameters in the OGC WMS dialog.

Select All - Check all the boxes in the levels pane.
Select None - Uncheck all the boxes in the levels pane.
Select Inverse - Check all unchecked boxes and uncheck all checked boxes in the levels pane.

(levels pane) Check levels to be downloaded. The Level column reports the resolution in pixels at each level. The Tiles column reports the total number of tiles as well as the approximate number of tiles already linked at each level and thus available from cache, if caching is on (the default) for faster download.

(status bar) The number of tiles to be downloaded of the total number of tiles available with the current set of levels checked. The number to be downloaded is in addition to those already in cache and so provides a useful guide when the connection to the image server is slow.

The image download process will run in background to allow other work to proceed while the image is downloaded. Take care not to capriciously select very detailed levels for download if your connection to the image server is very slow. Downloading levels of an image linked from a remote image server proceeds from the least detailed levels to most detailed levels. This provides a reasonable chance of getting at least some useful, complete levels in case a connection is interrupted.

Images may be downloaded at a variety of detail levels. The most detailed level that may be downloaded will be set by the parameters specified when linking the image (Min scale in the case of TerraServer images and Image size in the case of OGC WMS images). The least detailed level will be set by the least detailed data level available on the server. The Download dialog allows us to choose which level of detail we want between the most detailed and the least detailed available and to download the resulting image into a local image so that subsequent work with the image is faster or more convenient.

For example, we could use the Download dialog to fetch a complete image from the server so we can later work with that image when disconnected from the server. We might also use the Download dialog to download all tiles in the most detailed image level prior to exporting the image to a local file, perhaps as an ECW image.

Image - Download and Image - Relink / Unlink Compared

An image linked from an image server may be converted to a local image within the project either by using the Image - Unlink command or the Image - Download command. The Unlink command converts the existing linked image to a local image at whatever resolution is currently in use. The Download command may be used to automatically fetch all image tiles at any available resolution to create a local image at that resolution.

Images linked from external servers normally may also be exported to image files. In that case, the exported image will be the same as that which would be obtained by unlinking the linked image.

Note that exporting or unlinking an image linked from an image server will only use the data already downloaded from the server and will not attempt to download any more data. It will also only use the data for the most detailed image level. It is usually a good idea to use Image - Download to check how much data has already been downloaded for the most detailed image level prior to exporting or unlinking the image.
Another way to create a local image from a linked image is to open the linked image and then to use the keyboard F6 command or the Tools - Make Image command. The Make Image dialog allows us to create a local image in several different ways from the linked image without unlinking the linked image. For example, we can use this command to create an image of the displayed window or of the entire linked image at a desired number of pixels or scale.

**Very Important**

Before using Export with an image linked from an image server, see the Very Important discussion in the Image - Unlink command.

Linked Images from OGC WMS Servers  
Linked Images from TerraServer  
Image - Relink / Unlink  
Tools - Make Image
Image - Equalize

**Equalize** builds a histogram of colors used in all pixels in the RGB or RGBA image from the brightest to the darkest and then alters colors of pixels in between so there is the same number of pixels at all brightness levels.

**Level**
Offset the brightness level higher or lower from the default 50% level. Increasing level results in higher overall brightness.

**Preview**
Check to see effect in action.

This command is also available on the Transform Toolbar for images as the **Equalize** transform operator. However, when used from the transform toolbar the effect is immediate with no preview possible. In the transform toolbar version the parameter specified is used as the level.

**Example**

Starting with the **schloss** sample image applying an **Equalize** with a level of 0 (seen above) is similar to the Auto Level transform. It provides better balance between light and dark tones to give more character to what started as a slightly washed-out image. Applying **Equalize** with a level of -76 shifts the tones to darker levels for an almost "sunset" effect as seen below.
The **Filter** command works with RGB or RGBA images and exposes the internal functioning of many commands in the Transform toolbar and allows us to add new, custom commands using convolution filters. Most users will apply the commands in the Transform toolbar without ever examining their matrix values in the **Filter** command. However, for those users who are so inclined, the **Filter** command provides an “open door” to altering existing filters and creating new ones. If a selection is present, **Filter** will ignore any unselected pixels. **Filter** will also ignore invisible pixels.

Many image effects are created through a mathematical process called **convolution**, where the brightness values in all channels of each pixel are recomputed based on the values of surrounding pixels. The rules for how each pixel’s brightness values should be computed are given by a matrix of numbers, where the central number gives the brightness of the pixel and the other numbers set forth how values from surrounding pixels should be multiplied into the convolution.

Choosing different numbers for the convolution matrix results in a very wide range of visual effects such as sharpening, blur and so on. Manifold provides a 5 x 5 matrix, where each pixel may be adjusted based on reference to 24 surrounding pixels. This convolution matrix will be applied in turn to each pixel in the image.

**List Box**  Choose a preset filter from a list. Choose **Custom** to create a new filter.

**Apply**  Load the convolution matrix with the numbers for the filter currently shown in the preset box.

**Save As…**  Save current convolution matrix as a preset filter.

**Delete**  Delete previously-saved preset filter or disable factory preset.

**Matrix boxes**  Values for convolution matrix calculation.

**Preview**  Check to see effect in action.

The list box at the top of the dialog allows choice of a filter from many preset filters. Because there are many presets and because at times very large images may be manipulated in Manifold, choosing a preset does not apply that preset’s convolution matrix numbers to the matrix until the **Apply** button is pressed. This makes it possible to browse the presets without applying their convolution matrix to the main image regardless of whether the **Preview** box is checked or not.

The **Filter** dialog has a choice box at the top for preset filter effects. Choosing **Custom** allows us to enter our own values to create custom filters. In addition to appearing in the **Filter** dialog, any new custom filters will appear as operators for use in the Transform toolbar.
Creating a Custom Filter

1. Choose custom in the choice box.
2. Enter a value for the center box. This is the brightness multiplication value for the target pixel. Most values used are quite small, almost always less than 20.
3. The boxes surrounding the center box represent pixels surrounding the target pixel. In each box, enter the convolution multiplication value to use for that pixel. For example, to multiply the brightness value by 3 of the pixel immediately to the left of the target pixel, place the number 3 in the box immediately to the left of the center box.
4. Not all boxes need to be filled. Boxes left empty will cause the pixels they represent not to be used for the convolution calculation.
5. Enter the value for scale to be used. Convolution works by multiplying the brightness values of pixels used by the number in their box and then adding up the result. This result is divided by the scale number. Larger scale numbers result in less overall brightness.
6. Enter the value of offset, if any, to be used. The offset number is added to the brightness values computed as a result of the convolution divided by the scale. Positive numbers for offset increase overall brightness. Negative numbers decrease overall brightness.

Examples

The following examples all apply different filters to the image of Tokyo airport above, shot from the Landsat 7 satellite.

Difference East

The Difference East filter subtracts values from the West and adds them to the East. This increases the brightness values where an edge difference exists to the East.
The **Low Pass 1** filter ends up eliminating changes that are only a pixel wide, and so blurs the image. Note how the convolution values surrounding the central value are all the same as the central value. Three different low pass filters provide differing values for the matrix.

"Low frequency" details are those where there is slow change from pixel to pixel. "High frequency" details are those where there is rapid change from pixel to pixel. The "low pass" filters are so named because they allow low frequency changes to pass but block high frequency changes.
The **High Pass 1** filter allows high frequency details to pass and blocks low frequency details.

Note how the image of Tokyo airport has had small changes from pixel to pixel emphasized by the high pass filter. Three different high pass filter presets provide differing matrix values.

**Edge Pixel Effects**

Because matrix filter effects work by convolution using values that surround a central pixel they raise the question: what to do with pixels on the very edge of the image, where there are no adjacent pixels on one or more sides to participate in the matrix? There are two approaches used by raster image editing packages. One approach is to simply leave pixels on the edge unchanged.

As may be seen above illustration, a zoomed in view of the result of the low pass filter, this is the Manifold method and is also the approach used by most professional image editing packages.
Another possible approach is to apply the matrix effect to edge pixels as if they were surrounded on the "empty" side by black pixels. Manifold does not take this approach because it results in inaccurate effects with edge pixels. If desired, an image can always have a black or other color border drawn about it if such an "approximate" effect is desired for edge pixels. In this way, the Manifold approach allows users to choose how they wish edge pixels to be treated.

5 x 5 Matrices

All preset convolution matrices in Manifold are 3 x 3 matrices: only the central value and the immediately adjacent pixel value boxes have values in them. All other values are zero. Surprisingly, most classic image manipulation effects may be achieved with 3 x 3 matrices.

If desired, we may create filter effects that employ 5 x 5 matrices by filling in the additional boxes with values. This will require longer computation time, but allows finer control over the convolution computation. Filtering with a 5 x 5 matrix that contains zero for boundary values will automatically switch into 3 x 3 mode for better performance (since a 5 x 5 matrix with zeros in the outermost boxes is equivalent to the 3 x 3 matrix that is surrounded by the zeroes).

Continued Education

The above three examples are just three of many filters provided with Manifold. Review of the other filters in the preset list box combined with experimentation using new, custom filters is a good way to learn how various convolution matrix-based filters work.

In addition, there are news groups and lists on Internet in which image manipulation effects are discussed. Participation in such groups and lists together with creative use of a good search engine will provide many sources of information on using and creating convolution matrix filters.
**Image - Fluoresce**

*Fluoresce* is a fun effect intended for artistic usage with RGB or RGBA images. It alters the lightness of colors in an asymmetric way so that some color ranges will appear unusually bright. A saturation control is provided since the next step is often adjustment of saturation.

- **Saturation**: Increase or decrease color saturation. Fully-saturated colors are very bright, while low saturation are grayish.
- **Lightness**: Increase or decrease lightness using differential fluorescence effect.
- **Preview**: Check to see effect in action.

Effects will vary depending on the image. The illustration above shows the sample *bronze* image with lightness lowered and saturation increased.

For artistic purposes, this effect works best with images where there is a great difference between very bright areas and other areas, such as the image above.
The image on the left shows the effect with lightness decreased for a fluorescent effect and the image on the right with lightness increased for a "blueprint" look.
**Image - Noise**

This command adds the desired amount of noise to RGB or RGBA images in the form of random color or monochrome color changes per pixel. Such changes will be often be perceived as adding small line segments, since human perception will attempt to "organize" random noise into distinguishable features.

- **Amount**  
  Move the slider to increase or decrease the amount of noise. Alternately, enter a value from 0 to 255 directly into the value box.

- **Monochromatic**  
  Check to add monochromatic noise only. This changes the lightness values of pixels without shifting their hues.

- **Preview**  
  Check to see the effect previewed in the image.

The image at left shows color noise, while the image at right has the same amount of monochromatic noise.

This command is also available on the Transform Toolbar for images as the **Add Noise** and **Add Noise(Mono)** transform operators. However, when used from the transform toolbar the effect is immediate with no preview possible.
Image - Gamma
Gamma is a measure of mid-tone color brightness. Changing gamma will result in a perceived image difference that is similar to changing the brightness. Used with RGB or RGBA images.

**Gamma**  
Increase or decrease gamma. Increasing gamma will increase overall brightness with a slightly greater effect on midtones.

**Preview**  
Check to see effect in action.

This command is also available on the Transform Toolbar for images as the **Gamma** transform operator. However, when used from the transform toolbar the effect is immediate with no preview possible. In the transform toolbar version the parameter specified is used as the Gamma level.
**Image - Gaussian Blur**

A Gaussian probability curve is the classic bell-shaped curve with a higher probability in the center of the curve and lower probabilities to either side. A Gaussian blur effect takes each pixel in an RGB or RGBA image and mixes it with adjacent pixels with Gaussian probability so that the pixel has great effect near its original location and less effect (in a bell curve shaped way) farther away from its original location. If a selection is present, the Gaussian blur will ignore any unselected pixels. Gaussian blur will also ignore invisible pixels.

- **Amount**  Number of pixels to blur to either side.
- **Preview**  Check to see effect in action.

This command is also available on the Transform Toolbar for images as the **Gaussian Blur** transform operator. However, when used from the transform toolbar the effect is immediate with no preview possible. In the transform toolbar version the parameter specified is used as the amount of pixels to blur.

**Example: Adding a Drop Shadow**

Gaussian blurs are most often used to create "drop shadow" effects.

Suppose we have an image layer that contains just the monument clipped out of our standard **bronze** sample image. We would like to add a drop shadow.

We begin by making a copy of the layer, selecting the monument only and then using Hue / Saturation to turn the **Lightness** all the way down. This makes the monument all black.
We next apply the Gaussian Blur effect, using an **Amount** setting of 5. The farther the "shadow" is supposed to be from the image, the greater the **Amount** should be for a credible effect.

We then position the initial layer over the drop shadow layer and then move either the shadow or the upper image so that the shadow is slightly offset. Drop shadows are often used to create the "cardboard cut out" effect seen at the bottom of the monument. If we wish to avoid this effect we can feather the bottom of the monument by applying partial transparency to the bottom with a partial eraser (assuming the image is an RGBA image in which partial pixel transparency is possible).

**Example: Adding a Halo**

Gaussian blurs are also used to create "halos" that set off images. There are two ways of doing so. The easiest way is to take the black blurred shadow and to colorize it and to then use the colorized "shadow" as a halo.

Here is a slightly longer version that shows the steps more explicitly.
If we take the black and white image created by reducing lightness, we can invert it to get a white image (shown here on a black background, since otherwise the white image would be invisible against a white background).

Next we use Colorize to convert the image to bright yellow. We did this by turning the Blue slider all the way down and the Red and Green sliders all the way up in the Colorize dialog.

We can now apply the Gaussian blur to blur the yellow image.
Here is the completed composition. The original image is in a layer above the yellow image, which has been offset slightly upward and to the left. We have also used three other effects:

- The saturation in the bronze monument has been increased to provide more vivid colors.
- The bronze monument is an RGBA image. We've used the eraser to partially erase the bottom part of the image to feather it into the background by virtue of increasing transparency.
- So the yellow halo does not show through the partially transparent monument image, we have erased most of the bottom half of the yellow halo to an even greater degree than the monument.

**Drop Shadows in Maps**

Drop shadows underneath image layers can add striking depth to maps.

The illustration above shows four image layers above several drawing layers in a map. The Manifold logo and text are both in separate layers and their shadows underneath are drop shadows in RGBA image layers created using Gaussian Blur. Both drop shadow layers have had transparency increased so their shadows are not so obvious. It is especially important when adding drop shadows to text to use a light touch. Increase transparency so there is barely a hint of shadow for a better effect.

Use drop shadows with logos, with text in image layers and to provide a "drop shadow" for photographs or other images that may be assembled "on top" of the map.

To create the image above, we zoomed into the map, made a screen shot, pasted the screen shot into a new image and then cropped the image down to the size of the detailed view desired. This image went into a layer in the map. We made a copy of the layer, turned the lightness down to zero to create a black square that was
exactly the same size as the cropped detail and then used Gaussian Blur on this black square to create a drop shadow. Finally, we offset the drop shadow and added the A and B labels.

See the Cookie Cutter a Large Image with Transfer Selection example topic for a detailed description of how to create a drop shadow in a geographic map.

**When a Selection is Present**

If a selection is present the Gaussian blur command will operate only on selected pixels.

For example, in the image above a circular region was selected and Gaussian blur applied. Only those pixels in the selected region were blurred.
Image - Invert

The Invert command is used to invert color values in pixels in grayscale, RGB or RGBA images. The Invert command is available in two forms: Invert and Invert At. Invert simply switches 0 to 255 and 255 to 0 and likewise switches mirror-fashion all values in between. Invert At accepts a parameter value that will stay unchanged and maps all values less than the parameter value to mirrored values greater than the parameter value and vice versa.

- **Center** Center point of the inversion (by default 128).
- **Preview** Check to see effect in action.

This command is also available on the Transform Toolbar for images as the Invert and Invert At transform operators. However, when used from the transform toolbar the effect is immediate with no preview possible. The parameter for Invert At is used for the center point of the inversion.

In a simple black and white image, using 0 for black and 255 for white, a near-black pixel value of 5 will be converted to 250, or near-white. The result is a photographic negative image.

For RGB color images or any other image with more than one channel this process is applied to each channel. If a pixel has a high blue value and low red and green values (like the blue sky in our sample image), the blue value will end up low and the red and green values will be high to result in a yellow tone.

The Invert At command includes a slider bar that allows setting the center point of the inversion process. Leave it at 128 to achieve a normal, symmetric inversion as discussed above. Increasing the center point increases the brightness of the inverted image, while decreasing the center point reduces the brightness of the inverted image.

The above example shows default inversion with a standard center point of 128 as well as brightened and darkened inversions at center points of 192 and 64 respectively. The center point control is provided because negatives are often unexpectedly light or dark and require immediate adjustment to suit one’s taste. Using the Invert command is effectively equivalent to using an Invert At command with a center point of 128.

**Comments**

The difference between the two commands is subtler than simply providing a center control for Invert At. The difference between the two is that:

- Invert always maps 0 to 255 and 255 to 0 (and, of course, inverts all other values in the middle), while
- Invert At with a center of 127 maps 0 to 254 (not 255) and 255 to 0, and
- Invert At with a center of 128 maps 0 to 255 and 255 to 1 (not 0).

The above may seem like splitting hairs, but when using Invert with surfaces the difference between 0 and 1 and 254 and 255 may be very significant.
Image - Motion Blur

**Motion Blur** provides a streaked blur effect as if the RGB or RGBA image were dragged along the direction indicated. In cartography, the main purpose of **Motion Blur** is as a directional "filter." It also may be used to create artistic effects to give a sense of motion to images.

- **Direction**  A number from zero to 180, showing the direction in degrees around a circle to use for the blur.
- **Amount**  Number of pixels to blur.
- **Preview**  Check to see effect in action.

This command is also available on the Transform Toolbar for images as the **Motion Blur** transform operators:

- **Motion Blur Diagonal 1**  Blurs the image as if moved diagonally on the upper left / lower right axis by the specified number of pixels.
- **Motion Blur Diagonal 2**  Blurs the image as if moved diagonally on the upper right / lower left axis by the specified number of pixels.
- **Motion Blur Horizontal**  Blurs the image as if moved horizontally by the specified number of pixels.
- **Motion Blur Vertical**  Blurs the image as if moved vertically by the specified number of pixels.

However, when used from the transform toolbar the effect is immediate with no preview possible. In the transform toolbar version the parameter specified is used as the amount of pixels to blur.

**Uses**

The obvious artistic usage of **Motion Blur** is to annoy people by making them think their eyes are out of focus:

A more responsible use of **Motion Blur** is to create a blurred version of the image that may then be placed underneath the unaltered image in a map layer. If we take the image shown above and place a cutout of the unblurred monument on top we can give the impression that the monument is moving.
To create this example we made a copy of the bronze image and selected all pixels except the monument. We then deleted those pixels to leave just the monument. This appears in a layer above the blurred image.

**A Cartographic Example**

As much fun as it is to ruin people's eyesight with blur effects, *Motion Blur* does in fact have great utility in vectorization. We use it to extract lines that run in particular directions.

Suppose we have a raster image that contains horizontal and vertical lines as well as many other lines. We want to extract just the horizontal lines.

Applying *Motion Blur* twice with maximum *Amount* setting and a *Direction* of 90 in both cases blurs everything but the horizontal lines. These don't appear to change because their pixels are moved onto each other. Everything else is blurred into various shades of gray.
We can now use Threshold to extract only those lines by setting the threshold range so that everything except the lines is made white.

Had we set the **Direction** to any other value we could have extracted features oriented in any other direction. Since raster images are rarely very accurate it is rare that we have the opportunity to use **Motion Blur** in this way. However, when we can do so the effect is like magic.
Image - Posterize
Converts the RGB or RGBA image to a limited number of colors for a "poster" effect.

Level
Number of color levels allowed in each channel. Very low values (2, 3, or 4) have the most visible effect.

Preview
Check to see effect in action.

This command is also available on the Transform Toolbar for images as the Posterize transform operator. However, when used from the transform toolbar the effect is immediate with no preview possible. In the transform toolbar version the parameter specified is used as the level.

Posterize is best used with small numbers of levels. It divides each channel into intervals of the specified number of levels and then builds colors within those intervals. For three, RGB channels the number of colors used in the image is the cube of the levels specified. For example, specifying 2 levels results in images with eight possible colors (2 R levels x 2 G levels x 2 B levels = 8 possible colors). Therefore, levels much above 6 produce little change.

For good "poster" effects, it’s often advantageous to follow posterize with a Brightness / Contrast adjustment to increase the contrast.
Image - Quantize

Quantize converts colors in RGB, RGBA or grayscale images to the specified number of colors using the desired method.

<table>
<thead>
<tr>
<th>Colors</th>
<th>Number of different colors to be used in the image.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Preview</td>
<td>Check to see effect in action.</td>
</tr>
</tbody>
</table>

For example, using 8 colors with Quantize will transform the sample bronze image using only eight colors to render the image. The Quantize transform will choose and place eight colors to approximate the visual effect of the original colors.

Compare the results of Quantize with 6 colors in the image at above left with the image above right showing the Posterize command applied with a Level of 2, which also results in six colors as well. However, because Posterize uses free selection of color values within intervals it has more different colors. In contrast, Quantize results in an image drawn mostly in greens since these are the predominant tones in this image for visual effect.

A Cartographic Example

Paper maps are often created with the intention of using a limited range of standard colors. The printing process, however, results in small variations in color so that the actual printed map consists of thousands or even millions of colors that fall into several similar classes. When we scan a paper map (perhaps with the intention of using Manifold’s tracing tools to create a drawing) the scanner will create an image that uses a very large number of colors in what appears to our eyes to be a region of identical color.

Manifold’s selection tools allow us to set tolerances so that pixels of similar color can be selected easily. Sometimes, however, we would like to force colors in the image into a more limited number of colors. To do so we can use the Quantize command.
We begin with a scanned RGB image that contains many colors.

Using **Quantize** we can reduce the number of colors to only 6. This forces all the different "violet" colors used in some features to consist of only a single violet color.

We can then select that color using **SHIFT-select touch**, choose **Edit - Select Inverse** and then press **Delete** to delete all colors except the desired violet color.
The image has the **background** layer turned on so that everything except violet looks white; however, we have just created an image where everything that is not violet is a transparent pixel. To clean up the image we can use **Simplify** to eliminate small groups of pixels or single pixels. If desired, we could apply the above procedure to the red colored major roads to extract only those.

We could then combine the two images in a map so that one layer has the violet pixels and the other layer has the red pixels. This map would be a very useful map for tracing major roads shown in the scanned image. (The image above uses slightly different **Simplify** settings for the violet layer than in the previous images).

**Technical Note**

The *Manifold Quantize* transform uses the Wu algorithm to quantize colors with a modification to improve color matching by slightly preferring (weighting) G channel values over R channel values over B channel values. The weighting curves match the sensitivity of the human eye to color frequencies and thus provide a more “natural” look.
Image - Relief
Alters image to provide highlighting as though the RGB or RGBA image contains 3D objects illuminated by light from the side. Choose the direction of apparent lighting and then the degree of 3D relief desired.

This command uses the intensity of pixels as an "elevation" value if no other elevation data source is present. For images created from terrains, Relief will use the actual elevation data from the terrain to compute highlights and shading.

**Direction**  Direction toward which light is shining. "South" means it is shining towards the South.

**Highlights**  Apparent elevation scale to compute brighter, "lighted" points.

**Shadows**  Apparent elevation scale to compute darker, "shaded" points.

**Preview**  Check to see effect in action.

A South-East direction of relief was applied in the example above, so that light is apparently shining from the upper left down towards the lower right.

Moderate amounts of relief will provide useful effects when applied to many aerial photos, especially if the Direction chosen is aligned to the direction of light in the photo. The above example applied a North (upward pointing) direction of light to the image on the right. Since the image already contained visible shadows, a greater degree of Highlights was used than Shadows.
Relief may also be applied to non-geographic images to achieve a wide range of artistic embossing effects. Like all image commands, Relief applies to the entire image unless a selection is in effect, in which case it will apply to the selected pixels only. In the image above we selected a circular group of pixels and then applied Relief to achieve a circular region of embossed appearance.

When applied with restraint, Relief can give "hyper-real" effects to normal photographs, and can bring out hidden detail in geographic images, as seen below:
Image - Relink / Unlink

The Relink and Unlink commands are enabled when the focus is on a window for an image linked from an OGC WMS image server or from a Microsoft TerraServer image server.

- **Relink** - Used to reconnect a linked image to an image server. This command is also available within the linked image's context menu in the project pane. If a linked image is disconnected from an image server this command is used to reconnect it. For example, one might create a .map file that contains a linked image that is linked to an OGC WMS image server using a local URL. If the .map file is moved to another machine the link might not continue to work without adjusting the URL. In that case one can use the Relink command to reconnect the image in the project to the image server.

- **Unlink** - Unlink a linked image to create an image in the project. All data for the image is copied from the image server or cache if caching is enabled (the default) and embedded within the project as would be the case for an ordinary, unlinked image.

Image - Download and Image - Relink / Unlink Compared

An image linked from an image server may be converted to a local image within the project either by using the Image - Unlink command or the Image - Download command. The Unlink command converts the existing linked image to a local image at whatever resolution is currently in use. The Download command may be used to automatically fetch all image tiles at any available resolution to create a local image at that resolution.

Images linked from TerraServer may also be exported to image files. In that case, the exported image will be the same as that which would be obtained by unlinking the TerraServer image.

Note that exporting or unlinking an image linked from TerraServer will only use the data already downloaded from the server and will not attempt to download any more data. It will also only use the data for the most detailed image level. It is usually a good idea to use Image - Download to check how much data has already been downloaded for the most detailed image level prior to exporting or unlinking the image.

Another way to create a local image from a linked image is to open the linked image and then to use the keyboard F6 command or the Tools - Make Image command. The Make Image dialog allows us to create a local image in several different ways from the linked image without unlinking the linked image. For example, we can use this command to create an image of the displayed window or of the entire linked image at a desired number of pixels or scale.

**Very Important**

The Unlink command attempts to build a real image of the same pixel dimensions (width and height) of the linked image. Whatever tiles have been downloaded using the Download command will be used, and will be interpolated to cover those pixel extents. Keep that in mind if you want to unlink a huge linked image.

For example, suppose we create a linked image from a Manifold image server that covers the entire Earth. Images servers will now routinely offer to provide images at 0.3 meter resolution. If we link in such an image from an image server the linked image will be over 120 million x 120 million pixels in size. That's still easy to use within a Manifold project because zooming in or out or panning the image only shows a million or so pixels (1000 x 1000) in whatever viewport we have open, but if we unlink that image we are asking Manifold to create an image that is 120 million x 120 million pixels in size... that's over 50,000 terabytes in size at four bytes per pixel.

One might think that specifying a smaller number of tiles to download via Image - Download will do the trick to keep the data size down, since the Unlink command will use only the tiles downloaded. But suppose we download only those tiles representing, say, 100 kilometer x 100 kilometer resolution: the image we are asking Manifold to create is still 120 million x 120 million pixels in size, at 0.3 meters per pixel. What we are asking Manifold to do will be to take each of those limited number of 100 km x 100 km "pixels" and inflate them to cover the 300,000 x 300,000 pixels of 0.3 meters each within the larger blocks so that each such smaller pixel is the same color.

If what we want to do is to create an unlinked image with a smaller number of pixels, we should specify a lower resolution for the original linked image, choosing some value much greater than the 0.3 meter value for the image server we are using. For example, choosing, say, 5 kilometers results in a much smaller 7500 x 7500 pixel linked image. We can download all the tiles for that and Unlink and still have a relatively workable image.

Image - Simplify

Simplify is a very versatile effect that may be used for both pre-processing of RGB or RGBA images intended for vectorization as well as for purely artistic effects.

- **Level**: Increase to apply more effect (that is, greater simplification).
- **Neighbors**: The number of neighboring pixels to consider for each pixel.
- **Times**: The number of iterations.
- **Preview**: Check to see effect in action.

Simplify works by taking each pixel in the image and examining its neighboring pixels out to a given number. The pixel is then set to a color given by the weighted average of its neighbors. Increasing the **Times** value tells Manifold to repeat the process the given number of iterations. Repeating this process will eventually reach a point where for any given combination of **Level** and **Neighbors** settings there will be a **Times** setting after which no more changes occur.

When applied to the sample bronze image with a high **Level** will result in a pointillist effect.

Applied with a maximum **Level** the figure becomes abstract in its simplification.

A Cartographic Example
We can use the Threshold command to pull features of a given color out of a scanned raster map, such as the above section of a USGS DRG scanned raster map.

Simplify applied with a Neighbors value of 3 gets rid of the scattered dots in the image.
Image - Threshold

Threshold converts each pixel into black, white or unchanged depending on whether the original color value is within the threshold range. Threshold is a very important command that is often used to prepare scanned RGB or RGBA images for vectorization or use as guide layers in the creation of drawings. It can be used with raster data images to set off ranges of values that may then be used for subsequent analysis or as selection masks.

This command is also available on the Transform Toolbar for images as the Threshold, Threshold Black and Threshold White transform operators. However, when used from the transform toolbar the effect is immediate with no preview possible. The parameter in the transform toolbar is used to set the threshold between white and black.

- **[Histogram]** Shows distribution of intensity values. The taller the line, the more pixels have that intensity value.
- **[% number]** The percentage of pixels that are within the threshold range.
- **[Upper edit box]** Beginning of threshold range.
- **[Lower edit box]** End of threshold range.
- **[Left Mouse Click]** Clicking the left mouse button in the histogram sets the left side of the threshold range.
- **[Right Mouse Click]** Clicking the right mouse button in the histogram sets the right side of the threshold range.

**Modify** Choose standard, black or white threshold operation.

- **Both** - All pixels within range are forced white. All others are forced black.
- **Black** - All pixels within range are unchanged. All others are forced black.
- **White** - All pixels within range are forced white. All others are left unchanged.

**Preview** Check to see effect in action.

The two edit boxes set the lower and upper bounds of the threshold range.
Changing the lower box's value from 255 to a lower amount will constrict the threshold range. In the example above, all pixel values with intensity lower than 107 and all those with intensity 141 will be forced black. All those in between will be forced white. The white pixels will be 30% of the pixels in the image.

![Image showing threshold values and resulting image]

The result is an image where all intensities except those middle intensities are black.

**Black and White Options**

Choosing the **Black** option restricts the action of the **Threshold** command to only those pixels that are to be forced black. All other pixels are left unchanged. For example, using the threshold range above all pixels in intensity from 107 to 141 will be left unchanged. All other pixels will be forced black.

The **White** option restricts the action of the **Threshold** command to only those pixels that are to be forced white. In the above example, all pixels from 107 to 141 will be forced white. All other pixels will be left unchanged.

**Use with Color Images**

**Threshold** may be applied to RGB or other multi-channel images. When applied to color images, the histogram shows the intensity level of pixels. For per-channel control of threshold in color images, use the **Threshold Color** command.

We begin with the sample **schloss** image. “Schloss” is German for "castle" or "chateau." The image shows the famous fairy-tale castle, Schloss Neuschwannstein, built by King Ludwig in Bavaria.
The histogram for this image shows that over 40% of the pixels are clustered about a very high intensity. These are obviously the pixels that make up the sky in very high intensity, blue-white colors. We've moved the range controls so that for the most part only the sky pixels will be in range.

The **Both** setting forces all pixels in range to white and all those out of range to black. Since the range ends at 255, there are no pixels above the range. Only darker pixels are below.

Using the **Black** setting changes those pixels that are out of range to black and leaves those pixels in range unmodified. These are the sky pixels, which are left in their original light, blue-white colors.
Using the **White** setting changes those pixels in-range to white and leaves all other pixels unmodified. The above illustration looks similar to the original but on close examination will be seen to have only pure white pixels in the sky where colors used to be light, blue-white tones.

By careful selection of ranges, we can choose only a limited range of intensities to be forced white with all other pixels forced black. For example, the above range will leave only a limited range in white with all intensities above and below the range forced black.

The result is that we have picked out a particular range of intensities in the image. Note how both the very light sky (above the designated range in intensity) as well as the ground and trees (below the range) have both been forced black.

**A Cartographic Example**
Using a scanned image of a map as an example (a USGS DRG map) we can use threshold to suppress details except for the pink colors.

A bit of interactive experimentation shows that the intensity peak selected in the range in the histogram shown above is associated with the many pixels in the image in pink shades, all of which have about the same intensity.

Using **Black** as the modify operator, we force all pixels outside the narrow range to black, leaving only those within the intensity range as pink.
We can move the range to other "bumps" in the histogram to pick out other pixels by intensity ranges.

This range of intensities corresponds to the purple tones.

The next bump in the histogram corresponds to darker red tones.
In all the above examples, we force pixels outside the range to pure black color. This makes it easy to select those pixels using Select Touch and to delete them. Alternately, we could Invert the image to force them to white to make our job of vectorizing a set of lines that much easier. Note the profound simplification of the image in the last example. Note also there is nothing that stops us from using Threshold several times to pick out different "slices" of the image and to then combine them (perhaps after other operations such as Invert) to get exactly the image we want to use for vectorization. Very often the desired result will be reached by combining several commands.

In the above sequence it is tempting to imagine we picked out a particular color to be forced white; however, this is not the case. We have simply picked out a range of intensities. It is often the case in photographic images that particular colors or regions fall into similar intensity ranges so we can exploit this effect sometimes by using intensity as a proxy for color values. For threshold selection by true color values, use the Threshold Color command.

Another way of picking out particular color tones would be to use Select Touch to pick out all the pixels in dark red color. We could then choose Edit - Select Inverse to invert the selection and thus select all pixels except those in dark red color. Next, we could delete the selected pixels or use the Brightness / Contrast control to set the brightness of the selected pixels to zero, which would make them all black. There are often several different methods we can use in Manifold to achieve a desired result. Which method we choose depends on what is most convenient and most accurate at the time.

**Selections**

A reminder: Like all Manifold commands, Threshold will work only on the selected pixels if a selection is present.

In the sequence above, we've selected a "5" shaped region of pixels, applied Threshold and then turned off selection color so the effect can be seen. Cool!
Image - Threshold Color

For RGB or RGBa images, the Threshold Color command is similar to the Threshold command, but works on each individual RGB channel. Please see the Threshold command topic for details on the regular Threshold command.

Threshold Color is a very important command that is often used to prepare scanned images for vectorization or use as guide layers in the creation of drawings. It is also used to pick out colors and ranges of colors for graphics art editing and visual effects. It can be used with raster data images to pick out ranges of values to be used as selection masks.

Although it may be used in a simple interactive way to adjust images based on visual appearances using Preview, in sophisticated hands the Threshold Color dialog is a powerful instrument for choosing regions with specific color characteristics using Boolean combinations of RGB color values.

[Histogram] Shows distribution of intensity values. The taller the line, the more pixels have that intensity value.

[Upper edit box] Beginning of threshold range.

[Lower edit box] End of threshold range.

[Left Mouse Click] Clicking the left mouse button in the histogram sets the left side of the threshold range.

[Right Mouse Click] Clicking the right mouse button in the histogram sets the right side of the threshold range.

Modify Choose standard, black or white threshold operation.

Both - All pixels within range are forced white. All others are forced black.

Black - All pixels within range are unchanged. All others are forced black.

White - All pixels within range are forced white. All others are left unchanged.

Match Choose use of channels in deciding whether to make a pixel black or white (or left unchanged).

All Channels - If pixel is in range in all channels, make it white, otherwise make it black.

Any Channels - If pixel is in range in any channel, make it white, otherwise make it black.

Each Channel - Apply the modify operation to each channel independently. For each pixel, the R, G, and B values will set to 255 if it is in range for that particular channel and to 0 otherwise.

Preview Check to see effect in action.

Threshold Color provides three histogram threshold range panes, one each for the Red, Green and Blue channels. Each channel is considered independently, so the three histograms show the distribution of values for each channel independently of each other. The dialog opens with ranges set so that 50% of the pixels for each channel fall in range.
The histograms above show the RGB values for the sample bronze image. We apply various combinations of Modify and Match settings in the images below:

The default setting of Both forces all pixels within range to white and all pixels out of range to black. Using All channels means that a pixel’s values must be in range in all three R, G and B channels. Note that the brightest regions are forced white and the darkest regions are forced black.
Changing the modify setting to **White** forces pixels in range to white and makes no change (leaves colors unmodified) for this pixels out of range. Note how those pixels forced black in the first image in this sequence retain their original colors.

Using **Black** for the modify setting forces pixels out of range to black and leaves unchanged those pixels in range. Note how the clouds and lighter part of the sky are left unchanged while all the darker pixels are forced black.

Referring once more to the RGB histograms, we can use **Both** for the modify setting so that all pixels will end up either black or white, and now we can change the match setting to **Any Channel**.
If any pixel falls in range within any of its RGB ranges, it will be forced white. Because many pixels in the image are in range in at least one of the three channels, this means that very many pixels will be forced white.

The final case requires the greatest thought to understand. Using Each Channel means that each color range is considered entirely on its own. For each pixel, if the Red value is within range it is set to 255 (that is "forced white"). If it is not in range it is set to 0 ("forced black"). This process is repeated for the Green and Blue values.

Using Each Channel with Both set means that every pixel in the image will be either black, white, red, blue, green, cyan, magenta or yellow because these are all the possible combinations of pixels having all or nothing values in the Red, Green and Blue channels. For information on why this is so see the Images and Channels topic.

The bronze monument ends up yellow because pixels there tend to have lots of red and green (so both the R and G channels are forced full ON), without as much blue. 50% of the high blue pixels are mostly in the sky and clouds, so the default settings for ranges tend to push the B values in the monument to zero. If R and G are 255 and B is zero the result is yellow.

A Cartographic Example

When vectorizing scanned map images into vector drawings, we can often improve the performance of our tools by carefully preparing the scanned image with Manifold image tools before beginning vectorization. Sophisticated use of the Threshold Color command will help us do this. This example shows how Threshold Color can be used to pick out regions of different colors.
For a sample image we will use a USGS DRG format scanned raster map downloaded from the USGS web site. Let's begin by getting rid of all of the black pixels.

To do this, we set up the channel controls with values from 0 to 10 for R, G and B with Modify set to White and a Match for Any Channel. We are telling Manifold to change to white all pixels within the range. The only pixels with such low values in RGB are black or near-black pixels, so this changes all of them to white. We apply this effect so there will be no more black pixels.

To make all pixels white except the bright red ones, we retain the White and Any Channel settings in the Modify and Match controls and choose a range of low values for red and high values for greens and blues. This turns everything white except those pixels with midrange or high values for Red that also have low values for Green and Blue. The result would be to make everything white except the bright red lines. Instead of applying this effect, let's see what we have to do to get the purple lines.
These are more difficult because they include Red color in their pixels as well as Blue and Green. We begin by
setting all of the Red lines to white. Choosing any channel that has the above settings gets rid of bright red while
retaining pink and purple. We apply this effect.

If we now choose high brightness value ranges for all three channels we get rid of the very lightest tones no
matter what their color. The purple colors remain because they are not as bright as the light pink tones.

Notes

When looking at the three RGB histograms it is easy to make the mistake of thinking that a vertical line through
the three histograms will show the R, G and B value for pixels on that line; however, this is a wrong understanding
of the histograms. The histograms simply show the distribution of pixels by the total number of pixels at each R,
G and B level. The histograms do not mean that these are the same pixels at each level even though that might
often be the case. Certain color tones will often have similar values in R, G and B. For example, white clouds in
a sky will show peaks in all three histograms because many pixels in those clouds will simultaneously have high
values in all three channels.

To get the same pixel at each level, we need to average the R, G and B values into a combined intensity, which is
how the regular Threshold command works. In many instances we can use the intensity as a proxy to pick out
specific color shades. See the Threshold command topic for an example.
Image - Tile
Divides an RGB or RGBA image into tiles of given X and Y extent and then averages pixel values within the tiles to derive a single color that is then applied to the entire tile. This is used for aggregating and interpolating raster data images into larger tiles and for creating "pixelated" artistic effects.

This command is also available on the Transform Toolbar for images as the Tile transform operator. However, when used from the transform toolbar the effect is immediate with no preview possible. The parameter for Tile in the transform toolbar is used for both the X and Y pixel tile size.

- **X Tile**: Size of tiles in pixels in horizontal direction.
- **Y Tile**: Size of tiles in pixels in vertical direction.
- **Use same X and Y**: When checked, any change in X or Y the other value as well so that X and Y values are always the same.
- **Preserve Colors**: If checked, will use a median computation to derive the color to be used for the tile from only those colors that already exist in the image.
- **Preview**: Check to see effect in action.

If we begin with the sample bronze image, using a value of 10 for both X and Y converts the image into tiles that are 10 pixels square where each tile is a single, solid color.

Using different values for X and Y results in rectangular tiles. The above image was created with X value of 16 and Y value of 4. The resulting tiles are sixteen pixels wide and four pixels high.
Using an X of 1 pixel and a Y of 16 results in an interesting artistic effect.

Preserve Colors Checkbox

The Preserve Colors checkbox controls how Tile determines what color to use for the tile. If this box is not checked, Tile will average the RGB values for all pixels within the tile to determine what RGB values represent an arithmetic average. This may pick out a new color that is not yet used within the image. When the Preserve Colors checkbox is checked, Tile will use a median computation to find the color already used within the image that is a best fit to the desired, interpolated color to use for the tile.

We use the Preserve Colors checkbox if this image was converted from a limited palette image and we do not want any new colors introduced into the image.
Image - Resize
Change the horizontal and/or vertical size of an RGB or RGBA image using bicubic, bilinear or nearest neighbor interpolation.

<table>
<thead>
<tr>
<th>Method</th>
<th>Bicubic</th>
</tr>
</thead>
<tbody>
<tr>
<td>Width</td>
<td>186 pixels</td>
</tr>
<tr>
<td>Height</td>
<td>160 pixels</td>
</tr>
<tr>
<td>Constrain Proportions</td>
<td>✔</td>
</tr>
</tbody>
</table>

Method: Choose the interpolation method to be used to recompute new pixel values as pixels are added or removed to achieve the new size.

Width: Width of the resized image in pixels.

Height: Height of the resized image in pixels.

Constrain Proportions: Checking this box will cause any change in Width or Height to automatically update the other parameter so that the width to height proportion is kept the same.

The size readout at the bottom of the dialog gives the size of the image in kilobytes at the specified width and height.

The Method box chooses the mathematical technique used to interpolate the existing pixels into a greater or lesser number of pixels as the image changes size. Different methods will at times work better or worse depending on the image content. Choose from Bicubic, Bilinear and Nearest Neighbor. The default Bicubic method works best with most images.
The Convert To command converts images into different methods of handling color: RGBA, RGB, Grayscale and Palette images. Convert To changes the image data permanently. The Convert To dialog will also report the estimated size of the resulting image. The Convert To command may also be used to convert linked images into local images within the project.

**Image - Convert To**

Target Desired type of image: Compressed, Grayscale, RGB, RGBA or Palette.

Palette Choose one of the preset palettes for a specific usage, when converting to a Palette image.

Metric Method for computing proximity of colors to each other when judging if colors are close to each other in the color cube. Displayed when converting to palette images. Use Euclidean: the other settings are rarely used metrics provided for expert use in special situations.

Colors The number of colors to use to create the image. Displayed when converting to palette images.

Dither Check to use dithering. Displayed when converting to palette images.

Ratio Compression ratio. Displayed when converting to compressed images. Larger Ratio numbers will result in greater compression at the cost of lesser image quality. A ratio of 10 will create a compressed image that is one-tenth the size of the original image.

Save result as new component Instead of converting the same image component, places the converted image into a new component.
