The Target box will contain only those choices other than the method currently employed for the image. RGB images, for example, will only have Palette and Grayscale appear as choices.

See the Dither topic for information on dithering.

**Palettes**

Adaptive Sample colors appearing most frequently in the image and use these to choose a best fit to the given number of colors from the entire RGB space.

Linear Choose colors that are evenly spaced in the RGB cube space for the given number of colors.

Photoshop Use the 90-color Photoshop swatches palette. Handy for many restricted-color graphics arts images.

System Use the 256-color Microsoft Windows system palette.

System (Mac) Use the 256-color Apple Mac system palette.

VisiBone 2 Use the VisiBone web designers palette.

Web Use standard 216-color palette included by default in all web browsers.

Palettes used by other applications and systems are provides so that images destined for those systems can be created using an exact match of palettes.

Grayscale and palette images may be converted into RGB images without any loss of color values. Thus, one may take a grayscale image, convert it into RGB, and then convert it back into grayscale without any loss of color data.
The reverse is not true: when converting RGB images into grayscale or palette images there will be a permanent loss of color information as the RGB color information is interpolated down into a much smaller set of tones that are available in grayscale or palette images.

RGBA are RGB images with an extra channel that allows setting a percentage transparency for each pixel. This is called an "alpha" channel. RGBA images are used when many smaller images are stacked together in a map to achieve photocomposition effects as is done with professional image editors such as Adobe PhotoShop. See the Layers topic for an example.

Compressed Images

Compressed images are decompressed when converted into other image types. Since compressed images are often very, very large be careful to consider the resulting size of image when converting into other image types. Keep in mind that compressed images also use a sophisticated display algorithm to more rapidly display the compressed data. When decompressed and converted into other image types the speed of redisplay available with a compressed image will no longer be available.

When converting images into Compressed form, although the visual appearance of the image will be almost exactly the same (or even may appear to be enhanced) the actual information content of the image will be reduced. The high-speed compression algorithms used are normally lossy algorithms based upon wavelet compression or similar compression strategies. Although they preserve or enhance visual appearance, the specific pixel values will change.

Consider the RGB image seen at high zoom level above. We have zoomed in so that individual pixels are visible. The scene illustrated is the Northern part of Baja California in Mexico and the Sea of Cortez.

After conversion to a compressed image, the scene at the same zoom level appears above. Note that individual pixels are no longer discernable because the compression technology used synthesizes a scene using full screen resolution to utilize however many pixels are available in the computer monitor's display.

Although the scene looks very realistic (considering the high zoom into what was originally a low-resolution image), it is very important for scientific purposes to understand that the information content in the compressed
image is less than that of the original. The compressed image only looks good visually because a clever decompression-on-the-fly algorithm was used to synthesize a visually appealing image from a smaller number of bytes.

When converting to other image types a compressed image can expand into a dramatically larger image in terms of storage space required. Pay careful attention to the estimated size reported by the Convert To dialog for the resulting image to avoid creating unexpectedly large images.

**Tech Tip**

Read only images (for example, from an Enterprise server if Enterprise Edition is being used) can be converted to other types of images if the **Save result as new component** box is checked.

Attempting to convert an image to a compressed format using **Convert To** will display any error messages returned by the ECW / JPEG2000 compression code should the conversion fail.

**Table Menu**

**Table - Add Active Column**

See the Active Columns topic. The **Edit Active Column** dialog is the same dialog that is titled differently and used when editing an existing Active Column.
Table - Add Rank Column

See the Rank Columns, Decision Support System and Add Rank Column Dialog topics.
Table - Address - Geocode

The Geocode command takes an address in standard form, finds it in the Manifold Geocoding Data product and then produces latitude and longitude values for the location of the address. Addresses to be geocoded must include the four standard Address, City, State and Zip fields.

Records that cannot be located within the error level specified by the Fail on parameter will be reported in an Unmatched Records dialog to allow editing and selection of proposed matches the system determines may be the correct locations. If a particular address cannot be located on a street, the system will report "Building not found" and will offer a match to the address. Choosing that match will choose a location for the address that is at the midpoint of the street segment for the street of that name.

Records that cannot be geocoded at all, even after manual intervention, will have zero values for latitude and longitude. When the table is copied and pasted as a drawing these records will be ignored if the Skip zero latitude / longitude records option is checked (the default setting) in the Paste As Drawing dialog.

If an address cannot be found in the available street address ranges for a specific street the command will choose a point near the middle of the street segment.

Geocode Addresses Dialog Controls

- **generate ... using** Specify the columns to be used for Longitude and Latitude, Status and Match type fields, and which columns in the table should be used for the standardized Address, City, State, and Zip fields.
- **Longitude** Table column to be used for the longitude of geocoded record. Contains 0 if the record was not geocoded. Use [New Column] to automatically create a new column called Longitude.
- **Latitude** Table column to be used for the latitude of geocoded record. Contains 0 if the record was not geocoded. Use [New Column] to automatically create a new column called Latitude.
- **Status** If desired, add a column that reports the status of a particular record after processing. [None] does not report status, [New Column] will add a new column to the table called Status.
- **Match type** If desired, add a column that reports the geocoding match type of a particular record after processing. [None] does not report match type, [New Column] will add a new column to the table called Match type.
- **Fail on** Criterion to be used to declare a particular record to be unmatched.
- **Offset Locations by** Offset the location for each geocoded record by the given number of units from the street line, to the left or right side of the street based on whether the address was found in the left or right range.
- **Skip completed records** Do not process records that already have values in the designated Address, City, State and Zip fields.

Fail on Options

- **any error** Does not process record unless it is a perfect match in all fields. Equivalent to setting an "unknown building" error.
- **unknown street name, possible misspelling** Matches to Zip and City and does not process record unless the street name is an exact match.
- **unknown street name,** Matches to Zip and City, and attempts to match to similar
no similar names  street names if an exact match to the street name cannot be found. Uses "Soundex" and similar algorithms to attempt to find the right street in case of a street name misspelling. This is the default setting.

unknown zip  Do not process record if the zip code cannot be found.

critical error  Stop processing only on problems with an incomplete geocoding database or on hardware failure.

Match type Values

When reporting the status of a record's processing in a Match Type field the following values are used, listed in order from most precise to least precise:

building  The zip code, street name and building number were used to identify a location at the building's number.

street  The zip code and acceptable street name were found but not the building's number so the location has been placed at the center of the bounding box for the street.

zip  Only a zip code was used so the location has been placed at the center of the bounding box for the zip code.

city  Only the city name was used so the location has been placed at the center of the bounding box for the zip code.

((empty string))  The record could not be geocoded and values of 0 have been written into both Latitude and Longitude.

Selections

Both the Standardize and the Geocode commands are auto-scoped: if a selection is present in the table they will operate only on the selected records.

Table - Address - Standardize
No Data
Table - Design

Launches design dialog to change the structure of a table. In tables, columns are fields. We use the words "field" and "column" interchangeably. The Design dialog is resizable.

This dialog may be used to alter the structure of linked tables as well as local tables. It is therefore a popular way of administering database tables even in databases outside of Manifold. To do so, use the Database Console to open the data source and link a desired table into the Manifold project. Next, open the linked table and use the Design dialog to alter the structure.

- **New Column** - Add a new column (field). By default, columns are added as 32 bit integers.
- **Delete** - Delete highlighted column.
- **Move to Top** - Move the highlighted column to the top of the column stack. This displays it as the leftmost column in a table.
- **Move Up** - Move the highlighted column up one position in the column stack. This displays it one column position to the left in a table.
- **Move Down** - Move the highlighted column down one position in the column stack. This displays it one column position to the right in a table.
- **Move to Bottom** - Move the highlighted column to the bottom of the column stack. This displays it as the rightmost column in a table.
- **Edit Values** - Reserved for future expansion.
- **View Default Values** - Show a column in the design pane for default values field.
- **View Types** - Show a column in the design pane for database types for each field.
- **View Transfer Rules** - Show transfer rules for each column. The transfer rules may be adjusted by double-clicking into a rule.
- **View Extended Properties** - Enabled for linked tables. Show extended properties in a "Unique" column. A typical extended property is to note which field is the primary key.

To add a new field to a table:

1. Open the table.
2. Choose Table - Design
3. Click on the Add Field button. A new field appears in the design pane.
4. Double click into the Name field and change the name as desired.
5. Click in the View Types button. Type and Size columns appear in the design pane.
6. Double click into the Type column for the new field and change the database type as desired for this field.
7. Double click into the Size column for the new field and specify the size as desired. Some defaults, such as a size of 1 for 8-bit integers, cannot be changed.
8. Press OK.

When adding a new field to a linked table, the Unique column will be enabled and a combo box will allow specifying the value of the Unique column to primary key, unique or blank. This column is made visible by pushing in the View Extended Properties button in the Design dialog's toolbar.
Default Values

Some database operations and record-creation operations benefit from knowing what a default value for a particular field is supposed to be.

To specify defaults for any field, first click the View Default Values button to show a Default Value column in the design pane. Double click into the Default Value cell for a field to specify a default value that should be used.

See Also

Database Console
Table - Relations
**Table - Relations**

Launches relations dialog to create and manage relations between two tables. **Relations** are connections between two tables that allow one table to show columns from another table. A relation between tables uses a key field with unique values common to both tables to connect the two tables. This allows data that appears in one table to also appear in another table without having to physically duplicate the data. The **Relations** dialog is resizable.

**To form a relation between two tables**

1. Open the table that is to display the additional fields and click on **Table - Relations**.
2. Click on the **New Relation** button. This launches the **Add Relation** dialog.
3. In the **Add Relation** dialog, choose another table from the list box.
4. In the **Add Relation** dialog, click on one field for each table that will be used to match records and press **OK**.
5. Back in the **Relations** dialog, check the desired columns from the other table. Press **OK**.

Columns that are "borrowed" from another table will appear in the table with yellow background color to indicate they are imported. They may be used like any other column, for example, for sorting, filtering or within formulas or thematic formatting. Tables may have more than one relation with more than one other table.

Columns that are included from other tables may not be used as a key field to form a new relation. Columns can only be linked through one relation. They cannot be passed on in turn through yet another relation. For example, if table A has a relation with table B so that columns B1 and B2 appear in table A, table C cannot form a relation with table A and "borrow" columns B1 and B2 from table A. To include columns B1 and B2 in table C, table C must form a relation directly with table B.

**Relations Dialog Commands**

- **New Relation** - Add a new relation.
- **Delete** - Delete highlighted relation.
- **Include All** - Show all columns from the related table in this table. Check all checkboxes.
- **Include None** - Do not show any columns from the related table in this table. Uncheck all checkboxes.
- **Include Inverse** - Uncheck all checked columns and check all unchecked columns. A fast way to show all but one column: click **Include None**, check the one column not desired and then click **Include Inverse**.
- **Properties** - Edit the highlighted relation.

**Example**

Relations are used to add columns to tables from other tables.
Suppose we have a Customers table with a CustomerID field and a ContactName field.

Suppose also we have an Orders table with OrderID, CustomerID and an OrderDate field.

We would like to create a relation that shows in the Customers table the OrderID and OrderDate columns so that for each customer we can see all orders for that customer as well as the date of order. To do this, we open the Customers table and choose Table - Relations.

In the Table Relations dialog we click the New Relation button to add a relation. This opens the Add Relation dialog.

In this dialog we choose the Orders table in the list box and then highlight CustomerID as the linking field in both the Customers table (the left pane) as well as in the Orders table (the right pane, under the list box showing the Orders table). Note that we could have used any two fields that contain matching values even if they are named differently. However, as a matter of sensible database organization it makes sense to give the same name to the field used to save customer identification in all tables. We press OK.
The result back in the Relations pane is that we have a new relation listed as CustomerID: Orders.CustomerID. This is a shorthand way of saying that this relation is determined by matching values in the CustomerID field in this table to the CustomerID field in the Orders table.

We check the fields (columns) we would like to include from the Orders table and press OK.

The result in the Customers table window is that two new columns appear, the contents of which are taken from the Orders table. These contents are shown in yellow, which is a generic background color used to indicate values that are computed or otherwise derived.

Notes

A table may have more than one relation. For example Table A might include two columns, B1 and B2, by way of a relation with Table B and Table A might also simultaneously include one more column, C1, by way of a relation with Table C.

Relations can exist between any tables that exist in the project. In particular, a drawing’s table can have a relation with another table.

Relations can exist between tables that are imported into a project and tables that are linked into a project.
When including fields from tables that are linked into a project, keep in mind that tables linked into a project may be provided by files or OLE DB providers that might be participating in multi-user sessions with other programs. That's usually the objective of including such external tables, of course, but one should not be surprised if data in columns that are included from external tables appears to change without user intervention.
Table - Relink / Unlink

The Relink and Unlink commands are enabled when a linked table has the focus.

- **Relink** - Used to reconnect a linked table to a data source. This command is also available within the table's context menu in the project pane. If a linked table is disconnected from a data source this command is used to reconnect it. For example, one might create a .map file that contains a linked table that is linked to an Access .mdb file. If the .map file and the .mdb file are moved to another machine the link might not continue to work. In that case one can use the Relink command to reconnect the table in the project to the .mdb file.

- **Unlink** - Unlink a linked table to create a table in the project. All data for the table is copied from the data source and embedded within the project as would be the case for an ordinary, unlinked table.

See Also

Importing and Linking Tables
**Table - Match**

The Table - Match command provides spatial geocoding within Manifold System. Match can be used to geocode tables by matching locations to drawings of postal codes, provinces, regions, counties or other geographic entities. Such drawings/maps are much more frequently available in international settings than are detailed data sets necessary for address geocoding. In addition, Match can be used to spatially geocode tables of all types using drawings as a guide. For example a table of well drilling information can be geocoded using a drawing of well locations as a guide.

**Controls**

- **Match** - Choose a drawing to which the table should be spatially matched.
- **Move to Top** - Move the highlighted field to the top of the field list. This gives it the highest priority in matching.
- **Move Up** - Move the highlighted field up one position in the field list.
- **Move Down** - Move the highlighted field down one position in the field list.
- **Move to Bottom** - Move the highlighted field to the bottom of the field list. This gives it the lowest priority in matching.
- **Use Case** - Consider upper or lower case when matching text values in fields. When pressed, "nAme" will not match "Name" or "name".
- **Use Side Whitespace** - Consider space characters occurring before or after text strings. If pressed, " 89701" will not match "89701" (with two spaces before the 8).
- **Use Interior Whitespace** - Consider space characters occurring within text strings. If pressed, "8 9 7 0 1" will not match "89 701".
- **Match All** - If pressed, requires a match to all fields.

**Column / Match To Pane** - Choose fields that must be matched to guide a spatial match.

- **X** - Field name to save longitude / x data. Suggested name: "Longitude".
- **Y** - Field name to save latitude / y data. Suggested name: "Latitude".

**Latitude / Longitude coordinates** - Write location in decimal degrees latitude and longitude.

**Match** is easy to use. If we have a database table that has one field in common with a drawing, we can use the drawing to geocode the table.

To spatially geocode a table using Match:

1. Open the table.
2. Choose Table - Match - Drawing
3. In the Match Drawing dialog choose the name of the drawing to serve as a spatial guide.
4. Choose the fields in the table that are to be matched to fields in the drawing.
5. Press control options as desired for matching text values.
6. In the X and Y boxes specify a name to use for the longitude field and latitude field.
7. Verify the Latitude / Longitude coordinates box is checked and press OK.

Each record in the table will be compared to all objects in the drawing for the specified fields. If the record matches field values for an object in the drawing the latitude and longitude of that object’s centroid will be written into the records latitude and longitude fields.

If only one field is specified, the records in the table will be geocoded by matching objects against that single field. If two or more fields are specified, Manifold will try to match in order.

See Also

See the Spatial Geocoding with Match topic for an example.

Script Menu

The Script menu appears in the main menu whenever a script window has the focus. It provides a menu of commands used to develop and debug scripts.

- **Open Form**: Open the form associated with this script.
- **Open Table**: Open the table associated with this script.
- **Run**: Run the script
- **Run under Debugger**: Run the script using the debugger. Available only if the script is written in an ActiveX language that supports the Microsoft debugging interface and if a Manifold edition that includes the Manifold debugger is installed.
- **Pause**: Pause running the script.
- **Stop**: Stop running the script.
- **Step Into**: Step into a function.
- **Step Out**: Step out of a function.
- **Step Over**: Step over a function.
- **Language**: Choose a scripting language.
- **References**: Available whenever a script window using a .NET language is opened. Allows specification of external .NET modules to which the script may refer.
- **Compile to DLL**: Available whenever a script window using a .NET language is opened.

In addition, the script Properties context menu pops up when we right click on a script in the project pane and choose Properties. This menu allows us to check the Run in separate thread property. Running a script in a separate thread allows using advanced scripting techniques such as scripting the user interface, but might be slightly slower in some cases. By default, the option is turned off.

See Also

Debugger
Script - Compile to DLL
Enabled when a script window using a .NET language is opened. This command allows compilation of the .NET script into a DLL.

When a script using a .NET language is created in Manifold it will be automatically compiled when it is run. Using the Compile to DLL command allows us to compile the script into a DLL before it is run. A DLL compiled this way will be identical to a DLL compiled with Microsoft Visual Studio and will contain the code for .NET entities defined in the script component.

One might want to compile a .NET script into a DLL for several reasons:
- To share the code between scripts.
- To expose code originally written as a Manifold script to other programs.
- To reduce the time it takes to launch a script by eliminating the need to compile it before running.

To compile a .dll from a .NET language script:

1. Open the .NET language script.
2. Choose Script - Compile to DLL.
3. In the Save As dialog, browse to a folder location and provide a filename. Press Save.
4. Any errors during compilation will be logged in the Errors pane.

The Errors pane displays the description, module, line and line position of any errors that occur during the compilation phase of running a .NET script. Highlighting an error in the Errors pane and clicking Go To (or, simply double-clicking the error) will open the relevant script component and place the cursor at the location of the error.

View - Panes - Errors
Script - Language

Manifold supports programming in scripting languages installed in your computer. The Script - Language dialog allows choice of which scripting language is used. VBscript (Microsoft Visual Basic Scripting Edition) is the default choice. Any ActiveX or .NET scripting language installed in your Windows system may be used. However, only VBscript may be programmed using Manifold's drag and drop, forms based programming facilities. Other languages must be programmed (in the usual way) using text interfaces.

Choose a scripting language from the Engine dialog. ActiveX and .NET languages installed in your system will be available in this dialog. The language selected will thereafter be used for that script. By default, since Manifold requires installation of IE both VBscript and Jscript are always available. Free downloads from numerous sites provide various other languages as ActiveX scripting engines. For example, one can download ActivePython or ActivePerl from the www.activestate.com site.

The dialog reports the scripting language, the version and the path for ActiveX scripting engines. When a script is read-only (that is linked from an Enterprise server if Enterprise Edition is used), this dialog will still report the language used by the script even though the language may not be changed for a read-only script.

The project pane status bar will also report the language used by a script component when the script is highlighted in the project pane.

.NET Languages

.NET languages like C#, Jscript.NET and VB.NET may also be used within Manifold scripts. If a .NET language is used, the Script - References command will be enabled, allowing use of external .NET modules within a script.

See Also

Please see the Programming Manifold topic for a discussion of scripting languages in Manifold.

See the Scripts topic for convenient keyboard shortcuts when working with scripts.
**Script - References**

The **Script - References** dialog is available whenever a script window using a .NET language as the Script - Language is opened. The dialog allows specification of external .NET modules to which the script may refer.

For example, one can refer to `System.Windows.Forms.dll` and have a script display a form. The resulting script can then be shared on an Enterprise server (if Enterprise Edition is installed) and reused in other projects, not something that can be done with Forms components.

When a script is read-only (that is linked from an Enterprise server if Enterprise Edition is used), this dialog will report the references used by the script.

- **New** - Add a new module.
- **Delete** - Delete highlighted module.
- **Move to Top** - Move the highlighted module to the top of the module stack.
- **Move Up** - Move the highlighted module up one position in the module stack.
- **Move Down** - Move the highlighted module down one position in the module stack.
- **Move to Bottom** - Move the highlighted module to the bottom of the module stack.

When adding a new module, keep in mind that system modules such as `System.Data`, `System.Windows.Forms` or `System.Xml` are usually located in

```
C:\Windows\Microsoft.NET\Framework\vXXX
```

...where **XXX** is the version of the .NET framework installed.

**Script - Language**

**Surface Menu**

**Surface Menu**

The **Surface** menu appears in the main menu whenever a surface window has the focus or a surface layer in a map is the active layer. Commands listed below will appear either under the main **Surface** menu or under submenus such as **Adjust** or **Effects**.

- **Invert** - Invert pixel height value. Creates a topographic negative so that heights become low regions and vice versa.
- **Threshold** - Forces height pixels to maximum, minimum or unchanged based on a histogram.
- **Posterize** - Convert surface to a limited number of height values. Height values are chosen to be evenly spread throughout the total range of heights for the number of levels specified.
- **Filter** - Applies convolution filters, either custom filters or a choice from numerous presets.
- **Noise** - Add random height values.
<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Tile</strong></td>
<td>Convert surface into rectangular tiled regions of appropriate height.</td>
</tr>
<tr>
<td><strong>Quantize</strong></td>
<td>Convert surface to the specified number of height values using the most frequently occurring heights.</td>
</tr>
<tr>
<td><strong>Resize</strong></td>
<td>Change the number of pixels in the surface using desired interpolation method.</td>
</tr>
<tr>
<td><strong>Convert To</strong></td>
<td>Convert the numeric types used for height information in the surface.</td>
</tr>
<tr>
<td><strong>Contours</strong></td>
<td>Create contours using this surface.</td>
</tr>
</tbody>
</table>
**Surface - Invert**

Invert pixel height value. Creates a topographic negative so that heights become low regions and vice versa.

- **Center**  The percentile about which inversion should be calculated. The illustration above shows a 50 percent inversion, which evenly flips highs and lows.

- **Preview**  Check to see the modification in action.
Surface - Threshold
Forces height pixels to maximum, minimum or unchanged based on a histogram. All height values below the lower range or above the upper range will be set to the lowest value (or left unaltered). All height values within the range can be set to the highest value (or left unaltered).

The above threshold conversion was done modifying all the lower values ("black") below 500 to the value 500 and thus the lowest color in the palette.

All of the values above 500 were left unchanged.

---

Values
Choose the minimum and maximum values for the modification range. The modification range is shown in white (lighter color) in the histogram with values outside of the range shown in black (darker color).

[Histogram Display] Left click to set the lower range and right click to set the upper range. The numeric readout shows the percentage of height pixels falling within the modification range.

Modify
Choose Both to modify values within as well as outside of the specified range. Choose Black to modify only those values outside the range. Choose White to modify only those values inside the range.

Preview
Check to see the modification in action.

The Threshold command can be used to cut contours out of a surface within a desired range.
For example, the dialog above has been set up to modify all pixels outside the specified range.

The result shows a "flat" terrain of low height everywhere except the narrow band of elevations within the specified range that are left unmodified.
**Surface - Posterize**

Convert surface to a limited number of height values. Height values are chosen to be evenly spread throughout the total range of heights for the number of levels specified.

**Levels**  Number of height intervals into which the total height range of the surface should be divided.

**Preview**  Check to see the modification in action.

For a surface ranging from 0 to 100 meters choosing a **Level** of 10 will resample the surface into only ten different height values every ten meters. The screen shot above used 8 levels.
Surface - Filter

The Filter command exposes the internal functioning of the convolution filter operators in the Transform toolbar for surfaces and allows us to use custom commands using convolution filters. Most users will apply the commands in the Transform toolbar without ever examining their matrix values in the Filter command. However, for those users who are so inclined, the Filter command provides an "open door" to altering existing filters and creating new ones.

Many computational effects for images and surfaces are created through a mathematical process called convolution. When applied to surfaces, the heights of pixels are recomputed based on the values of surrounding pixels. The rules for how each pixel's height value should be computed are given by a matrix of numbers, where the central number gives the height of the pixel and the other numbers set forth how values from surrounding pixels should be multiplied into the convolution. The illustration above shows the effect of the Difference West filter.

Choosing different numbers for the convolution matrix results in a very wide range of visual effects such as sharpening, blur and so on. Manifold provides a 5 x 5 matrix, where each pixel may be adjusted based on reference to 24 surrounding pixels. This convolution matrix will be applied in turn to each pixel in the image.

[List Box] Choose a preset filter from a list. Choose Custom to create a new filter.

Apply Load the convolution matrix with the numbers for the filter currently shown in the preset box.
Save As… Save current convolution matrix as a preset filter.
Delete Delete previously-saved preset filter or disable factory preset.
Preview Check to see effect in action.

The list box at the top of the dialog allows choice of a filter from many preset filters. Because there are many presets and because at times very large surfaces may be manipulated in Manifold, choosing a preset does not apply that preset's convolution matrix numbers to the matrix until the Apply button is pressed. This makes it possible to browse the presets without applying their convolution matrix to the main surface regardless of whether the Preview box is checked or not.

The Filter dialog has a choice box at the top for preset filter effects.

Applying a Custom Filter

1. Choose a starting preset in the choice box.
2. Enter a value for the center box. This is the height multiplication value for the target pixel. Most values used are quite small, almost always less than 20.
3. The boxes surrounding the center box represent pixels surrounding the target pixel. In each box, enter the convolution multiplication value to use for that pixel. For example, to multiply the height value by 3 of the pixel immediately to the left of the target pixel, place the number 3 in the box immediately to the left of the center box.
4. Not all boxes need to be filled. Boxes left empty will cause the pixels they represent not to be used for the convolution calculation.
5. Enter the value for scale to be used. Convolution works by multiplying the height values of pixels used by the number in their box and then adding up the result. This result is divided by the scale number. Larger scale numbers result in less overall height.
6. Enter the value of offset, if any, to be used. The offset number is added to the height values computed as a result of the convolution divided by the scale. Positive numbers for offset increase overall height. Negative numbers decrease overall height.

See Also

Convolution filters for surfaces are very similar to convolution filters for images. See the Image - Filter topic for examples and tips for continuing education.
**Surface - Noise**

Add random height values. A rarely used command mainly of interest for simulations and creation of sample surfaces for testing surface processing scripts.

<table>
<thead>
<tr>
<th>Amount</th>
<th>Amount of random heights to add as a percentage of the total. The example above uses 6 percent.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Preview</td>
<td>Check to see the modification in action.</td>
</tr>
</tbody>
</table>
**Surface - Tile**

Divides surface into square tiles of given extent and then averages pixel values within the tiles. This is used for aggregating and interpolating surfaces into larger tiles and for creating "pixelated" artistic effects. The tile transform operator is frequently used for this function. The tile command in the Surface menu exposes separate controls for X and Y tile dimension.

![Tile Surface Example](image)

- **X Tile**  
  Width (East - West extent) of tiles in pixels.

- **Y Tile**  
  Height (North - South extent) of tiles in pixels.

- **Use same X and Y**  
  Changes in either X Tile or Y Tile will update the other parameter. The illustration above uses 15 for both X Tile and Y Tile.

- **Preserve Values**  
  Use the closest existing value to the average within a tile.

- **Preview**  
  Check to see the modification in action.

**See Also**

See the Transform - Surface - Tile Operators topic for some nice terrain screenshots of tiled surfaces.
Surface - Transform

The Surface - Transform menu selection is enabled when the optional Surface Tools extension has been installed and the focus is on a surface window or on a surface layer in a map window. If you have not activated the Surface Tools extension with a valid Surface Tools serial number you will not be able to use the Surface - Transform command.

Launching the Transform command in the Surface menu launches the Transform dialog.

- **Scope**: The pixels in the surface that will be affected by the formula. Allows choice of [All Pixels], [Invisible Pixels] or any selection or saved selection made in the surface.
- **Surfaces**: A list of all surfaces in the project. Double-click on a surface name to add it to the Formula pane at the current cursor position.
- **Formula**: Allows entry of any formula that will transform the surface as desired. For details on formulas, operators and examples see the Transforming Surfaces topic.
- **Save result as new component**: If not checked (the default) the formula operates on the surface that had the focus when the dialog was launched, if the surface is not read-only. If checked, the system will first make a copy of the context surface and will then execute the formula in the context of that copy.
- **OK**: Execute the formula and make any changes directed to the surface.
- **Cancel**: Exit the dialog without making any changes.

The Scope specifies the pixels that will be affected by the transformation, and can be [All Pixels], [Invisible Pixels] or any selection or saved selection made in the surface. Formulas can contain numbers, names of surfaces (names of surfaces must be enclosed in square brackets []) if the name contains a space character, arithmetic operations and functions. Formulas are case insensitive. When we press the OK button, each pixel in the surface in the scope will be replaced with the value of the formula for that pixel.

If we would like to preserve the original surface unmodified we can check the Save result as new component box and the system will create a new surface (a copy of the surface which had the focus when the dialog was launched) and put the results of the formula there. The Save result as new component also allows us to...
surface transformations on a surface that is a read-only component, such as perhaps a surface that has been linked into a project from an Enterprise storage using the Enterprise Edition of Manifold System.

Transform Dialog Functions and Operators
**Surface - Quantize**

Convert surface to the specified number of height values using the most frequently occurring heights.

<table>
<thead>
<tr>
<th>Values</th>
<th>Number of height values to be selected into which the total height range of the surface should be divided.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Preview</td>
<td>Check to see the modification in action.</td>
</tr>
</tbody>
</table>

For a surface ranging from 0 to 100 meters choosing a **Level** of 8 will resample the surface to find eight height values that most closely approximate the range of height values in the original surface.

The screenshot above was created with 8 as the **Values** number. Because a relatively small number of pixels used the very highest heights the region of greater heights is approximately with a single height shown in green color. The great majority of the surface (not seen in the above cropped views) had height values in the ranges approximated by the magenta and blue shades so these were used for the other seven values.
Surface - Resize

Change the number of pixels in the surface using desired interpolation method.

<table>
<thead>
<tr>
<th>Method</th>
<th>Choose the interpolation method to be used to re-compute new pixel values as pixels are added or removed to achieve the new size.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Width</td>
<td>Width of the resized surface in pixels.</td>
</tr>
<tr>
<td>Height</td>
<td>Height of the resized surface in pixels.</td>
</tr>
<tr>
<td>Constrain Proportions</td>
<td>Checking this box will cause any change in Width or Height to automatically update the other parameter so that the width to height proportion is kept the same.</td>
</tr>
</tbody>
</table>

The size readout at the bottom of the dialog gives the size of the surface in kilobytes at the specified width and height.

The **Method** box chooses the mathematical technique used to interpolate the existing pixels into a greater or lesser number of pixels as the surface changes size. Different methods will at times work better or worse depending on the surface content. Choose from **Bicubic**, **Bilinear** and **Nearest Neighbor**. The default **Bicubic** method works best with most surfaces.

The screenshot above was created by deleting the least significant digit in the **Width** and **Height** values of the original surface, thus reducing the size of the surface by a factor of ten. Note that "size" in this case means the number of pixels used to represent the surface. A georegistered surface will continue to cover the same size on Earth after "resizing". If the surface is made one-tenth the height and width of the original, each individual pixel will simply cover the ground area that one hundred pixels formerly covered.
**Surface - Convert To**

Convert the numeric types used for height information in the surface.

<table>
<thead>
<tr>
<th>Type</th>
<th>Choose the numeric type to be used.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Autoscale Values</strong></td>
<td>If checked, will recompute the heights to fit in a proportional dispersion through the range of the selected type. For example, if converting from floating point to an integer type allowing -128 to +127 the height values will be rescaled to fit proportionally through this range.</td>
</tr>
<tr>
<td><strong>Embed missing values</strong></td>
<td>Enabled when Autoscale Values is checked. Reserve one value at the uppermost end of the range to be used to code invisible pixels that represent missing (invisible) values.</td>
</tr>
<tr>
<td><strong>Save result as new component</strong></td>
<td>Convert data and save as a new surface component in the project pane. When this option is checked, read-only surfaces (such as those linked in from an Enterprise server if Enterprise Edition is being used) may be converted.</td>
</tr>
</tbody>
</table>

The size readout at the bottom of the dialog gives the size of the surface in kilobytes using the selected numeric type.
Surface - Contours

The Contours dialog works with surfaces to create a drawing that includes areas representing contours from the surface.

To create contours:

1. Open a surface in a surface window, or click on a surface layer in a map.
2. Choose Surface - Contours from the main menu.
3. Supply a Name for the drawing to be created and (optionally) a description.
4. Choose the type of contours to be created in the Create box.
5. Specify the contour values to be used in the Height pane.
6. Press OK.

To specify values to be used in the Height pane:

1. Click the Add button.
2. Double click into the resulting new row and change the Height value to the value desired.
3. Organize the heights by using the Move Up / Down / to Top / to Bottom buttons.

Note that the Contour dialog refers to "heights" because most often in a GIS context it is used with surfaces that represent terrain elevation data. It can also be used to create contours with abstract data where the value in the surface represents some other value such as temperature or population.

<table>
<thead>
<tr>
<th>Name</th>
<th>Name for the drawing to be created that will contain the contours.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>Optional description for the drawing.</td>
</tr>
<tr>
<td>Create</td>
<td>How contours will be created:</td>
</tr>
<tr>
<td></td>
<td><strong>Areas above heights</strong> - Create contour areas that show all locations higher than a particular contour height. Contour areas for higher heights will overlap contour areas for lower heights. This is the “wedding cake” effect.</td>
</tr>
<tr>
<td></td>
<td><strong>Areas below heights</strong> - Create contour areas that show all locations lower than a particular contour height. Contour areas for lower heights will overlap contour areas for higher heights. This is the “inverse wedding cake” effect.</td>
</tr>
<tr>
<td></td>
<td><strong>Areas between heights</strong> - Create contour areas that show all locations with height between the height intervals given. No contour areas will overlap. The most frequently used option when creating contour areas.</td>
</tr>
<tr>
<td></td>
<td><strong>Lines</strong> - Create lines at a given contour level. The classic</td>
</tr>
</tbody>
</table>

3417
contour line effect use within printed topographic maps.

**Heights Pane**
A list of heights to be used for contours. Can also be used to specify abstract values when a surface represents data other than terrain elevation.

- **Move to Top** - Move the highlighted height range to the top of the heights pane.
- **Move Up** - Move the highlighted height range up one position in the heights pane.
- **Move Down** - Move the highlighted height range down one position in the heights pane.
- **Move to Bottom** - Move the highlighted height range to the bottom of the heights pane.
- **Delete** - Delete highlighted height range from the contours to be created.
- **Add** - Add a new height range from the contours to be created.

**Example**

Visiting the USGS web site we’ve downloaded the **Montara Mountain** 1:24K-scale SDTS file that provides a DEM module for terrain elevation. We’ve imported it as a surface. Open the surface in a window.

Choose **Surface - Contours** to launch the **Contours** dialog.
In the **Contours** dialog click **Add** to add a new row in the **Heights** pane.

<table>
<thead>
<tr>
<th>Height</th>
</tr>
</thead>
<tbody>
<tr>
<td>1000.00</td>
</tr>
<tr>
<td>3</td>
</tr>
</tbody>
</table>

Double click into the new row that's created and add a **Height** of 3.

<table>
<thead>
<tr>
<th>Height</th>
</tr>
</thead>
<tbody>
<tr>
<td>1000.00</td>
</tr>
<tr>
<td>100</td>
</tr>
<tr>
<td>3</td>
</tr>
</tbody>
</table>

Click **Add** again and add a **Height** of 100.

<table>
<thead>
<tr>
<th>Height</th>
</tr>
</thead>
<tbody>
<tr>
<td>1000.00</td>
</tr>
<tr>
<td>500</td>
</tr>
<tr>
<td>250</td>
</tr>
<tr>
<td>100</td>
</tr>
<tr>
<td>3</td>
</tr>
</tbody>
</table>

Click **Add** and add **Heights** at levels of 250 and 500 as well. Press **OK**.

The result is a new drawing in the project. If we open the drawing we see it consists of non-overlapping areas, where each area shows the contours between a given height range. The drawing's table has one field, the **Height** field, which gives the value of Height used to create each area.
We can thematically color the new drawing using thematic formatting controlled by the **Height** field, or simply by using the Color dialog to quickly color the areas with different colors.

For a nice effect, we can create a map using the original surface and then drag and drop the thematically colored contour drawing into the map in a layer above the surface. We then change the opacity of the drawing’s layer to 50%. This creates a visual mixture of the thematically formatted contours and the surface shading.

Another classic map can be created by choosing the **Lines** option in the **Create** box in the **Contours** dialog and to then layer the resultant contour lines in a map above the surface, or to use contour lines drawing in a map above a different drawing.

When the **Lines** option is chosen for the **Create** parameter, Manifold will add a **Height** numeric column to the table associated with the contour lines drawing with the height of each contour line in that column. This makes it easy to label contour lines with their height.
Terrain Menu

Terrain - Surface

The **Surface** dialog for terrains specifies how the data surface that defines the terrain should be visualized. Includes options such as the texture used for the surface, the color determined by the elevation, the level of details computed and the size of the data set in view.

### Surface Dialog Controls

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Palette</strong></td>
<td>Choose from preset color gradients that will be used to color the surface based on the elevation value.</td>
</tr>
<tr>
<td><strong>Apply</strong></td>
<td>Apply the chosen palette to terrain.</td>
</tr>
<tr>
<td><strong>Reverse</strong></td>
<td>Reverse the colors used in the values box from high to low.</td>
</tr>
<tr>
<td><strong>Interpolate</strong></td>
<td>Change the colors used in the values boxes by interpolating between the top and the bottom boxes. A quick way of creating smooth gradients of colors or sizes.</td>
</tr>
<tr>
<td><strong>Lighten</strong></td>
<td>Lighten all colors in the values boxes. Each click of the Lighten button lightens the colors a bit more.</td>
</tr>
<tr>
<td><strong>Darken</strong></td>
<td>Darken all colors in the values boxes. Each click of the Darken button darkens the colors a bit more.</td>
</tr>
<tr>
<td><strong>Grayscale</strong></td>
<td>Convert all colors in the values boxes to grayscale.</td>
</tr>
<tr>
<td><strong>Load from File</strong></td>
<td>Load a previously saved palette from an XML file.</td>
</tr>
<tr>
<td><strong>Save to File</strong></td>
<td>Save this palette to an XML file.</td>
</tr>
<tr>
<td><strong>Texture</strong></td>
<td>The texture applied to the surface, such as a variety of stone or other textures.</td>
</tr>
<tr>
<td><strong>Details</strong></td>
<td>Choose a level of detail to be computed, from <strong>Full</strong> to <strong>Lowest</strong>. Higher levels of details will require more computation and will result in slower display within the terrain window.</td>
</tr>
<tr>
<td><strong>Display</strong></td>
<td>The number of tiles to show in the terrain window. Terrains are subdivided into a smaller number of square tile regions, with each tile being 32 x 32 pixels. Operating with a larger number of tiles will increase the apparent extent of the surface in view in the terrain window. Increasing the number of tiles will slow down operation.</td>
</tr>
<tr>
<td><strong>Z scale</strong></td>
<td>Factor to apply in rendering height. A value of 0.50 will render heights half as high as their elevation values would suggest. A value of 2.00 renders heights twice as high.</td>
</tr>
<tr>
<td><strong>Walls</strong></td>
<td>Show the terrain with vertical &quot;walls&quot; at the edges of the terrain.</td>
</tr>
<tr>
<td><strong>Wireframe</strong></td>
<td>Show the terrain as a wireframe mesh instead of as a continuous surface.</td>
</tr>
<tr>
<td><strong>Preview</strong></td>
<td>Check this box to show the effect of options in the terrain window as they are altered.</td>
</tr>
</tbody>
</table>
Choose a collection of options, using **Preview** if desired to see the effects and then press **OK** to apply them to the terrain window.

> When choosing a new palette, don’t forget to press the **Apply** button to load the values from that palette.

**Keyboard Shortcuts for Z Scale in Terrain Windows**

With the focus on the terrain window we can use the following keyboard shortcuts to modify **Z scale**.

- **Page Up**  Increase Z scale by .01
- **SHIFT-Page Up**  Increase Z scale by .10
- **Home**  Set Z scale to 1.0
- **Page Down**  Decrease Z scale by .01
- **SHIFT-Page Down**  Decrease Z scale by .10

**Examples**

![Texture Example](image1)

![Texture Example](image2)

**Textures**: The upper image has no texture applied. The bottom image has a rough surface texture applied. Textures can provide a greater sense of reality.
Display: The three images above show an increasing number of tiles. The first image has the least number of tiles and shows terrain only in the foreground. The middle image adds more tiles, so the displayed terrain extends further towards the horizon. The last image has the greatest number of tiles used and so extends even further to the horizon. Tiles are square pieces of terrain that are 32 x 32 pixels in extent.

Details: This setting specifies what percentage of the data set is used to render the 3D terrain. The upper image uses Full details while the lower image uses Lower details. Lower Details settings will display faster but will simplify the terrain by using fewer data points from the terrain data set. Note how the lower image is an interpolated approximation to the upper image.

Palettes are a sequence of colors that are applied to the 3D surface depending on the elevation of the surface. Manifold provides numerous preset palettes.

<table>
<thead>
<tr>
<th>Elevation</th>
<th>Color</th>
</tr>
</thead>
<tbody>
<tr>
<td>540.0000</td>
<td><img src="image1.png" alt="Color" /></td>
</tr>
<tr>
<td>1006.0000</td>
<td><img src="image2.png" alt="Color" /></td>
</tr>
<tr>
<td>1436.0000</td>
<td><img src="image3.png" alt="Color" /></td>
</tr>
<tr>
<td>1922.0000</td>
<td><img src="image4.png" alt="Color" /></td>
</tr>
<tr>
<td>2380.0000</td>
<td><img src="image5.png" alt="Color" /></td>
</tr>
<tr>
<td>2338.0000</td>
<td><img src="image6.png" alt="Color" /></td>
</tr>
</tbody>
</table>

The palette used in the illustrations above will color the surface in a series of green colors from a lighter green to a green brown in higher elevations and then finally to a brighter green at the highest elevations.
Most of the terrain visible in these illustrations, like the screen shot above, is at elevations lower than the dark brown band and is therefore colored in the lower two bands.

Palette colors can be changed at will. For example, we can double click into the green color well just before the brown well and change it to bright yellow.

The result in the terrain window will be that terrain elevations from 1464 to 1922 will be colored bright yellow.

Different palettes may have greater or fewer divisions and color wells. Although many palettes are available to color terrains in a realistic way, some palettes are designed for use with purely abstract data.

These may be applied to terrains for otherworldly effects, or simply to color-code data shown in the terrain window.

 Wireframe
The **Wireframe** option shows the terrain as a wireframe mesh instead of as a solid surface. The colors of the wires will be taken from the palette color and texture for that part of the surface.

**Walls**

The **Walls** option turns on vertical panels that "close in" the area underneath the terrain and provide greater orientation when the terrain is seen from far away.
Terrain - Overlay

The Terrain - Overlay dialog allows us to overlay the terrain surface with images, objects from drawings, labels or other surfaces. Multiple images, drawings, labels and surfaces can be overlaid at the same time.

Images will be re-sampled and "spray painted" or "draped" onto the terrain surface. Objects from drawings will be converted into equivalent 3D objects and placed within the 3D terrain landscape. Colors used for drawing objects overlaid onto the terrain will be taken from their formatting in their home drawing.

To Overlay an image or other component onto a Terrain

1. Verify that the terrain and all components to be overlaid are correctly georegistered by viewing the terrain's surface and the components together in a map.
2. Open the terrain in a terrain window.
3. Choose Terrain - Overlay.
4. In the Components pane, check the boxes of the components to be overlaid. Use the move buttons in the dialog's toolbar to move components up and down to the order in which they are to be overlaid.
5. Choose options as desired for areas, labels, lines and points, and press OK.

The choices in the Terrain - Overlay dialog allow control over how drawing objects are represented by 3D objects in the terrain view.

- **Show All** - Show all available components overlaid on the terrain surface. Check all the boxes.
- **Show None** - Do not overlay any components on the terrain surface. Uncheck all boxes.
- **Show Inverse** - Invert checkboxes. Uncheck those previously checked, and check those that were not checked.
- **Move to Top** - Display the highlighted component uppermost when overlaid on the terrain.
- **Move Up** - Move the highlighted component up one position in the overlay stack.
- **Move Down** - Move the highlighted component down one position in the overlay stack.
- **Move to Bottom** - Display the highlighted component at the bottom of the overlay stack.

**Areas**

- **Embed into texture** - Show areas by embedding them into the textured surface of the terrain.
- **Paint over terrain** - Show areas by creating 3D area objects just above the terrain surface. Area objects will take their colors from formatting used in the drawing.
- **Opacity** - Opacity to use for areas drawn in the terrain. Enabled only when Paint over terrain option is checked.
- **Walls** - Check to display vertical "walls" which are the extruded vertical sides of areas shown in the terrain. Walls are drawn using the color specified for the area's border and using the Opacity specified for the area in this dialog. Enabled only when Paint over terrain option is checked.
- **Vary height by column** - Check to vary the altitude over the surface at which the area is drawn using the contents of a data field (column) called Height in the drawing's table. Enabled only when Paint over terrain option is checked. The height is reckoned over the highest...
location in the surface under the area. If the value of height is less than zero it is set to zero. The values in the Height column are assumed to use the same units as the surface.

Labels  Display options for labels:

Embed into texture - Show labels by embedding them into the textured surface of the terrain.

Paint over terrain - Show labels by creating 3D label objects just above the terrain surface. Label objects will take their style from the label style and colors used in the labels component. 3D labels will always face the viewer in the terrain window. To create 3D labels consisting of "text only" use a transparent background color for the labels in the labels component.

Size  - Relative size of labels.

Height  - Height in pixels above the surface to position labels

Spacing  - Interval in pixels between labels attached to lines.

Piers  - Check to display rod-like vertical supports under labels.

Lines  Display options for lines:

Embed into texture - Show lines by embedding them into the textured surface of the terrain.

Paint over terrain - Show lines by creating 3D line objects just above the terrain surface.

Size  - Relative thickness of lines.

Height  - Height in pixels above the surface to position lines

Smooth line body - Apply antialiasing to provide a smoother appearance for lines.

Piers  - Check to display rod-like vertical supports under lines at each coordinate defining the line.

Points  Display options for points:

Embed into texture - Show points by embedding them into the textured surface of the terrain.

Paint over terrain - Show points by creating 2D or 3D point objects just above the terrain surface.

Size  - Relative size of point symbol used to display points.

Height  - Height in pixels above the surface to position point symbol.

Style  - 2D icon or 3D shape to be used as a symbol for points.

Frame 2D Symbols - Draw a wireframe rectangle about 2D point symbols using the foreground color used for points in the component.

Texture Opacity  Opacity to use for the generated texture when embedding labels, areas, lines or points into the terrain. 60% by default. The partial transparency used by the default setting makes the embedded texture seem a part of the terrain. The same opacity value will be applied to all overlaid components.
**Preview**  Check to see how options will appear in the terrain window as they are chosen.

Check one of the display options (Embed into texture or Paint over terrain) to show areas, labels, lines or points in the overlay. If neither Embed into texture nor Paint over terrain is checked, then objects of that type will not appear in the overlay.

Overlays can be very slow to initially compute with graphics cards that do not support textures in hardware. Even in fast cards, the initial computation of an overlay can take a few minutes. Once the terrain redispays with the overlay, viewing will continue at the normal speed.

**Example**

We've created a map that has a labels layer over a surface layer created from the Montara Mountain sample surface from the Manifold CD.

![Map Image](image)

To add labels to a terrain we begin by opening the terrain.

![Terrain Image](image)

In the terrain we have navigated using keyboard navigation commands to a view over Pilarcitos Lake. The terrain has been colored using the Altitude palette. The view is toward the Southeast.
We open the Terrain - Overlay dialog and in the components pane we check the Labels component to be overlaid.

In the Labels portion of the dialog, we check the Paint over terrain box and uncheck the Embed into texture box. Press OK.

The result is that a label appears over Pilarcitos Lake just as it does in the map. The small vertical line under the label is the pier.
Note that when changes are made in the labels component those changes will be updated in the terrain window as well. For example, if we click on the labels layer in the map and change the formatting of the label so it uses blue background color and a label style that surrounds the letters in background color this change will also appear in the terrain window as well.

A good way to adjust the appearance of labels in a terrain window is to open the labels component in a second, small window and to make changes in label formatting in the labels window until the desired appearance is achieved in the terrain window. As the labels are changed in the labels window the terrain window will also be updated with labels in the same formatting.

Here is an example of labels embedded into the texture and shown with partial opacity.

Example
The choice of how lines are overlaid will greatly affect the appearance of lines from drawings that are shown in terrain windows. In this example, we have overlaid the Montara Mountain sample surface with roads taken from a 1:24K-scale USGS SDTS drawing.

Using **Embed into texture** and unchecking **Paint over terrain** the line appears as part of the surface texture of the terrain.

If we also check **Paint over terrain** we can simultaneously paint the line floating slightly over the terrain. We have lowered the **Texture opacity** to 20% in order to achieve a pseudo-shadow effect for the line embedded in the surface.

Note that painting lines over the terrain will result in sharper line rendering since this method is not constrained by the resolution of the terrain texture. Rendering overlaid lines by embedding them into the surface texture will often lower the resolution of lines because the texture cannot be rendered within any greater pixel resolution than that computed for the surface seen in the 3D terrain view.

Here we have unchecked the **Embed into texture** choice and have checked the **Piers** option. This option draws vertical supporting "piers" at each coordinate point that defines the line.
Finally, we can uncheck the Piers option to show just the line itself floating slightly above the surface. It is usually important to paint lines with some height above the surface so that the line does not intersect any interpolated bumps in the surface that would hide the line. Therefore, the default Height parameter is set to 50%.

**Pay Attention to Geographic Location**

Note that if the terrain is located in a different place than the images or drawings that are overlaid upon it, there will be no visual effect seen in the terrain window. This may seem to be an obvious comment; however, it is easy to forget that some components have been georegistered and others have not yet been georegistered. Check georegistration by showing the terrain together in a map with any other components that are to be overlaid upon the terrain.

Terrains can be georegistered by georegistering their associated images. Any image that is to be overlaid onto a terrain should also be georegistered. Although drawings are frequently imported from formats that automatically result in a georegistered component within Manifold, it is possible that drawings imported from CAD formats or other non-geographic formats are not yet georegistered. These should be georegistered before being overlaid onto a terrain that has already been georegistered.

**Notes on Resolution**

A common task is to overlay an image onto a terrain to give the terrain a more photorealistic look. Since it is usually the case that images used to overlay a terrain are not exactly the same resolution as the surface used to create the terrain, Manifold will automatically interpolate colors from the image's pixels to compute the required color for each individual surface pixel used to create the terrain.

Therefore, the maximum display resolution for an image overlaid upon a terrain will be the resolution of the surface used to create that terrain. If the surface is 1000 pixels by 1000 pixels and it is overlaid by an image that covers the same region in 10000 pixels by 10000 pixels, then each surface pixel will be colored by an interpolation of the 100 image pixels that fall within it. The resulting terrain will not appear to be "painted" with an image as detailed as the original image used for the overlay.

To allow use of greater detail from images that are higher resolution than the surfaces in use, use the Surface - Resize command to increase the number of pixels used by the surface. Alternatively, use a higher resolution surface covering the same region.

**See Also**

Overlays - For example of overlays of drawings and surfaces.
Area Overlays - Areas overlaid on terrains with 3D walls.
Terrain - Clouds

The terrain window can display synthetic "clouds" in the sky provide a greater sense of reality. The Terrain - Clouds dialog provides options that control the appearance of the clouds.

- **Show clouds**: Check this box to display clouds in the terrain view.
- **Quantity**: Choose a value for the relative number of clouds that appear in the sky.
- **Size**: Specify the relative size of clouds.
- **Opacity**: Specify how opaque clouds will be. Low opacity results in fainter, hazy clouds.
- **Preview**: Check to see how options will appear in the terrain window as they are chosen.
**Terrain - Fog**

Fog is an effect created in a terrain window by applying a color to an increasing amount to points located at an increasing distance from the viewer. The visual result is very similar to that of real haze or fog, which has a greater effect on distant points because they are seen through more haze. The **Terrain - Fog** dialog provides options to control the appearance of fog in the terrain window. Applying fog to a terrain enhances the sense of 3D realism.

- **Show fog**: Check this box to display fog in the terrain view.
- **Render fog from**: Show fog from the nearer percentage to the greater percentage of the visible range.
- **Color**: Color of fog to use. This is normally the same as the color of sky, a very light blue.
- **Preview**: Check to see how options will appear in the terrain window as they are chosen.

**Examples**

![Default fog](image1)

Default fog. A slight amount of fog applied to a terrain enhances reality by providing haze in the distance.

![Increased fog](image2)

We can increase the fog by increasing the nearer number in the **Render fog from** parameter. This provides a hazier landscape.

![Color change](image3)

Changing the color of fog changes the color of the sky as well, since sky is just fog color piled up to an infinite distance. Color shown is a dark gray color. Using black and a slight amount of fog creates night effects.
Terrain - Lighting
Terrain windows can provide relief effects as though the 3D terrain surface is illuminated from the side, causing highlights and darker regions in the surface. Lighting effects are usually required to provide a credible 3D simulation. Lighting options are set in the Terrain - Lighting dialog.

- **Show lighting effects**
  Check this box to show lighting effects in the terrain view.

- **Amount**
  Increasing the amount will increase the darkness of lowlights and the brightness of highlights.

- **Angle**
  Specify the direction from which the light originates. Angles are given in geographic compass directions.

- **Preview**
  Check to see how options will appear in the terrain window as they are chosen.

Examples

Without lighting effects the landscape lacks visual relief. The darker shades are caused by the palette, which in this example is set to color the surface with darker colors at higher elevations. Wise use of palettes can provide 3D visual cues and a more depth-like appearance, but not as much as lighting effects.

Applying lighting from the default South-East angle immediately provides depth and relief to the landscape. The highlights and darker tones appear as if a light source was located to the Southeast of our location. In this example, we are facing North in the terrain view.

Changing the Angle of illumination will at times result in dramatically different appearance. In this example we have changed the angle to North-East so that the low cliffs facing us down by the water become shadowed.
Increasing the Amount lighting provides a starker effect, with brighter highlights and darker shadows.

**Notes**

Lighting effects in the terrain window are a simulation that approximates the true physics of lighting. Darker regions are not true, cast shadows. Rather, they are regions of the surface that have been computed to face away from the light source and so are rendered darker. The approximation is nonetheless very credible and useful as a means of showing the 3D structure of the surface.

The Angle setting allows us specify lighting angles that are not possible locations for sun angles. For example, the terrain used in the example is a section of the Grand Canyon, which is located in the Northern Hemisphere in the Southern part of the United States. Sun angles at the Grand Canyon are usually more Southerly and are never North-East as shown. Using angles other than those possible as sun angles can be a good way of bringing out 3D nuances in the terrain surface that would otherwise be hidden.
Terrain - Water

Terrain windows can display a horizontal "waterline" plane cutting through the surface that is used to simulate the appearance of water in the landscape. The Terrain - Water dialog options specify the appearance of the waterline plane.

- **Show water**: Check this box to display water in the terrain view. Checked on by default.
- **Level**: Specify the water level from lowest to highest elevation value in the terrain.
- **Density**: Controls the "density" of the water. As water becomes denser it is more difficult to see through, especially from a viewpoint within the water.
- **Opacity**: Specify how opaque water will be. Low opacity results in transparent water that allows the submerged terrain surface to show through. Slight opacity provides a "depth" effect.
- **Color**: Click into the color well to change the color used for the water.
- **Preview**: Check to see how options will appear in the terrain window as they are chosen.

**Examples**

The default waterline plane appears as a river within the terrain.

Increasing the **Level** has the effect of moving the water level upwards and flooding the terrain. This is a topologically accurate effect so that waterline analysis may be done to determine visually which parts of the terrain are at the same level.
Decreasing **Opacity** causes the water to become more transparent and thus allow some of the terrain surface to show through. If we carefully compare this illustration and the previous one we can see that the water in the previous illustration was not fully opaque. The slight transparency of the water allowed part of the dark shadow of the headland to show through and thus give the water a sense of "depth."

We can change the color if a different water color is desired. In the example above we’ve changed color and transparency to achieve a muddy water effect, a more credible color in the case of flooded terrain.
Terrain - Snap to Surface

The **Snap to Surface** command toggles automatic snapping of the terrain camera to terrain-following mode, so that in response to any keyboard navigation commands the camera moves just slightly above the terrain elevation. The effect is somewhat like driving a car over the surface.

The view we see in a terrain window may be thought of the viewpoint of a camera located at a particular position over the terrain and aimed in a particular direction. Using the keyboard navigation keys specified in the Terrains topic, we can move the camera and point it in whatever direction we like.

Sometimes we would like to move the camera about the terrain while staying just above the terrain's surface, almost as if we were walking up and down the terrain with our eye-level just above the terrain surface. This can be very tedious to do using keyboard commands, so Manifold provides a terrain-following "automatic pilot" of sorts in the form of the **Snap to Surface** command.

When **Snap to Surface** is turned off, the camera flys about following whatever keyboard navigation commands we issue. For example, if the camera is pointed forward with no upward or downward tilt and we issue a **W** command to move forward the camera will move forward at the same altitude. If we tilt the camera down with the down arrow on the keyboard and then issue a **W** command the camera will move forward and downwards at the tilt angle used. With **Snap to Surface** turned off, we can freely "fly" the camera like an airplane.

When **Snap to Surface** is turned on the camera descends vertically down from whatever current location it is at and then responds to all keyboard navigation commands by moving just slightly above the terrain surface. Keyboard navigation commands to increase the elevation of the camera, such as the **Q** command to move vertically upward, are ignored. With **Snap to Surface** turned on, we can freely "drive" the camera over the surface like a car.

Terrains

Window Menu

The **Window** menu allows us to arrange windows within the main Manifold window.

- **New Window** - Enabled when a window is activated. Open a new window into that component.
- **Close** - Close the active window.
- **Close All** - Close all windows.
- **Next** - Activate the next window in the stack.
- **Previous** - Activate the previous window in the stack.
- **Cascade** - Arrange windows neatly in front of each other and offset slightly.
- **Tile Horizontally** - Arrange windows next to each other left to right and resize so they fill the main window.
- **Tile Vertically** - Arrange windows next to each other top to bottom and resize so they fill the main window.
- **Windows...** - Open a dialog that lists all windows.

See the Windows Dialog topic for additional info.
Window - Windows Dialog

The Windows dialog within the main Window menu shows a list of all windows open within the main Manifold window. We can use this dialog to activate (that is bring to the top) any window or to close several windows at once.

- **Activate** - Move the highlighted window to the top of the windows stack and make it the active window.
- **Close** - Close the highlighted windows.
- **Cascade** - Arrange windows neatly in front of each other and offset slightly.
- **Tile Horizontally** - Arrange windows next to each other left to right and resize so they fill the main window.
- **Tile Vertically** - Arrange windows next to each other top to bottom and resize so they fill the main window.

**Activate** Move the highlighted window to the top of the windows stack and make it the active window. Same as the Activate toolbar button and added to provide a similar look to the equivalent dialogs in Microsoft products.

**Close** Close the Windows dialog.

Example

Suppose we have four windows open showing various components in our project as seen above.
The **Windows** dialog would appear as above. Note that the **roads data** window is at the top of the list. The list shows the windows in their order in the windows stack. Each window listed will be shown with a small icon for the type of component it is.

We can click on the **roads data** window entry to highlight it and then **CTRL click** on the **SanFran** entry to highlight it as well.

If we now click the **Close** toolbar button both the **roads data** and the **SanFran** windows will be closed.

The **Windows** dialog will be updated with a new list of windows:
Tech Tip

Queries can be opened in two forms, either as a query window allowing the query text to be edited or in the form of a table window that reports the results of a query being run. As a convenience for users, if a query is open at the same time as an editable query window and also as a table window reporting the results of the query being run, the Windows dialog will append the postfix (Table) to the latter. For example, if we have a query called MyQuery and it is open both as an editable query window and also as a table window reporting the results of running the query, the Windows dialog will show two windows open, one called MyQuery and the other called MyQuery (Table).

Help Menu

Help - Activate

Each serial number that authenticates a license for Manifold System product has a limited number of activations. Therefore, it is critically important for users to read and understand the Activation Keys and Serial Numbers topic before using the Help - Activate command.

When first launched after installation, Manifold System raises the Activation dialog to allow entry of a serial number for preliminary functioning or the entry of both a serial number and an Activation key for permanent installation. At any time thereafter, the Help - Activate command may be selected to re-activate the system. Before using this command, it is wise to check the Help - About dialog to see what Manifold System edition and extensions have already been activated on the subject system.

Typical uses of the Help - Activate command include:

- Changing the serial number of a system to a different serial number during the preliminary installation period when running on serial number alone.
- Changing the serial number of a system to a different serial number after permanent installation (requires use of an Activation key).
- Installing a different Manifold edition, such as installing Enterprise Edition on a machine on which Professional Edition has already been installed. In that case, we would raise the Help - Activate dialog to allow entry of the new Enterprise Edition serial number and Activation key.

When Help - Activate is launched, the system will close any open projects and raise the Activation dialog to allow entry of a serial number or a serial number and an Activation key. The system will then shut down Manifold so that Manifold may be re-launched with fresh activation information.

A related dialog is the Help - Activate Extension dialog, which is used to turn on an optional extension such as Business Tools, Geocoding Tools or Surface Tools.

Note: The Help - Activate command is not used when a Manifold installation is running with license authorization from a Manifold License Server. In that case, the Help - Activate command has no effect on the License Server authorization because a License Server authorization always takes precedence over any local activation status.

Controls

Serial number  A serial number authenticating a Manifold System license. Serial numbers must match the release level of the Manifold System product. For example, after
installing Manifold System Release 7.00, a 7.00 Manifold System serial number must be used. A 6.50 Manifold System serial number won’t work.

**System ID**
An identifier for this particular installation. The System ID is automatically generated by Manifold and cannot be edited. It can be copied by highlighting the System ID and using `CTRL-C` or by right-clicking on the highlighted System ID and choosing **Copy** in the context menu.

**Activation key**
An Activation Key fetched using the serial number and System ID. Activation keys may be fetched automatically if the computer is connected to Internet, or they may be fetched manually. After a period of 30 days from the date the serial number was issued, an Activation key is required along with the serial number to activate Manifold.

**Accept**
Accept the serial number and (if entered) the Activation key.

**Cancel**
Abandon the activation process.

**Get Activation Key via the Web**
After entering a valid serial number, press this button to fetch an Activation key automatically if the computer is connected to the Internet. When this button is pressed, Manifold will take the **Serial number** provided together with the **System ID** and will connect to the Manifold key server via the web and request an Activation key for that **Serial number** and **System ID**.

**Caution:** getting an Activation key via the Web will use up one of your five activations. Do not fetch an Activation Key unless you are ready to immediately activate Manifold for permanent use on this computer.

If all five activations already have been used up, or if the serial number is not valid, getting an Activation key via the web will fail.

**Example**

John installed and activated a Manifold System Professional Edition license on a machine in his department several months ago. Since then, his company has acquired a few dozen Enterprise Edition licenses for installations and now installs Enterprise Edition on all machines. John would like to upgrade the one remaining Professional Edition machine to Enterprise Edition.

John acquires an Upgrade to Enterprise Edition product on the Manifold Online Store, trading in the Professional Edition license by providing the serial number for that Professional Edition license during the checkout process for his upgrade purchase. He gets an email with the new Enterprise Edition serial number for the upgrade.

John launches the Help - Activate dialog and enters the new Enterprise Edition serial number provided to him for his upgrade. He does not enter an Activation key. When he presses **Accept** Manifold shuts down. The next time John launches Manifold, the Activation dialog pops open to let him know how many days he has left in the preliminary installation period of his Enterprise Edition serial number. John clicks **Accept** to continue though the dialog to launch Manifold in the usual way. He sees that Enterprise Edition features have been enabled.

After a few days, John realizes there is no point in procrastinating and he may as well activate the Enterprise license on this machine, so the next time he launches Manifold and the Activation dialog pops open he presses the Get Activation Key via the Web button to automatically fetch an Activation key. He presses **Accept** and now Manifold is activated on that machine as Enterprise Edition.

**Note**

If you have several Manifold System licenses you can determine which serial number was used on a particular system as well as which extensions, if any, have been activated by launching the Help - About dialog.

Activation Keys and Serial Numbers
Installing and Activating a Manifold Extension
Help - Activate Extension

Each serial number that authenticates a license for a Manifold System extension product has a limited number of activations. Therefore, it is critically important for users to read and understand both the Activation Keys and Serial Numbers topic as well as the Installing and Activating a Manifold Extension topic before using the Help - Activate Extension command.

The Help - Activate Extension command is used to turn on the Business Tools, Geocoding Tools or Surface Tools optional extensions to Manifold System. When Help - Activate Extension is launched, the system will close any open projects and raise the Extension Activation dialog to allow entry of a serial number or a serial number and an Activation key. The system will then shut down Manifold so that Manifold may be re-launched with fresh activation information. When Manifold is re-launched it will automatically be reconfigured so that the activated extension will be fully enabled. Before using this command, it is wise to check the Help - About dialog to see what Manifold System edition and extensions have already been activated on the subject system.

There is no need to specify which extension is being turned on, since each serial number contains coded information specifying the extension that it activates. For example, if you license the Surface Tools package from manifold.net you will receive a Surface Tools serial number. Entering that serial number into the Extension Activation dialog will automatically turn on Surface Tools.

Just like the serial number used to enable Manifold, serial numbers for extensions typically allow a temporary period of usage, normally 30 days, without requiring an Activation key. This preliminary operation period allows time for users in remote areas to acquire an Activation key while still being able to use the extension. While an extension is operating on serial number alone the Help - About dialog will report how many days are left on that serial number before an Activation key is required.

 Activation Keys and Serial Numbers
 Installing and Activating a Manifold Extension
Help - About
In addition to copyright and trademark information the Help - About dialog lists the following information about the your Manifold System installation:

- **Edition** - The edition of Manifold System installed, such as Professional Edition or Enterprise Edition.
- **Build / Version Number** - Provide this number to technical support if you ever contact technical support in connection with a support incident.
- **Installed extensions** - Provides a list of optional extensions, such as Business Tools, Geocoding Tools or Surface Tools that have been enabled via the Activate Extension dialog. Extensions activated with a serial number alone will report how many days are left on the serial number. Extensions activated both with a serial number and a permanent Activation key will not show a time to expiration.
- **Serial Number** - The serial number used to install this license. The last few digits are concealed with "X" characters to keep your full serial number secret. You can use the leading digits to determine which serial number was used to install this license if you have several serial numbers. The "X" masked version of the serial number cannot be used to fetch activation keys - this is to protect your serial number from unauthorized use.
- **CPU** - The central processing unit reported by Windows.
- **GPU** - Whether the graphics processing unit is CUDA capable or not.
- **RAM** - The amount of dynamic RAM memory reported by Windows as installed in the computer. Note that 32-bit versions of Windows may report less than the full amount of physical RAM actually installed.
- **Operating system** - The Windows version and build reported by Windows.
- **32-bit or 64-bit mode notice** - This status line indicates whether Manifold is running in 32-bit mode or 64-bit mode.

Manifold Build / Version Numbers

Manifold build numbers (sometimes referred to as version numbers) have four parts separated by dots, for example, 7.1.0.67. We may read this example as follows:

- The first two parts identify the **product version** so that 7.1 indicates release 7.1, the immediate successor to release 7.00. For marketing purposes, 7.1 series product releases are collectively known as the 7x generation.
- The third part identifies the **patch number**. Patch numbers are incremented to indicate any updates issued after initial release. In the example, a 0 indicates this is the original release of this product iteration and is not a subsequent patch.
- The fourth part is a revision number used mainly within manifold.net to identify various internal candidate builds created on the way to publication of new product version and patch for public use. In the example this is revision 67.

Note that Manifold build / version numbers have changed with 7x and subsequent product releases. The old system used a single number, such as "Build 429" which increased linearly. The new system provides a four-part nomenclature to help keep track of more frequent builds and more frequent updates.

Help - Check for Updates

The **Automatic Updates** page in the Tools - Options dialog sets up Manifold to automatically check via Internet for any updates that may have been issued to the currently running release.

The **Check for Updates** command provides a manual way to check for updates. Launching the command tells Manifold to connect to the manifold.net update server, checks to see if there have been any updates issued for the currently running version of Manifold and, if so, will pop open a message inviting the operator to visit the update site.

No information is ever transmitted to the update server and no data except information on published updates is ever downloaded from the update server.

This command requires Internet access for Manifold using ordinary HTTP protocol, the same as used by web browsers like Internet Explorer. If the computer is not connected to Internet or if HTTP is blocked by a firewall or other security mechanism, this command cannot work. In general, if you can launch a web browser and visit web sites from your computer this command will work.

**Installing Updates**

Many customers do not like complex software to alter their systems, so Manifold updates must be consciously downloaded and installed. In addition, some updates such as major new releases may not be free but may require payment of a license fee.

The automatic update notification system will notify you when a new update is available and will offer to launch the web page for that update. You will only be able to view that web page if your computer is connected to Internet and you have an Internet browser, such as Internet Explorer or other browser, installed on your computer.

Read the updates web page carefully for instructions on downloading the update, uninstalling your previous Manifold installation and then installing the update.

**Automatic Updates** in Tools - Options
Help - Contents

Manifold Help uses the standard Microsoft Help system or a web-based browser version if a local Help file has not been installed. Selecting the Help - Contents command launches Help set to the Contents tab, which displays the top level of the Help "outline" structure of topics, showing the main list of Help "books," or chapters.

The Contents command is the first choice for either reading Help in sequential fashion or for drilling down through the chapters to find a topic that is (presumably) arranged in logical order within the hierarchy. We can then explore Help by following hyperlinks (shown in boldfaced underlined green text like those in the See Also section below) to read related topics, discover definitions of Manifold terms of art and so on.

Help is a very large document, with thousands of pages of information. There's no hope of learning Manifold efficiently if we do not learn to make savvy use of Help facilities such as Contents, Index and Search.

Installing Help

Manifold displays the web-based version of Help by default. To install a local version that may be used if your computer is not connected to Internet, please see the How to Install this Documentation topic.

See Also

Help - Index
Help - Search
Help - Index

Manifold Help uses the standard Microsoft Help system. Selecting the Help - Index command launches Help set to the Index tab, which displays a list of all text words and phrases that have been indexed by the authors of Help.

The Index command is a good way to find top-level, reasonably major words and phrases of interest. Entering the first letters of a word or phrase will scroll the list of entries to those that lexicographically match those letters. Clicking an entry and pressing the Display button will launch the Topics Found dialog that lists all topics in which that indexed entry is found.

Because it has been compiled by actual humans, Index tends to have fewer "hits" than the Help - Search function. The downside is that it is not as relentlessly comprehensive as the machine-compiled Search list. The usual order is to check the Index first and then second to use the Search function via the Find tab.

Help is a very large document, with thousands of pages of information. There's no hope of learning Manifold efficiently if we do not learn to make savvy use of Help facilities such as Contents, Index and Search.

Help - Manifold on the Web

The Help - Manifold on the Web menu launches an Internet browser session to connect to a variety of web sites of interest to Manifold users. You must have a functioning Internet connection and an installed Internet browser to use this capability.

Community The Manifold online community, the Georeference worldwide forum of Manifold users voluntarily participating in an Internet forum for discussion and mutual assistance.

Free Stuff The Free Stuff page on the manifold.net web site. A collection of free scripts and programming examples, including IMS example web sites.

News The News page on the manifold.net web site.

Online Support The Support page on the manifold.net web site, a useful first stop for general support information, service packs and other information of interest to technical support.

Manifold Home The manifold.net home page.

Note that Internet pages for the internal links in the Manifold on the Web menu are kept current for the duration of the current Manifold release. If the Manifold release covered by this documentation has been replaced by a newer release, the Internet pages may change.

The Manifold Online Community

The Community choice connects to the online Georeference forum at http://www.georeference.org run by Manifold users. Note that this is not a "factory" web site managed by manifold.net - it is simply an online meeting place where Manifold users from all over the world can meet to discuss Manifold System.

The Community forum can be a great place to discuss Manifold with your friends online, to give and to get technical assistance and to talk about new ideas for Manifold and for using Manifold. Experienced members of the Manifold online community offer the following advice when visiting the forum:

- People who read and make posts in the forum are ordinary users just like you. They all have their "day jobs" and are visiting the forum on their own time.
- There is a zero tolerance policy on insults, ad hominem attacks, foul language and other incivilities. Please keep it polite, respectful of other participants and professional. Be patient with beginners.
- If you need help using Manifold, don't be impatient to get answers to your postings. Remember, other people reading the forum are ordinary users just like you. If they have time and take an interest in helping you, they may post a reply. But any participation by anyone is completely voluntary. If you have a technical question and need a response for sure, see the Technical Support topic.
- People in the online Manifold community tend to be very generous with their time unless they feel they are being taken advantage of. Postings of the form "I don't have any time to learn about this... someone please do it for me" won't usually get many responses. In contrast, a posting that shows you have studied the documentation and have tried to work out a problem before raising it in the forum will usually get many responses from all over the world.
- When engaging someone in a discussion thread, do not email them directly unless invited to do so by that person. Any responses to postings in the forum should be made on the forum where everyone can read them and where people have a choice as to whether they want to respond or not.
- As in any community, your reputation in the community depends upon you. If you are courteous and knowledgeable and helpful you will find many supportive users who will reciprocate. Keep it clean and technical. Do not use profanity and do not engage in ad hominem attacks on others. If you find yourself commenting on someone else instead of on product technology, you are crossing the line.
- Keep in mind that users from all over the world participate in the online Manifold community and that English is not a first language for many participants. Sometimes it is helpful to use simple English and to avoid slang if a language gap arises.
- manifold.net does not moderate the forum nor monitor it for suggestions. If you have a suggestion to improve the product, read the Contacting manifold.net topic and then send your suggestions directly to manifold.net. Use the forum as a good place to discuss your ideas with other Manifold users so that when you send in your suggestion it is as strong as possible.
• Like any unmoderated, online community that anybody can join, although the forum has many well-informed users with expert skills it also has its share of self-appointed experts who have poor skills and a poor grasp of technology. The real experts will usually call out errors, but they cannot catch every error. Don't believe everything you read on this or any other forum. If you need authoritative information, hire an expert or utilize a manifold.net tech support service product.

• There may be people who are employed by manifold.net and who are active in the forum. If so, they are there on their own time as ordinary hobbyists with a personal interest in using Manifold. They are not paid to participate in the forum, so don't think they have any special obligations to answer questions or to provide a special communications channel to manifold.net. If anything, other members of the Manifold online community will be especially annoyed at newbies who pester any manifold.net employees on the forum because they know that is the surest way to drive such people off the forum. Postings from any manifold.net employees on the forum do not represent the views of manifold.net - only direct communications from manifold.net on the website should be taken as official information.

• The Manifold online community is for discussing Manifold products. It is not for gossip about Hollywood, current events or personalities, or for religious, political, financial, legal, medical or other off-topic posts. Do not post advertising or spam in the forum. Do not seek or give advice such as medical advice, legal advice or other regulated professional opinions or advice. For example, no essays about how to install water heaters in a way that hopefully will not electrocute anybody or gas the occupants of a dwelling. Please stick to technical discussions of Manifold products and reasonably closely associated other software technologies. Although the forum is not moderated, a blacklist mechanism provides a way of eliminating spammers, habitual rule violators, sociopaths or other folks who just can't stick to a productive, professional, courteous technical discussion of Manifold products.

• See the forum for updated guidelines and additional information.

Toolbars

Toolbars

Manifold duplicates many menu commands in the form of toolbar buttons. Buttons all have Tool Tips, which are quick labels that pop open if the mouse cursor lingers on the button. Toolbars may be turned ON and OFF under the Tools - Customize menu. A right mouse click on the main menu bar calls up a shortcut to the Tools - Customize menu.

Individual toolbars may be dragged to different locations on the display. They may be "docked" on any of the screen edges or left "floating" in the middle of the display. Move a docked toolbar by dragging the 3D ridge at the left or top of the toolbar. Move a floating toolbar as you would any window, by dragging its title bar. Use a CTRL-drag to drag a toolbar past the normally docked position. On exit, Manifold remembers how you left your toolbars positioned.

Manifold toolbar buttons are context sensitive and are not enabled unless they can be applied. For example, unless we are working on an image the Select Pixels selection mode button will not be enabled in the Selection toolbar.

Toolbars know what type of component is the active window and can be customized to provide a different set of buttons for different components. For example, the Shapes toolbar provides a different set of commands for drawings than it does when an image is the active window.

The toolbars are shown below in their undocked form. Toolbars may be undocked by dragging them (using the small 3D ridge at the left side or top of the toolbar) into the main Manifold window. In docked form, toolbars do not have a title bar.

To quickly see which toolbar is which, use Tools - Customize to turn it ON and OFF. As the toolbar turns ON and OFF it will be obvious which it is.
Alignment Toolbar - Aligns and sizes controls in forms and aligns objects in drawings.

Format toolbar - Controls the formatting in drawings, images and labels layers. The drawing version shown formats foreground/background color, pattern style and pattern size for areas, lines and points. The image and labels versions show foreground and background color, style and size.

Navigation toolbar - Zoom, center and pan functions.

Selection toolbar - Select objects and/or pixels. Shows selection mode, selection filter, mouse cursor method and choice of styles by which selection is shown.

Snap toolbar - Specifies snap modes for use in drawings. Snap to forces the motion of the mouse cursor to jump between allowed locations only.
Tools toolbar - Toolbox for creating objects in drawings, for painting into images or entry of text labels. The drawings and images forms of the toolbar are illustrated. This toolbar will change to suite whatever is the active type of component (that is, drawing or image or text label component).

Tools (Advanced) toolbar - Toolbars used with forms include the default Tools toolbar and the Tools (Advanced) toolbar. The Tools toolbar for frequently used controls is used with Forms to create Windows standard user interface controls. The toolbar is enabled when a Form is the active window. Forms are used to provide user interfaces to scripts, to view tables and for other functions within Manifold. Advanced controls are used with Forms to create Windows standard user interface controls. The toolbar is enabled when a Form is the active window. Forms are used to provide user interfaces to scripts, to view tables and for other functions within Manifold.

Tracing toolbar - Works within maps to create objects in drawings by automatically tracing over images. This function is called vectorizing in traditional GIS packages.

Transform toolbar - A toolbar loaded with operators that can accomplish "one step" editing and transformation of the contents of the active window. The transform toolbar's operators box will be loaded with the applicable operators for whatever type of window is active (drawing, image, etc.).

Tech Tip

The default installation of Manifold System contains the toolbars described in this documentation. If toolbars are missing or do not appear in the Tools - Customize dialog, check the Config folder within the Manifold System installation folder for an XML files that may have been added containing <addin> entries. An add-in may be used to add commands to Manifold and also to control the availability of toolbars.
Alignment Toolbar

The **Alignment toolbar** is most frequently used to neatly align controls such as text boxes and command buttons in forms. It can also neatly align objects in drawings. Finally, it is used to align elements in print layouts. When used with drawings, the alignment toolbar is most frequently used in CAD style drawings such as diagrams of office or factory layouts.

The alignment toolbar is turned off by default. To turn it on, open a component that uses the alignment toolbar (such as a layout), choose Tools - Customize and check the box for the alignment toolbar.

To use the alignment toolbar, click on the form or drawing that has objects to be aligned and then press the alignment control desired. If no selection is present, the alignment toolbar works on all objects. If a selection is present, the alignment command will apply only to the selected objects or controls.

Some alignment commands require a **primary** selected object that is taken as the reference point.

![Alignment Toolbar Image]

- **Align Left** - Move objects so their left edges are aligned to the left edge of the primary selected object.
- **Align Top** - Move objects so their top edges are aligned to the top edge of the primary selected object.
- **Align Right** - Move objects so their right edges are aligned to the right edge of the primary selected object.
- **Align Bottom** - Move objects so their bottom edges are aligned to the bottom edge of the primary selected object.
- **Center Horizontally** - Move objects so that their centroid is centered horizontally in the form. In a drawing, this centers the centroid within the bounding box of all objects in the drawing.
- **Center Vertically** - Move objects so that their centroid is centered vertically in the form. In a drawing, this centers the centroid within the bounding box of all objects in the drawing.
- **Space Across** - Space objects evenly across the form in a horizontal direction. In a drawing, this spaces the centroid of each object evenly across the bounding box of all objects in the drawing.
- **Space Down** - Space objects evenly up and down the form in a vertical direction. In a drawing, this spaces the centroid of each object evenly up and down the bounding box of all objects in the drawing.
- **Same Width** - Resize objects so that the width of all is the same as the width of the primary selected object.
- **Same Width (Max)** - Resize objects so that the width of all is the same as the width of the widest object.
- **Same Width (Min)** - Resize objects so that the width of all is the same as the width of the narrowest object.
- **Same Height** - Resize objects so that the height of all is the same as the height of the primary selected object.
- **Same Height (Max)** - Resize objects so that the height of all is the same as the height of the widest object.
all is the same as the height of the tallest object.

**Same Height (Min)** - Resize objects so that the height of all is the same as the height of the shortest object.

**Full Width** - In layouts, increase width of this element to the full page width, within borders. In drawings, increase width of objects to the full width of the bounding box of all objects.

**Full Height** - In layouts, increase height of this element to the full page height, within borders. In drawings, increase height of objects to the full height of the bounding box of all objects.

**Full Size** - In layouts, increase width and height of this element to the full page size, within borders. In drawings, use the size of the bounding box of all objects.

When using **Align Top** and **Align Bottom** it's easy to command the system to stack up all the objects on top of each other. Simply click and drag them to different positions.

**See Also**

See the Align Items in Layouts topic for an example of aligning text labels in a print layout.
Edit Toolbar

The Edit Toolbar provides commands used to edit objects in drawings. If not already displayed, the edit toolbar will appear when an object is selected for editing with a 
CTRL-ALT clicking the object.

The most frequently used edit toolbar commands have keyboard shortcuts that allow them to be toggled on, switched and toggled off with a single key when an object is selected for editing. Using the keyboard shortcuts will speed up work flow in many situations because the mouse cursor can be kept near the work while the keyboard is used to rapidly choose the command desired. For example, with an object selected pressing the A key (either uppercase or lowercase) chooses the Add Coordinate command. Pressing the D key will switch from Add Coordinate to the Delete Coordinate tool. Pressing the D key again will toggle the Delete Coordinate command off. Note that pressing the next command’s key will switch to that command without any need to first toggle off the previous command.

Edit Toolbar Commands Illustrated
The following sequence of illustrations show edit toolbar commands in action. Each is preceded by the toolbar icon and brief description. Illustrations show the action of the command in a simple situation so that the action is clear. Following is an enlarged view of the command’s toolbar icon with comments intended to help remember and recall the mnemonic nature of the icon. Illustrations use line objects. The same commands work areas as well.

**Add Coordinate (A)**

Add Coordinate (A) - Add a new coordinate wherever the tool is clicked, inserting the new coordinate into the segment nearest the clicked location.

Choosing this tool and then clicking near a segment of a selected object will add a new coordinate and edit handle to the object at the location of the click. Note that the coordinate is added not necessarily exactly on the segment, but at the location of the click. The click must be made close to the segment so that it is unambiguous to which segment the coordinate is to be added. If the coordinate is to be moved farther away from the previous segment, create it with a click, toggle the Add Coordinate command off and then drag the coordinate to the location desired.

The icon for this command shows a new coordinate (the black square) added and so the old line segment (the red segment) moves into the new black line shape.

**Add Coordinate on Segment**

3460
**Add Coordinate on Segment** - Add a new coordinate exactly on the segment nearest the clicked location.

This command is similar to the one above except that when clicking near a segment it creates the new coordinate exactly on the old segment at the location nearest the click. It is used in a variety of ways, including to provide specific targets for *Snap* modes or using *Snap* modes to add coordinates at intersections between objects.

The icon shows a new coordinate (the black square) added with no change in the line shape since the new coordinate is added exactly on an existing segment.

**Delete Coordinate (D)**

**Delete Coordinate (D)** - Delete the next clicked coordinate.
Clicking on a coordinate / edit handle with this tool deletes it, collapsing the two segments it separated into a single segment between adjacent surviving coordinates.

The icon shows the two line segments deleted (the red apex lines) when a coordinate at the apex is deleted. The result is the black line seen.

**Delete Coordinate / Split Branch**

Delete the next clicked coordinate together with both adjacent segments, treating the remnants to either side of the deleted segments as two branches. Enabled when there are sufficient coordinates so that deleting a coordinate can create two branches.

This tool is similar to the above, except when the clicked coordinate is deleted both the coordinate as well as the two adjacent segments are deleted, leaving a gap between what have become separate branches.
The icon shows the two line segments deleted (the red apex lines) when a coordinate at the apex is deleted, with no segment replacing them. The two black lines shown are the result.

**Split Branch**

Split Branch - Split the object into two branches at the next clicked coordinate.

Clicking this tool on a coordinate will split the object into two branches at that location. Note that there is no immediate difference in appearance, since the two objects are exactly coincident at their mutual ends at the clicked position, with no gap between them.

We can see this by **CTRL-SHIFT** clicking and dragging one of the branches to move it in its entirety to a slightly different position.
This shows that there really were two branches formed. In reality, we will often split an object into two branches not to simply move one of the branches but rather to delete one of the branches. This is faster than deleting many coordinates one by one to delete the undesired portion of the object.

The icon shows a gap where the branch is split at the apex to indicate it is split into two branches. Note that in reality no gap appears when one branch is split into two branches since the ends of both branches will be exactly coincident at the location of the split.

**Delete Branch**

- **Delete Branch** - Delete the clicked branch. Enabled when there is more than one branch.

Available only for objects consisting of more than one branch, click this tool on any coordinate of a branch to delete that branch.

The icon shows a red figure where the entire branch is deleted. Note that in reality if a line consists of a single branch this last branch cannot be deleted.

**Extend (E)**
Extend (E) - Extend the edited line to another line or area object, if by extending the last segment of the edited line it is possible to intersect the target object. Choose the tool, click the end of the line being edited and then click the object to which the line is to be extended.

We begin with a line selected that is to be extended so that it precisely meets the line to the upper right. We select the tool and click once on the line segment or end coordinate / edit handle of the line to be extended...

...and then we click on the line to which it is to be extended.

The last segment is extended in its current direction so that the last coordinate is precisely on the target line.
Note that this command does not "split" the target line. If we select the target line for editing, we can see that it consists of two coordinates. There was no new coordinate inserted at the intersection with the extended line.

The icon shows one line selected (with a black square) being extended to a more solid line that is also selected.

**Note:** Manifold provides a CTRL command to extend to the next intersection if the line already intersects the object. When using the **Extend** command, CTRL-clicking the object to which the line should be extended will extend the edited line to the next intersection with the object if the line already intersects the object.

**Leave (L)**

**Leave (L)** - Cut an edited object with another object, leaving the designated part. Choose the tool, click a location in the part of the edited object that is to be retained and then click the object to be used as a cutter.

Given a line selected for editing that is to be cut by a second line, we choose the tool and then we first click on the portion of the edited line to leave...
...and then we click on the cutting line.

The result is the edited line is cut by the cutter and any portion other the portion clicked is discarded.

The icon shows a cutting line cutting the selected line, leaving the portion originally clicked (with the black square) and deleting the portion in red on the other side of the cutter.

**Trim (T)**

Trim (T) - Cut an edited object with another object, trimming off the designated part. Choose the tool, click a location in the part of the edited object that is to be removed and then click the object to be used as a cutter.

To use Trim we first click on the portion of the edited line to be discarded, or trimmed...
...and then we click on the line to use as a cutter.

The portion of the edited line first clicked is removed, that is, trimmed.

The icon shows a cutting line cutting the selected line, deleting the portion originally clicked (with the black square and red line) and saving the portion in black on the other side of the cutter.

**Split (S)**

.Split (S) - Split an edited object with another object. Choose the tool and then click the object to be used as a cutter.

Given a line selected for editing that is intersected by some other line we click on the cutting line.
The line selected for editing is then split into two branches.

We can see it has been split into two branches because there are now two coincident terminal coordinate points located exactly at the location where the cutting line intersected the edited line.

The icon shows a black line being cut into two by a cutting line. Note that in reality a line split by a cutter will not have a gap at the location of the cut, since the ends of the two split pieces will be exactly coincident.

**Scroll Wheel**

When using a mouse with a scroll wheel we can use the scroll wheel to zoom in and out. This works even in the middle of commands such as the edit toolbar editing commands. By default the zoom will be centered on the mouse position. Holding the CTRL key while operating the scroll wheel will force the zoom to be near the center of the opened window.
Format Toolbar

Used with drawings or drawing layers in maps, the Format toolbar controls the color, style and size of areas, lines and points. Used with text components the Format toolbar controls the color and appearance of text labels in that layer. Used with images, the Format toolbar controls the color, style and size of painting tools. Note that the contents of this toolbar depend on what component window or map layer is active.

Images

The Format toolbar appears with images as a shortcut to settings in the Tool Properties pane. It is used to control the action of painting tools.

- **Foreground color** - The main color applied by the painting tool.
- **Background color** - Used with image editing effects where background color replaces some or all pixels.
- **Style** - Brush pattern or other tool style.
- **Size** - Size in pixels of the applied brush or other painting tool.

Drawings

- **Areas Format** - Foreground / background colors, Style and size for all areas in this drawing.
- **Area Borders Format** - Foreground / background colors, Style and size for all area borders in this drawing. While the 1/20th of a point value for border size works well for screen display it is wise to increase the thickness of area borders for printed materials since 1/20th of a point results in lines that are too thin for good visibility with most printers.
- **Lines Format** - Foreground / background colors, Style and size for all lines in this drawing.
- **Points Format** - Foreground / background colors, Style and size for all points in this drawing.

See the Formatting and Formatting Drawings topics for more information and detailed examples of use with drawings.

Themes
The format toolbar for themes appears the same as for drawings, except that any formatting characteristics that are inherited from a parent drawing or theme are shown with corner brackets. The first format toolbar illustrated above shows formatting for a theme that has no inherited characteristics and the second format toolbar illustrated above shows a theme in which all characteristics are inherited.

The above format comes from a theme in which all formatting characteristics for lines are inherited from a parent, while area and point formatting characteristics have been specified within the theme.

**Labels**

Formatting applied to a labels component (either in a labels window or in a labels layer in a map) applies throughout the entire component or layer.

**Font** - Choose a font from those installed on this Windows system.

**Size** - Font size.

**Bold** - Boldface the font.

**Italic** - Switch the font to italic (slanted) style.

**Underline** - Underline the font.

**Align Text Left** - Align text with an even left margin.

**Center Text** - Center each text line in the label.

**Align Text Right** - Align text with an even right margin.

**Label Foreground** - The color used for the body of text letters.

**Label Border** - The color used for borders in label styles that use borders.

**Label Background** - Used as fill color in label boxes, shadows and other complementary color.

**Style** - Label style.

**Label Rotation Angle** - Sets rotation of labels, either in fixed degrees or under the control of a field value.

**Align Left** - Place labels to left of tie points.
Center Horizontally - Center labels horizontally on tie points.

Align Right - Place labels to right of tie points.

Align Top - Place labels above tie points.

Center Vertically - Center labels vertically on tie points.

Align Bottom - Place labels below tie points.

Alignment controls (Align Text Left, Center Text, Align Text Right and Justify) format multiple-line text to left margin, centered or right margin in the text object box.

The other Align controls adjust the position of the label object box relative to the tie point for the label.

The left-center-right and top-center-bottom buttons can be combined, for example, to create a right-bottom alignment.

See the Labels topic for more on text labels.

Print Layouts - Text Boxes

Formatting applied to text box objects in a print layout applies to that object only. The text box must be selected for editing with a CTRL-ALT click to enable the format toolbar for that box.

Font - Choose a font from those installed on this Windows system.

Size - Font size.
**Bold** - Boldface the font.

**Italic** - Switch the font to italic (slanted) style.

**Underline** - Underline the font.

**Foreground color** - Used for body of letters.

**Background color** - Used as fill color in text box. Invisible color is used by default.

**Align Text Left** - Align text with an even left margin.

**Center Text** - Center each text line in the text box.

**Align Text Right** - Align text with an even right margin.

**Justify** - Align text with even left and right margins.

**Align Top** - Align text to top of text box.

**Center Vertically** - Center text vertically in text box.

**Align Bottom** - Align text to bottom of text box.

The **Align** and **Center** controls adjust the position of the text vertically and horizontally within the label box:
The left-center-right-justify and top-center-bottom buttons can be combined, for example, to create a right-bottom alignment.

If you are interrupted or must otherwise put this book down, you should take steps to renumber your current position in the text: count the words already read and jot the number in the margin. You can...

When only a few words are available, the Justify control does not create an elegant effect. It is much better if it has more words to work with on each line as seen above.
Navigation Toolbar

Use the buttons in the Navigation toolbar to zoom and pan within the drawing, image or map.

- **Back** - Go back one view in the current component window.
- **Forward** - Go forward one view in the current component window.
- **Zoom scale combo** - Choose a zoom scale from a variety of even zoom scales.
- **Zoom To Fit** - Zoom so that the component fits within the current window size.
- **Zoom In** - Magnify the view as if seen from a closer distance.
- **Zoom Out** - Reduce the view as if seen from farther away.
- **Zoom Box** - Zoom to the size of the cursor box drawn with the mouse.
- **Center Point** - Pan the view so that the spot clicked is centered.
- **Grabber** - Interactive pan: click and drag with the grabber hand. The scene will be panned so that the initial point is moved to the spot where the drag is released.
- **Tracker** - Provides interactive distance and area measurements. See the Tracker topic.

When zooming with images, zoom in and zoom out will zoom to discrete zoom levels. To zoom to a particular level, use the **View - Zoom To** menu command.

The **Back** and **Forward** buttons maintain a separate queue of views for each component window that is open.

Additional Mouse Buttons

Manifold component windows (such as a drawing, image or map window) will automatically work with standard commands issued by additional mouse buttons on mice so equipped, such as the IntelliMouse Explorer. For example, the fourth and fifth mouse buttons typically issue **Back** and **Forward** commands for views.
Query Toolbar
The Query toolbar provides fast selection in tables, drawings and drawing layers in maps using "one line" simple queries using data fields associated with objects.

Field box  Operator box  Value box
The Query toolbar consists of three boxes, from left to right: a field box, the operator box, and a value box. The example show selects all records where Place_name contains the string "DURANGO".

Field box
Also known as the column box. The field that will be queried. The illustration above shows that the Place_name field will be queried. The field box will show all fields available in the table, including intrinsic fields and any fields brought in via relations.

Operator box
The query operator to use. Press in the not button to the left of the operator box to use the "not" version of the operator. For example, pressing in the not button in the example above will find all records Not Equal to the given value.

Value box
The value to be used with the operator. Not all operators require values. For example, Median does not take a value in the value box.

We use dark blue, black, and violet bold face fonts in this topic to distinguish the three boxes to make examples and explanation more clear. In "real life," Manifold uses the same black font color in all three Query toolbar boxes.

To find objects or records using the query toolbar:

1. Open the drawing, table or map. If using a map, click on the drawing layer desired.
2. Choose the field to query in the field box.
3. Choose an operator in the operator box. Push in the not button if the "not" form of an operator is desired.
4. Provide a value in the operator box if one is required for the operator used.
5. Press Select.

All objects in a drawing or records in a table selected by the query will appear in red selection color.

Query Toolbar Operators

Operators are available depending upon the type of table column selected. For example, operators using tokens work only with text columns. Comparison operators such as Greater than will work with text, binary, coordinate system and geometry columns as well as with numeric columns. When used with non-numeric columns a comparison operator will compare data going byte-by-byte stopping on the first different pair of bytes.

Binary columns, coordinate system columns and geometry columns support Duplicates, Duplicates Except First, Equal To, Greater Or Equal To, Greater Than, Less Or Equal To, Less Than, Not Equal To, and Uniques operators.

Areas
Select records with geometry for area objects. Available for geometry columns.

Bottom
Find the lowest N values of the given field. For example, Bottom 5 will find records with the lowest five values of
the given field.

**Containing** Select records in which the given field contains the given string.

**Containing Match** Select records in which the given field contains the given regular expression.

**Containing Token** Select records in which the given field contains the given token. See the Transform - Using Tokens and Text Strings topic for information on tokens.

**Duplicates** Select records that contain duplicate values in the given field.

**Duplicates Except First** Select records that contain duplicate values in the given field, excluding the first record of each set of duplicates.

**Empty** Select records with empty values. Available for binary, coordinate system, geometry, text and URL columns.

**Ending with** Select records in which the given field ends in the given string.

**Ending with Match** Select records in which the given field ends in the given regular expression.

**Ending with Token** Select records in which the given field ends in the given token.

**Equal to** Select records in which the given field is equal to the given value.

**Greater than** Select records in which the given field is greater than the given value.

**Greater or Equal to** Select records in which the given field is greater than or equal to the given value.

**Less than** Select records in which the given field is less than the given value.

**Less or Equal to** Select records in which the given field is less than or equal to the given value.

**Lines** Select records with geometry for line objects. Available for geometry columns.

**Matching** Select records in which the given field matches the given regular expression.

**Maximum** Select records in which the given field is the maximum value of all values found in the table.

**Median** Select records in which the given field is the median value of all values found in the table.

**Minimum** Select records in which the given field is the minimum value of all values found in the table.

**Not Equal to** Select records in which the given field is not equal to the given value. Equivalent to pressing the *not* button and using Equal to.

**Points** Select records with geometry for point objects. Available for geometry columns.

**Sounding Like** Find records with strings that have similar pronunciation in English using the Soundex algorithm. For example, in the *Mexico_eg.mif* sample drawing selecting **Place_name Sounding Like doorangoh** will find the province of Durango.
Starting with  Select records in which the given field starts with the given string.

Starting with Match  Select records in which the given field starts with the given regular expression.

Starting with Token  Select records in which the given field starts with the given token.

Top  Find the highest N values of the given field. For example, Top 5 will find records with the highest five values of the given field.

Typical  Find records in which the value of the given field is within the given number of records of the median.

Uniques  Select all records for which the value of the given field is not duplicated in other records. Equivalent to using not with the Duplicates operator.

Examples

The following examples are based on the mexico_eg.mif sample drawing.

<table>
<thead>
<tr>
<th>Field</th>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Place_name</td>
<td>Sounding Like</td>
<td>doorangoh will select the province of Durango.</td>
</tr>
<tr>
<td>Area(I)</td>
<td>Top 5</td>
<td>will select the 5 largest areas.</td>
</tr>
<tr>
<td>Place_name</td>
<td>Duplicates</td>
<td>selects all area objects that have duplicate names. For example, there are three objects with a Place_name of CAMPECHE and two that are named SONORA. This is a fast way of finding area objects, such as provinces, that may be drawing using more than one area. This is typically done to show islands or other non-contiguous parts of a province, country, state or county.</td>
</tr>
</tbody>
</table>

Regular Expression Examples

The Matching, Containing Match, Ending with Match and Starting with Match operators use Visual Basic style regular expressions. Examples using mexico_eg.mif and the Place_name field would be:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Matching</td>
<td>DURANGO selects one record (&quot;DURANGO&quot;),</td>
</tr>
<tr>
<td>Matching</td>
<td>CHI.+ selects two records (&quot;CHIHUAHUA&quot; and &quot;CHIAPAS&quot;),</td>
</tr>
<tr>
<td>Matching</td>
<td>.+OR[AE].* selects three records (&quot;SONORA&quot;, &quot;SONORA&quot; and &quot;MORELOS&quot;),</td>
</tr>
<tr>
<td>Containing Match</td>
<td>C[PQR] selects one record (&quot;VERACRUZ&quot;),</td>
</tr>
<tr>
<td>Containing Match</td>
<td>[^ A-Z] selects one record (&quot;EDO. DE MEXICO&quot;),</td>
</tr>
<tr>
<td>Starting With Match</td>
<td>BA.+ selects four records (all starting with &quot;BAJA&quot;),</td>
</tr>
<tr>
<td>Starting With Match</td>
<td>BB.+ selects nothing,</td>
</tr>
<tr>
<td>Starting With Match</td>
<td>[F-H] selects three records (&quot;HIDALGO&quot;, &quot;GUANAJUATO&quot; and &quot;GUERRERO&quot;),</td>
</tr>
<tr>
<td>Ending With Match</td>
<td>&quot;...&quot; (a space followed by three periods without quotation marks) selects three records (&quot;BAJA CALIFORNIA SUR&quot;, &quot;QUINTANA ROO&quot; and another &quot;QUINTANA ROO&quot;).</td>
</tr>
</tbody>
</table>

Token Operator Examples
Operators such as **Containing**, **Ending with** or **Starting with Token** use "tokens" which are groups of characters set off by separator characters. **Tools - Options** allows specifying what characters should be considered to be separators.

Suppose we have a field in a table listing the following set of processors:

- AMD K6
- AMD Athlon
- Intel 486
- Intel 486SX
- Intel Pentium
- Intel PII
- Intel PIII

Examples of different operators and results would be:

- **Containing Token** PII selects "Intel PII".
- **Containing** PII selects "Intel PII" and "Intel PIII".
- **Containing Token** 486 selects "Intel 486".
- **Containing** 486 selects "Intel 486" and "Intel 486SX".

**Tech Tip**

Suppose we would like to select all records with a null value in a given field. That is, we want to find all records that don't have a value in that field. There are at least five methods of doing so using the query toolbar. In the examples that follow below, do not type the " quotation marks in the value box. The field **Name** will be searched and all records with non-empty values in **Name** will be selected.

Use a regular expression requiring non-empty text:

- **Name Matching** ".+" (period and plus sign in the value box)

Use a regular expression with the **NOT** button:

- **Name Not Matching** ".*" (period and asterisk in the value box)

A hack using the **Sounding Like** operator:

- **Name Sounding Like** " " (nothing in the value box)

A hack using the **Less Than** operator:

- **Name Sounding Like** " " (space character in the value box)

An elegant use of the **Minimum** operator:

- **Name Minimum**

**Themes and Toolbars**

**Themes** can be used in the query and Transform toolbars. Object sets defined on themes will always use the name of the theme's parent drawing. For example, if there are selected objects in a theme named T whose parent is a drawing named D the selection choice will appear in the query or transform toolbar boxes as **Selection in D**.
This is done so that it is immediately clear that modifying a theme will modify the parent drawing (and thus all other themes bound to that drawing).

See also

The transform toolbar is also used to make spatial selections using commands such as Select Touching or Select Contained within that work between sets of objects.
Selection Toolbar

The Selection toolbar provides controls for **Selection Modes**, **Selection Filters**, **Selection Methods** and **Selection Style**.

### Selection Modes

The selection mode buttons control how a new selection made with a selection tool is combined with any existing selection. One selection mode button is always pushed in.

- **Select Replace** - Replace the existing selection with whatever is now selected.
- **Select Add** - Add whatever is now selected to the existing selection.
- **Select Subtract** - Subtract whatever is now selected from the existing selection.
- **Select Invert** - Deselect whatever is now selected that was already in the existing selection and otherwise add what has just been selected.
- **Select Intersect** - Select only the region of overlap between what is specified by the tool and what is in the existing selection. If there is no overlap, nothing will be selected.

### Selection Filters

Choose the type of items that are to be selected by pushing the selection filter buttons for the desired types. The buttons above show selection enabled for points and disabled for areas, lines, pixels and text labels. If we drew a selection rectangle over a region in the map that contained all four types of items, only the points within the rectangle will be selected. Areas, lines and pixels within the rectangle will be ignored.

- **Select Areas** - Enable selection of areas by mouse selection tools.
- **Select Lines** - Enable selection of lines by mouse selection tools.
- **Select Points** - Enable selection of points by mouse selection tools.
- **Select Pixels** - Enable selection of pixels by mouse selection tools.
- **Select Text** - Enable selection of text labels by mouse selection tools

All four filter buttons may be used in maps. When working with drawings, the **Select Pixels** button will be disabled. When working with images, the **Select Areas**, **Select Lines** and **Select Points** buttons will be disabled.
disabled. When working with images, **Select Pixels** is always enabled and will be shown in a "forced" style that cannot be clicked out.

### Selection Methods

These selection tool buttons specify how the mouse is used to select items in view. Only those items enabled by the Selection Filter buttons will be selected. Some selection commands come in regular and on-center versions. See the Selection topic for illustrated examples of the difference between the on-center version and the regular version of the selection tools.

- **Select Touch** - Click to select pixels like the one clicked, give or take the tolerance that may be set in **Tools - Options**.
- **Select Shape** - Select objects within a region defined by a series of clicks followed by a right click.
- **Select Freeform** - Select objects within a region defined by clicking and dragging, followed by a right click.
- **Select Box** - Click and drag to select items within a rectangular selection box
- **Select Box on Center** - Click and drag open a selection box that’s always centered on the point of first click.
- **Select Circle** - Click and drag open a selection circle within the rectangle implied by the mouse motion.
- **Select Circle on Center** - Click and drag open a selection circle that’s always centered on the point of first click.
- **Select Ellipse** - Click and drag open a selection ellipse within the rectangle implied by the mouse motion.
- **Select Ellipse on Center** - Click and drag open a selection ellipse that’s always centered on the point of first click.

**SHIFT key**  Shifts selection to "open" mode. Selects all items any part of which is within the shape drawn with the mouse.

### Selection Style

- **Selection Filter** - Appears with tables. Show only selected records in the table.
- **Selection Style** - Change the selection style to a less intrusive pattern or color or other style. The pull-down arrow next to the **Use Selection Color** button opens a menu of possible selection styles.
- **Select None** - Deselect all items.

See the main Selection topic for more information and detailed examples.
Snap Toolbar

Checking a choice in the Edit - Snap To menu controls Snap modes, which work with mouse cursor motion. Snap modes force the mouse cursor to take effect only at those discrete, specified locations that are nearest to the mouse cursor's location. See the Edit - Snap To topic for details and examples.

The snap toolbar is turned off by default. To turn it on, open a component that uses the snap toolbar (such as a drawing), choose Tools - Customize and check the box for the snap toolbar.

Snap Modes in Drawings and Themes:

- **Graticule**
  - Snap to graticule intersections if View - Graticule is enabled.

- **Grid**
  - Snap to grid intersections, if View - Grid is enabled.

- **Areas**
  - Snap to the coordinates that define areas.

- **Lines**
  - Snap to the coordinates that define lines.

- **Points**
  - Snap to points.

- **Segments**
  - Snap to arbitrary locations on segments defining line or area objects.

- **Selection**
  - Snap only to those objects in the selection.
  - Requires snap to areas, lines or points to be enabled.

  **TAB**
  - Depressing the TAB key jumps the cursor immediately onto the snap reticule. This is used when we want the mouse cursor to jump immediately to the snap point without a mouse click.

  **Space Bar**
  - Depressing the space bar turns off snap temporarily until the space bar is pressed again.
  - This is very useful to temporarily turn snap off.

Snap Modes in Layouts:

- **Grid**
  - Snap to grid intersections, if View - Grid is enabled.

- **Elements**
  - Snap to the corners of an element.

  **TAB**
  - Depressing the TAB key jumps the cursor immediately onto the snap reticule. This is used when we want the mouse cursor to jump immediately to the snap point without a mouse click.

  **Space Bar**
  - Depressing the space bar turns off snap temporarily until the space bar is pressed again.
  - This is very useful to temporarily turn snap off.

Snap Modes in Images, Labels, Profiles and Surfaces:
Graticule  
Snap to graticule intersections if View - Graticule is enabled.

Grid  
Snap to grid intersections, if View - Grid is enabled.

TAB  
Depressing the TAB key jumps the cursor immediately onto the snap reticule. This is used when we want the mouse cursor to jump immediately to the snap point without a mouse click.

Space Bar  
Depressing the space bar turns off snap temporarily until the space bar is pressed again. This is very useful to temporarily turn snap off.

Changing Snap Action with TAB and Space Bar

TAB  
Depressing the TAB key jumps the cursor immediately onto the snap reticule. This is used when we want the mouse cursor to jump immediately to the snap point without a mouse click.

Space Bar  
Depressing the space bar turns off snap temporarily until the space bar is pressed again. This is very useful to temporarily turn snap off. When snap is turned off using the space bar the status bar will not show snap modes enabled.

Pressing the Tab key will cause the mouse cursor to jump immediately to the snap cursor.

Snap Tolerance

The Snap Tolerance parameter may be optionally specified in the Tool Properties pane to control how close the mouse must be to a snap item before a snap mode takes effect.

When a snap mode is on, the Snap Tolerance setting gives the distance in screen pixels or in physical units within which the cursor must be to a given snap item (such as a line when snapping to lines) before the cursor snaps to that item.

When the cursor is outside the snap tolerance range, snaps are not effective. Setting a small snap tolerance is therefore a good way of retaining the benefits of snap modes without having the snap cursor jump about in a disconcerting way if the mouse is nowhere near a snappable item.

Layer Snap Restrictions

Using Layer Restrictions a map layer can be made non-snappable. When a layer is so restricted, any snap modes will ignore items in that layer.

Editing with Snap
Editing Forms
Autocomplete with ALT
Tool Properties
Tools Toolbar
The commands in the Tools toolbar are used to insert new points, lines and areas into a drawing or to paint regions of pixels into images. Objects may be created "free hand" or pre-built shapes may be used. Note that the contents of this toolbar depend on what component window or map layer is active.

Drawings

The Tools toolbar for drawings hosts drawing editing tools. The difference between on-center and regular versions of these tools is exactly analogous to the difference between on-center and regular version of these tools used for images. See the Image Editing Tools topic for examples of the difference between regular and on-center versions of painting tools.

See the Adding Shapes topic for additional details and examples of working with drawings.
If Snap modes are not on, the ALT key toggles between non-center and on-center version of whatever tool is selected.

### Images

The Tools toolbar for images hosts painting tools. See the Image Editing Tools topic for examples of the difference between regular and on-center versions of painting tools.

- **Paint Areas**: A mode button: the selected tool will create filled regions of pixels.
- **Paint Lines**: A mode button: the selected tool will create lines.
- **Paint Points**: A mode button: the selected tool will create points where the mouse cursor changes direction on clicks.
- **Paint Area**: Paint pixels within the region clicked. Creates lines or points if shape modes so specify.
- **Paint Freeform**: Paint pixels within region about which the mouse is clicked and dragged.
- **Paint Line**: Paint a line defined by straight-line segments between clicks.
- **Paint Box**: Paint a rectangular box using a mouse click and a drag.
- **Paint Box on Center**: Paint a rectangular box centered on initial mouse click.
- **Paint Circle**: Paint a circle using a mouse click and a drag.
- **Paint Circle on Center**: Paint a circle centered on initial mouse click.
- **Paint Ellipse**: Paint an ellipse using a mouse click and a drag.
- **Paint Ellipse on Center**: Paint an ellipse centered on initial mouse click.
- **Brush**: Paint a dot with one click or a continuous line with a click and a drag.
- **Paint Bucket**: Click to fill a contiguous or enclosed region with color. Fills to a given threshold of color.
  - SHIFT click to pour into the given color in all regions of the image, even if not contiguous. Use this as a "replace color" operation.
  - CTRL click to replace colors within the threshold while retaining the same intensity.
  - CTRL and SHIFT may be combined to replace non-contiguous colors while retaining intensity.
- **Gradient**: Click, drag and release to create a color gradient between click point and release point.
- **Pick Color**: Click to pick the color at that location as the foreground color.
  - Shift click to pick the color at that location as the
background color.

See the Image Editing Tools topic for additional information on painting into images.

If Snap modes are not on, the ALT key toggles between non-center and on-center version of whatever tool is selected.

**Layouts**

**Insert Horizontal Line**  Create a horizontal line in the layout. Default line size is 1/20th of a point.

**Insert Vertical Line**  Create a vertical line in the layout. Default line size is 1/20th of a point.

**Insert Box**  Create a rectangular box with a click and a drag. Boxes have foreground and background color and line thickness that can be set by selecting the box and using the format toolbar. Default line size is 1/20th of a point.

**Insert Box on Center**  Create a rectangular box centered on initial mouse click. Default line size is 1/20th of a point.

**Insert Text**  Add a text box, such as a caption, copyright notice or title, to the layout. Click on the text box to select it and then use the format toolbar to format the text. Double-click a text box in the layout to edit the text it contains.

**Insert Legend**  Add a legend to the layout, based upon a component used in the layout.

**Insert North Arrow**  Add a North arrow to the layout, based upon a component used in the layout.

**Insert Scale Bar**  Add a scale bar to the layout, based upon a component used in the layout.

See the Layouts topic for additional information on creating and using layouts.

**Scripts**

Scripts provide programming instructions used to customize Manifold or to create new capabilities. See Programming Manifold and Scripts for an introduction to scripts.
If the Manifold Debugger is installed, when a script has the focus the tools toolbar will have debugger commands enabled. The debugger helps us develop and debug scripts in the scripting language of our choice. Commands will be enabled in the debugger toolbar as make sense given the execution state of the script.

- **Run**: Run a script.
- **Run under Debugger**: Run a script under control of the debugger.
- **Pause**: Pause execution of a script.
- **Stop**: Stop execution of a script.
- **Step Over**: Step over a routine.
- **Step Into**: Step into a routine.
- **Step Out**: Step out of a routine.

### Labels

The tools toolbar has three commands available when a labels component has the focus. These commands are used to manually add labels to an unbound labels component. An unbound labels component is one in which label text is not automatically created from fields for all objects in a parent drawing but rather a labels component in which labels are added manually. Labels components are normally used within maps so that when adding labels by hand there are other components visible (such as a drawing) to provide correct positioning context.

- **Insert Label**: Add a text label to the labels component.
- **Insert Line Label**: Add a text label aligned to the guideline composed of straight line segments that is drawn with the insert tool.
- **Insert Freeform Line Label**: Add a text label aligned to the freeform, curved guideline that is drawn with the insert tool.

See the Adding Text Labels topic for examples of the above.

### Forms

The **Tools toolbar** is used with Forms to create frequently used Windows standard user interface controls. The toolbar is enabled when a **Form** is the active window. Forms are used to provide user interfaces to scripts, to view tables and for other functions within Manifold.

Click on a control in the Tools toolbar and then click and drag in the Form window to insert the control in the form in the position and size indicated by the mouse click and drag. Forms are then customized using the **properties** for each control as well as the **View - Info Window** for the **Form**.

See the individual controls topics for details on each control.
Insert Check Box - Inserts check box controls.

Insert Option Button - Inserts option button controls. Only one option button in a group may be selected.

Insert Command Button - Inserts command button controls.

Insert Frame - Draws frame with caption. Frames are used to set off groups of controls, often option buttons.

Insert Text Box - Inserts text box. Also called an edit field or edit control. This control can display text entered by the programmer at design time or entered by the user or assigned to the control by other code at run time.

Insert Static Text Box - Add a customized text box.

Insert List Box - Inserts list box controls.

Insert Combo Box - Inserts combo box controls.

Insert Horizontal Scroll Bar - Inserts horizontal scroll bar controls.

Insert Vertical Scroll Bar - Inserts vertical scroll bar controls.

See the Tools (Advanced) Toolbar topic for additional controls used with forms.

Debugger

Layouts
Tools (Advanced) Toolbar

The **Tools (Advanced) toolbar** is used with **Forms** to create frequently used Windows standard user interface controls that are technically more advanced or less frequently used than those in the **Tools toolbar**. The toolbar is enabled when a **Form** is the active window. Forms are used to provide user interfaces to scripts, to view tables and for other functions within Manifold.

Click on a control in the Tools (Advanced) toolbar and then click and drag in the Form window to insert the control in the form in the position and size indicated by the mouse click and drag. Forms are then customized using the **properties** for each control as well as the **View - Info Window** for the **Form**.

See the individual controls topics for details on each control.

---

**Insert Animation** - Plays silent .avi files to create dialog effects like the sheet of paper that flies between folders in the Windows copy progress dialog. Can also play silent .avi files dropped onto the control. Manifold provides 19 cool Windows dialog .avi files to get started.

**Insert Chart** - Inserts a chart control.

**Insert Image List** - Contains a collection of images that can be used by other Windows Common Controls such as ListView, TreeView, TabStrip and Toolbar controls, as well as with other controls with a Picture property. Saves development time by maintaining all images in a standard, consistent catalog of images.

**Insert Image Combo Box** - Similar to standard combo but with ability to include pictures with each item in the list portion of the combo, with special facilities for list management.

**Insert Date / Time Picker** - Displays date and/or time info and provides an interface for modifying date and time. Dropdown menu provides a MonthView calendar.

**Insert Month View** - An easy way to view and set date information using a monthly calendar. Can select one or multiple dates or show up to 12 months at a time.

**Insert List View** - Displays data as ListItem objects with an optional icon. Four different views provide data as icons, small icons, a list or a report. A sophisticated control.

**Insert Progress Bar** - Create a progress bar display that can be used to show the progress of a process.

**Insert Masked Text Box** - Used to prompt users for input using a fixed format specified by a mask pattern, for example, a telephone number in a specified format. If a mask pattern is not used, this control behaves about the same as a standard text box.

**Insert Rich Text Box** - Allows entry and editing of text using advanced formatting features, such as paragraph formatting with left and right indents, hanging indents, bold and italic font and so on. Also supports object embedding using the OLEObjects collection. Write your own word processor or create elaborate forms for users.
Insert Slider - Insert a slider bar control that can be moved left and right.

Insert Tree View - Insert a hierarchical tree display. Designed to display data such as organization trees, entries in an index, files and directories on disk, etc.

Insert UpDown - Insert an increment/decrement control, also called spin buttons.

Insert Tab Strip - Insert a tabbed control where clicking on each tab brings it to the fore.

Insert Picture Clip - Displays graphics from bitmap, icon, metafile, JPEG or GIF files.

Insert Multimedia Control - Manages Media Control Interface (MCI) devices like sound boards, MIDI sequencers, CD-ROM drives, audio players, videodisc players, etc. Add voice note recording to your dialog, or play spoken announcements.

Insert Status Bar - Insert a status bar like those at the bottom of many program windows. Complete with a nearly infinite set of properties for the intrepid programmer.

Insert Tool Bar - Insert a toolbar at the top of the form that hosts buttons or other controls. Yet another control with a vast array of properties.

Insert Cool Bar - Requires installation of Internet Explorer 3.0 or greater. Provides a modern, "railbar" look and the ability to create (get this!) user configurable toolbars like those in IE.

Insert Common Dialog Control - Provides a standard set of Windows dialog boxes for opening and saving files and selecting colors and fonts. Can also display Help.

Insert System Info Control - Detects system events such as desktop resizing, resolution changes, time changes. Also provides operating system platform and version information and changes in AC/battery power status and Plug/Play hardware configuration. Used when writing applications for portable devices (GIS in the field) and for developing info for your tech support team.

Insert ActiveX Control - Insert any ActiveX control available on this system.

See Also

Tools Toolbar
Tracing Toolbar

The Tracing toolbar works within maps to create objects in drawings by automatically tracing over images. This function is called vectorizing in traditional GIS packages.

Tracing toolbar buttons are enabled when a drawing layer in a map is clicked. Tracing commands require both an image and a drawing layer in the map.

The Pick Color command in the Tools toolbar for images is also used with tracing to specify the tracing color. To specify a tracing color, switch to the image as the active layer, use the Pick Color command to choose the color as the foreground color, click into the foreground color well and use the More... option to specify that color as a custom color. Next, switch back to the drawing and click into the Tracing Color well, click into the More... option and choose the previously saved custom color. (Future editions of Manifold will add the Pick Color command directly to the Tracing toolbar to avoid this circuitous process.)
Transform Toolbar

The Transform toolbar is loaded with operators that can accomplish "one step" editing and transformation of the contents of the active window. The transform toolbar’s operators box will be loaded with the applicable operators for whatever type of window is active (drawing, image, etc.). The transform toolbar is also used to make spatial selections using commands such as Select Touching or Select Contained within that work between sets of objects.

Because transform operators are highly specific to the type of window that is active, the transform toolbar is covered in detail within topics for each different component that has transform toolbar operators:

- Transform Toolbar - Drawings
- Transform Toolbar - Images
- Transform Toolbar - Tables

The transform toolbar uses the same general interface in all cases. We can consider the transform toolbar for drawings as an example. The transform toolbar makes changes throughout the entire drawing using the specified operators. Transform operators can create new objects, delete objects, change objects (for example, splitting them) and select objects using various algorithms such as the location of a shortest path.

Target box  Operator box  Parameter box

The Transform toolbar consists of three boxes, from left to right: a target box, the operator box, and a parameter box.

- **Target box**  Also known as the scope box. The objects that will be affected, altered or which will control the operation. Choices in the target box will be [All Objects], [Selection] or the names of any saved selections that have been saved in the Selections pane. The illustration above shows that the operator will be applied to all objects in the drawing.

- **Operator box**  The function to be applied. The operator box is context sensitive and will show only those operations that make sense for drawings. The example shows we will add border buffer zones.

- **Parameter box**  The value to be used. Depending on the operator, this may be another object set or a value entered by the user. Many operators, such as Boundaries do not require a parameter. The parameter box will not be enabled for such operators. In the example above we use 10000 for the size of the border buffer zones, the size being specified in the native units of the drawing.

We use dark blue, black, and violet bold face fonts in this topic to distinguish the three boxes to make examples and explanation more clear. In "real life," Manifold uses the same black font color in all three Transform toolbar boxes.

Using the Transform toolbar

1. Click on the map layer or drawing that contains the target objects.
2. Make a selection if the operation is to be applied just to the selection.
3. Choose the desired operator in the operator box.
4. Choose or specify a value in the parameter box, if this operation requires it.
5. Press Apply.
6. Some operators create new objects. Any new objects created will be created in the active
drawing/layer and will now be the Selection. Move the Selection to a new layer/drawing if you wish to
keep these objects organized separately from the original objects in the drawing (almost always a
good idea).

Themes and Toolbars

Themes can be used in the Query and transform toolbars. Object sets defined on themes will always use the
name of the theme's parent drawing. For example, if there are selected objects in a theme named T whose
parent is a drawing named D the selection choice will appear in the query or transform toolbar boxes as
Selection in D.

This is done so that it is immediately clear that modifying a theme will modify the parent drawing (and thus all
other themes bound to that drawing).

Context Menus

Context Menus
Context menus pop open when we right click on an item in Manifold. They are called "context" menus because
what they show depends on the context of where the right click occurred.

Most controls and other items visible on-screen in Manifold have context menus. These range from the main
toolbar to tabs in maps to column heads and individual cells in tables.

Drawings - Context Menus
Labels Components - Context Menus
Maps - Context Menus
Tables - Context Menus

Project Pane

The project pane has three context menus, depending on whether we right click on an empty portion of the project
pane, whether we right click onto a folder or we right click onto a component in the project pane.

Right Click onto an empty portion of the project pane

- Paste  Paste Clipboard data as a new component.
- Paste As Like standard Windows Paste, but allows pasting into a
different type of component when feasible. For example, we might copy a geocoded table and paste it as a
drawing. Appropriate intermediate dialogs will be raised as necessary to accomplish the Paste As operation.
- Create Create a new component in the project from the standard
list of components available.

Right Click onto a folder
Delete  Delete the folder and all of its contents
Create  Create a new component within the folder from the standard list of components available in a project.
Rename  Rename the folder.
Properties  Show the properties of the folder such as the name and an editable Description field.

Right Click onto a component

Open  Open the component in a window. If it is already open, activate the opened window and move it above other open windows.
Open in New Window  Open the component in a window. If it is already open in a window, open it in a new window.
Open Data Source  Appears for components linked from an external data source. Opens the Database Console and connects to the component data source.
Run  Appears for executable components, such as scripts and queries. Run the component.
Run under Debugger  Appears for scripts when the debugger has been installed. Run the script under control of the debugger.
Cut  Copy the component to the Windows clipboard and then delete it from the project.
Copy  Copy the component to the Windows clipboard.
Paste  Enabled when the Windows clipboard has contents compatible with the project pane. Paste the contents of the Windows clipboard into the project. For example, if we copy an image in PhotoShop we can use Paste to create an image in the project pane using the contents of the Clipboard.
Paste As  Like Paste, but allows pasting into a different type of component when feasible. For example, we might copy a geocoded table and paste it as a drawing. Appropriate intermediate dialogs will be raised as necessary to accomplish the Paste As operation.
Delete  Delete the component.
Duplicate  Create a copy of the component in the project, using a similar name constructed by appending or iterating a number. For example, duplicating “Drawing 1” will result in a copy called “Drawing 2”.
Create  Create a new component in the project from the standard list of components available.
Share  Appears when Enterprise Edition is in use. Save a component into the Enterprise server. Use this command to load the Enterprise server with shared components.
Get Latest Version  Appears with Enterprise Edition. Fetches the latest version of a shared component. If we are working with a shared component and someone has checked out the component we are using and altered it, we can use Get Latest Version to fetch the latest version.
Check In  Appears with Enterprise Edition. Saves the edited version of a component back to the Enterprise server and makes the component read-only in our project. When we are
done editing a shared component we can **Check In** to save the changed version of the component to the Enterprise server. After we check in, any user getting that component will get the newly edited version.

**Check Out**

Appears with Enterprise Edition. Gets the latest version of a shared component and makes it editable exclusively by us. Only one user at a time can check out a component. Other users can still link the component, but they will not see any changes we make until we check in that component.

**Undo Check Out**

Appears with Enterprise Edition. Enabled if we have used **Check Out** to get a component for editing. Abandons any changes we have made to a shared component on our local system, gets the latest version from the server and makes it read-only.

**Cached**

Appears with Enterprise Edition. Shared components are cached by default. We can designate a component to be uncached by right clicking on a shared component in the project pane and choosing **Cached** from the pop-up context menu to toggle the check mark next to the **Cached** entry. Tool tips and the project pane status bar will show the cached/uncached status of each shared component. See the Cached and Uncached Components topic.

**Unshare**

Appears with Enterprise Edition. Convert a shared component into a local component. The data from the Enterprise server will be downloaded to the local project and all connection to the Enterprise server for this component will be ended.

**Refresh Data**

Refresh (update) the contents of linked components.

**Relink**

Relink a linked component that has been disconnected from its data source.

**Unlink**

Unlink a linked component to create a local component. Copies the data from the remote component into a local component in the project.

**Rename**

Change the name of the component. The Component Name dialog that pops up includes a checkbox to **Adjust names of dependent components**, which, if checked (the default), will automatically rename any subsidiary components. For example, if we rename a drawing called **Mexico Drawing** to **Central Mexico Drawing**, then the drawing's table that was originally called **Mexico Table** will automatically be renamed **Central Mexico Table**.

**Export**

Export the component to a file outside of Manifold.

**Print**

Print the component.

**Assign Projection**

Alter the projection assigned to a component without altering component data using the Edit - Assign Projection dialog.

**Change Projection**

Alter the projection of a component and re-project component data using the Edit - Change Projection dialog.

**Properties**

Show the properties of the component such as the name and an editable **Description** field.

**Tech Tip**

Components in the project pane may also be renamed by a “slow double-click” or by pressing the **F2** key. Press **Enter** to commit the renaming operation without renaming dependent components, or press **SHIFT-Enter** to
commit the renaming operation and to also adjust names of any dependent components as if the *Adjust names of dependent components* option in the *Component Name* dialog had been selected.

**See Also**

- Project Pane - Open Data Source
- Project Pane - Paste as Surface
- Project Pane - Paste as Drawing
Project Pane - Open Data Source
Right clicking a component that is linked from an external data source in the Project pane and then choosing Open Data Source will open the Database Console and connect to the component data source.

Opening a component linked from an external data source in its own window, and then choosing the Open Data Source command in the component menu (for example, choosing Drawing - Open Data Source when a linked drawing window is open) does the same thing.

See Also

Database Console
Project Pane - Paste as Drawing

The **Paste as Drawing** dialog appears when we copy a component and paste it as a drawing.

**Pasting Tables as Drawings**

- **Select All** - Paste all columns.
- **Select None** - Do not paste any columns except ID.
- **Select Inverse** - Do not paste all current Paste As columns and paste all other columns. A fast way to use all but one column: click **Select None**, specify a Paste As choice for the one column not desired and then click **Select Inverse**.

**X / longitude**
Choose which field in the table should be used for an X or longitude coordinate.

**Y / latitude**
Choose which field in the table should be used for a Y or latitude coordinate.

**Latitude / longitude coordinates**
Check if the values in the X / longitude and Y / latitude boxes are in degrees latitude and longitude. If this box is not checked the surface will be created in Orthographic projection treating the X and Y values as meter-based coordinates.

**Skip zero latitude / longitude records**
If checked, any records with a zero value in the latitude and longitude fields will not have an object created in the drawing. Checked by default. This is a safety measure so that when pasting geocoded tables that have zero values for latitude and longitude (and thus, are not really geocoded) spurious points will not be created for the zero valued records.
Project Pane - Paste as Surface

The Paste as Surface dialog appears when we copy a component and paste it as a surface.

**Pasting Images as Surfaces**

- **Take Z From**
  Specify the channel value that will be used for the elevation. An RGBA image, for example will offer Alpha, Red, Blue, Green or Intensity choices.

- **Minimum Z**
  What elevation the lowest pixel value corresponds to.

- **Maximum Z**
  What elevation the highest pixel value corresponds to.

- **(units box)**
  Units of measure to be used.

**Pasting Tables as Surfaces**

- **X / long**
  Choose which field in the table should be used for an X or longitude coordinate.

- **Y / lat**
  Choose which field in the table should be used for a Y or latitude coordinate.

- **Latitude / longitude coordinates**
  Check if the values in the X / long and Y / lat boxes are in degrees latitude and longitude. If this box is not checked the surface will be created in Orthographic projection treating the X and Y values as meter-based coordinates.

- **Height**
  Choose the field to be used for elevation values for the surface.

- **Type**
  The data type to use for elevation values in the surface. If the originating field is a different type, Manifold will convert to the given type when writing to the surface.

- **Margins**
  Margins in the specified unit of measure (shared with the Pixel Size combos) in X and Y directions that the surface should be extended beyond the bounding box of the objects or records being pasted to create the surface. This allows extending the created surface by some margins beyond the data being pasted to create the surface, allowing some interpolation at the edges for smoother edge effects in some cases. 0 by default.

- **Pixel Size**
  Size of pixels in the created surface, in the specified unit of measure.

- **Same size in X and Y direction**
  If checked (default), any edits in the X pixel size will also update the Y pixel size, for "square" pixels.

- **Method**
  Gravity, Kriging, Median-Polish Kriging, No Interpolation or Triangulation (flat). The type of interpolation algorithm (model) used to create the surface. Options other than Kriging will appear only if the optional Surface Tools extension has been installed.

- **Neighbors**
  Appears when using the Gravity, Kriging or Median-Polish Kriging method. The number of neighboring points to consider when making the interpolation. Manifold will automatically use all points as neighbors for interpolations up to 1000 points. Note that it is faster to use all points as neighbors up to 1000 points than it is to use some subset of points (such as, only...
990 neighbors out of 1000 points).

**Model**
Appears when using the Kriging or Median-Polish Kriging method.

*Auto* (default), Exponential, Gaussian, Linear, Power, Rational or Spherical interpolation models. The *Auto* setting allows Manifold to choose which of the interpolation models it thinks will work best in this case.

Linear, Power, Rational or Auto choices will appear only if the optional Surface Tools extension has been installed.

**Use only Voronoi neighbors**
Interpolate over each location using only those neighbors that would be adjacent in a Voronoi diagram. This helps achieve a balance between a too-smooth interpolation achieved with a high number of neighbors and a too-coarse interpolation achieved with a low number of neighbors. Using this option will increase processing time.

**Use radius**
Appears when using the Gravity, Kriging or Median-Polish Kriging method. The distance in the given units from any data point over which an interpolation can extend. Not checked by default to allow Manifold to choose the radius.

**Save error surface as**
Appears when using the Kriging or Median-Polish Kriging method. Allows saving of an error surface using the given numeric type.

**Set corner values to**
Appears when using the triangulation method. Optionally set the values in the corners of the computed surface to the given values. If this option is used, the entire surface (to the full rectangular extents) will be interpolated using the corner values as anchors. If this option is not used, those regions outside the convex hull of the existing data points will remain invisible.

**Pasting Drawings as Surfaces**

Pasting a drawing as a surface is similar to pasting a table as a surface except that there is no need to specify the fields to be used as latitude and longitude, since the coordinates of objects in the drawing are built into the geometry of the drawing.

Likewise, there is no need to specify whether the coordinates are latitude and longitude coordinates, since the coordinate system used by the drawing is also known. When pasting a drawing as a surface, the surface will inherit all projection parameters from the drawing.

When pasting a drawing as a surface, Manifold can use point and line objects to create a surface. Point objects are taken as point data from which the surface is interpolated. Line objects will have point data created at each coordinate ("inflection point") that defines the line.

**Height**
Choose the field to be used for elevation values for the surface.

**Type**
The data type to use for elevation values in the surface. If the originating field is a different type, Manifold will convert to the given type when writing to the surface.

**Margins**
Margins in the specified unit of measure (shared with the Pixel Size combos) in X and Y directions that the
- Surface should be extended beyond the bounding box of the objects or records being pasted to create the surface. This allows extending the created surface by some margins beyond the data being pasted to create the surface, allowing some interpolation at the edges for smoother edge effects in some cases. 0 by default.

**Pixel Size**  
Size of pixels in the created surface, in the specified unit of measure.

**Same size in X and Y direction**  
If checked (default), any edits in the X pixel size will also update the Y pixel size, for "square" pixels.

**Method**  
Gravity, Kriging, Median-Polish Kriging, No Interpolation or Triangulation (flat). The type of interpolation algorithm (model) used to create the surface. Options other than Kriging will appear only if the optional Surface Tools extension has been installed.

**Neighbors**  
Appears when using the Gravity, Kriging or Median-Polish Kriging method. The number of neighboring points to consider when making the interpolation. Manifold will automatically use all points as neighbors for interpolations up to 1000 points. Note that it is faster to use all points as neighbors up to 1000 points than it is to use some subset of points (such as, only 990 neighbors out of 1000 points).

**Model**  
Appears when using the Kriging or Median-Polish Kriging method. Choose Auto (default), Exponential, Gaussian, Linear, Power, Rational or Spherical interpolation models. The Auto setting allows Manifold to choose which of the interpolation models it thinks will work best in this case. Linear, Power, Rational or Auto choices will appear only if the optional Surface Tools extension has been installed.

**Use only Voronoi neighbors**  
Interpolate over each location using only those neighbors that would be adjacent in a Voronoi diagram. This helps achieve a balance between a too-smooth interpolation achieved with a high number of neighbors and a too-coarse interpolation achieved with a low number of neighbors. Using this option will increase processing time.

**Use radius**  
Appears when using the Gravity, Kriging or Median-Polish Kriging method. The distance in the given units from any data point over which an interpolation can extend. Not checked by default to allow Manifold to choose the radius.

**Save error surface as**  
Appears when using the Kriging or Median-Polish Kriging method. Allows saving of an error surface using the given numeric type.

**Set corner values to**  
Appears when using the triangulation method. Optionally set the values in the corners of the computed surface to the given values. If this option is used, the entire surface (to the full rectangular extents) will be interpolated using the corner values as anchors. If this option is not used, those regions outside the convex hull of the existing data points will remain invisible.

---

**Notes**
Images that represent raster data such as elevations, temperatures and other factors are often visualized as surfaces.

If a field named z, elevation, elev, e, height, hgt or h (case insensitive) exists in the drawing or table, Manifold will offer that by default as the field in the Height box. Files named longitude, latitude, lon, long, lat, x or y (case insensitive) will be offered as the X / long or Y / lat box fields by default.

Attempting to create a surface larger than 16 million pixels (4,000 x 4,000) will trigger a confirmation dialog that will ask "Surface size is (x dimension) x (y dimension) pixels. Paste anyway?"

The Paste as Surface dialog will automatically compute and display the dimensions and size of the surface that will be created. Surface sizes larger than gigabytes are displayed in terabytes ("Tbytes"), petabytes ("Pbytes") and exabytes ("Ebytes"), although as a practical matter on most computers such very large surfaces are too large to create or display due to a lack of free disk space or other limitations.

Using the No interpolation option when pasting a surface from a drawing or a table will result in a surface being created as a series of facets that are not interpolated between the exact location of the given data points. Rather than appearing smooth when zoomed in, the surface will appear pixilated.

After pasting a drawing or table as a surface, when the surface is opened the Notes pane will list the interpolation parameters that were used to create the surface.

<td>Orthogonalize</td>
<td>Move coordinates to orthogonal grid positions. Used to trim insignificant digits.</td>
</tr>
<tr>
<td>Segmentize</td>
<td>Add redundant coordinates to increase the number of coordinates used to define the object. See the Segmentization topic for discussion.</td>
</tr>
<tr>
<td>Simplify</td>
<td>Remove coordinates that define the object to simplify the shape of the object.</td>
</tr>
</tbody>
</table>
Center  Pan the view to center this object in the window.
Zoom  Zoom to fit this object.
Coordinates  Launches the Object Coordinates dialog to allow direct editing of the coordinates that comprise the object.
Fields  Launches the Object Fields dialog that shows any table fields associated with this object.

The **Cut**, **Copy** and **Delete** functions within the context menu of a drawing work slightly different than their equivalents found in the **Edit** menu. The **Edit** menu versions work with the selection. The context menu versions of these commands work on those that object that has been right clicked.

**Example**

Right click onto an area in the drawing and choose **Delete** from the context menu. The area will be deleted.

**Right Click onto an Object that has been Selected for Editing**

**CTRL-ALT** click on an object to select it for editing. Editing handles will appear at the coordinates that define the object. A right click on the object (either on a coordinate of the object or on a line segment between coordinates) calls up the following menu:

- **Cut**  Windows clipboard cut operation. Copies object to the clipboard and delete it from the drawing.
- **Copy**  Windows clipboard copy operation. Copies object onto the clipboard without deleting it.
- **Paste**  Paste the contents of the Windows clipboard into the drawing. Creates new objects in the drawing, replacing any objects that were selected. New objects will be selected.
- **Paste Append**  Like **Paste**, but does not delete and replace any objects that were previously selected.
- **Delete**  Permanently delete this object.
- **Branch**
  - **Delete**  - Delete this branch (not enabled if there is only one branch - use the regular **Delete** choice.)
  - **Duplicate**  - Duplicate this branch. Use with care, as it is easy to lose track of multiple branches if they are created on top of one another.
  - **Split**  - Enabled if clicked on a coordinate. Split the object into two branches at this coordinate.
- **Segment**
  - **Delete**  - Delete this segment. It is not possible to delete one of the last two segments of a line branch or one of the last three segments of an area branch.
  - **Delete / Split**  - Delete this segment splitting the branch it is in into two branches. Only available when editing a line object. It is not possible to split the branch by deleting its first or last segment.
- **Coordinate**
  - **Add**  - Add a new coordinate at the location clicked. Such a click will not likely be exactly on the line segment, as a click reasonably near a selected object will be interpreted as involving that line even if the click was not exactly on the line segment.
  - **Add on Segment**  - Add a new coordinate to the object exactly on the line segment nearest to the click.
  - **Add Mid-Segment**  - Add a new coordinate to the object exactly in the middle of the line segment nearest to the
click.

**Delete** - Delete this coordinate. It is not possible to delete one of the last two coordinates defining a branch of a line or one of the last three coordinates defining a branch of an area.

**Delete / Split Branch** - Delete this coordinate and split this branch into two branches at that location. Used with lines.

**Duplicate** - Duplicate this coordinate. Used with lines and areas. It is wise to immediately move the new coordinate / edit handle to avoid confusion that might be caused by coincident (redundant) coordinates.

**Duplicate**

**Orthogonalize** Move coordinates to orthogonal grid positions. Used to trim insignificant digits.

**Segmentize** Add redundant coordinates to increase the number of coordinates used to define the object. See the Segmentization topic for discussion.

**Simplify** Remove coordinates that define the object to simplify the shape of the object.

**Center** Pan the view to center this object in the window.

**Zoom** Zoom to fit this object.

**Coordinates** Launches the Object Coordinates dialog to allow direct editing of the coordinates that comprise the object.

**Fields** Launches the Object Fields dialog that shows any table fields associated with this object.

The **Cut**, **Copy** and **Delete** functions within the context menu of a drawing work slightly different than their equivalents found in the **Edit** menu. The **Edit** menu versions work with the selection. The context menu versions of these commands work on those that object that has been right clicked.
Drawings - Object Coordinates

The Object Coordinates dialog appears as the Coordinates choice in the context menu when we right click on an object in a drawing. The dialog allows direct editing of the coordinates that comprise the object.

Please read the Coordinates topic if you have not already done so. This topic describes how objects are defined by the coordinates that are used to draw them in a "connect the dots" fashion.

The Object Coordinates dialog displays the list of coordinates that define the object that was right clicked. Editing this list will change the shape and/or position of the object. A + sign in the first column indicates the beginning of each branch of an object.

- **New** - Create a new coordinate in the list that is a duplicate of the currently selected coordinate (lines and areas only).
- **New Branch** - Insert a new branch (lines and areas only). A branch is a separator between coordinate lists used to define complex objects such as areas that contain holes.
- **Break Branch** - Break branch at highlighted coordinate (lines only, disabled unless there are at least two points before and after highlighted coordinate).
- **Delete** - Removes highlighted coordinate (lines and areas only, disabled for area branches containing three points and line branches containing two points).
- **Delete Branch** - Delete highlighted branch (lines and areas only, disabled when there is only one branch left).
- **Move to Top** - Move highlighted coordinate to start of branch (lines and areas only, disabled when coordinate is already at start of branch).
- **Move Up** - Move highlighted coordinate one step up (lines and areas only, disabled when coordinate is already at start of branch).
- **Move Down** - Move highlighted coordinate one step down (lines and areas only, disabled when coordinate is already at end of branch).
- **Move to Bottom** - Move highlighted coordinate to end of branch (lines and areas only, disabled when coordinate is already at end of branch).
Native Coordinates - Switch between coordinates within the projection coordinate system native to the drawing and Latitude and Longitude values.

Copy - Copy the list of coordinates to the Windows Clipboard.

Print - Print the list of coordinates through the standard print dialog.

This dialog is most frequently used to adjust the position of a point. Because a point is defined by only one coordinate it is easy to open this dialog and to change the X / Longitude and Y / Latitude values for the point. The dialog is less frequently used to edit areas and lines since such objects in a geographic context may be defined by thousands of coordinates.

One usage for areas or lines is when we wish to draw simple areas and lines in exact positions on the map. For example, suppose we want to draw a rectangular area within a Latitude / Longitude projection map that extends from latitude 38 to latitude 39 and from longitude 100 to longitude 101. An easy way of doing this is to draw a rectangle that approximately covers this region using the Insert Box tool from the Tools toolbar. We can then right click on this rectangle, choose Coordinates and then use the Object Coordinates dialog to change the four coordinates that define the rectangle into the exact values we want for the corners of the rectangle.

Native Coordinates

Native coordinates are numbers stored within the drawing that Manifold uses internally as positional coordinates. These numbers are shown in the Object Coordinates dialog. They are also used in the X (I) and Y (I) intrinsic field columns.

Projected coordinates are native coordinates adjusted with the local scale and local offset parameters of the coordinate system (projection) in use. In many cases, projected coordinates are the same as native coordinates (because of the local scale and offset values) but sometimes they are different.

Tech Tip

The Object Coordinates dialog may be invoked by first selecting an object for editing using smart mouse. Right clicking on one of the edit handles and then choosing Coordinates from the context menu will launch the Object Coordinates dialog with that edit handle's coordinate already highlighted and in view. See the Editing Objects topic.

Notes

Technically speaking, each line in the list defining the object is a coordinate pair. It is Manifold jargon to use the word "coordinate" to mean the pair of X / Longitude and Y / Latitude coordinates.

It is not possible to use this dialog to delete the last three coordinates in an area, the last two coordinates in a line or the last coordinate defining a point. To delete objects, select them and use Edit - Delete.

In the example noted above, of creating a rectangle covering one degree of longitude and latitude, if we intend to use this rectangle in projected maps we should Segmentize it after editing it to our satisfaction in the Object Coordinates dialog.

Editing Objects
Drawings - Object Fields

The **Object Fields** dialog appears as the **Fields** choice in the context menu when we right click on an object in a drawing. The dialog shows any data fields for this object in tables associated with the drawing.

The **Object Fields** dialog will show all fields in the drawing’s table. In addition, it will show the system-generated intrinsic fields for that object if desired. The status bar at the bottom of the dialog will report how many fields are displayed out of all available.

Although the dialog will remember previous settings, the **Object Fields** dialog tries to make sure it shows at least some fields on startup, even if the various Show ... filters have been set so that all fields are hidden. First the Show Blanks filter will be turned on to show fields with blank values, then the Show Intrinsics mode and finally Show Read-Only fields.

The **Object Fields** dialog is called with pre-loaded values when Instant Data mode is on and a new object is created.

**Note:** if fields for more than one object are to be reviewed, the Info Pane is usually more efficient than using the **Object Fields** dialog.

**Tech Tip: Speed on Opening**

The first time the **Object Fields** dialog is opened it may open more slowly than when subsequently opened. The reason is that some intrinsic columns are computed the first time the dialog is opened but their values may be fetched from cache during subsequent opens.
Some intrinsic columns, for example, Area (I), take a long time to compute, so Manifold caches their values whenever possible. The first time we access such a column (say, by invoking the Object Fields dialog, which queries the value of each intrinsic column, even if the intrinsic columns are initially hidden), Manifold will do the necessary computations and will save the resulting values into cache. On subsequent accesses Manifold will not need to compute the intrinsic column but can simply use values already in cache.

**Tech Tip: Field Filtering**

The Object Fields dialog filters the columns it shows, choosing which fields are displayed based on the settings of the Show Blanks, Show Intrinsics and the Show Read-Only buttons. By default, the dialog does not show the intrinsic and read-only columns. Any changes made to the filter settings are saved within Manifold so double-clicking an object, changing filter settings, closing the dialog and double-clicking another object will use the filter settings saved from the previous time the dialog was launched.

An exception to this rule happen if the Object Fields dialog starts up with all columns hidden due to filter settings. In that case Manifold will alter filter settings to show at least some columns, since opening the dialog without any columns visible might confuse inexperienced users.

When choosing what columns to show in such cases, Manifold will first turn on display of columns with blank values. If no columns become visible, the system will turn on display of read-only columns and then finally, if necessary, intrinsic columns. Note that one result of this strategy to help new users is that double-clicking an object in a drawing linked from a table or a query will by default display non-intrinsic columns.

**Labels Components**

**Labels Components - Context Menus**

The labels component window has only one context menu, which appears when we right click onto any label.

**Right Click onto a Label**

- **Cut**
  Windows clipboard cut operation. Copies label to the clipboard and delete it from the labels component.

- **Copy**
  Windows clipboard copy operation. Copies label to the clipboard without deleting the label.

- **Paste**
  Paste the contents of the Windows clipboard into the labels component. Pastes labels in the labels component, replacing any labels that were selected. New labels will be selected.

- **Paste Append**
  Like Paste, but does not delete and replace any labels that were previously selected.

- **Delete**
  Permanently delete this label.

- **Edit**
  Edit label text.

- **Duplicate**
  Create a duplicate of this label in the same location and select it, replacing the selection. When using Duplicate it is a good idea to immediately move the duplicate label to some other position to avoid creating coincident labels.

- **Orthogonalize**
  Move coordinates to orthogonal grid positions. Used to trim insignificant digits.

- **Segmentize**
  Add redundant coordinates to increase the number of coordinates used to define the label. Enabled only for line labels. See the Segmentization topic for discussion.
Simplify

Remove coordinates that define the object to simplify the shape of the object. Enabled only for line labels.

Center

Center this label in the map.

Coordinates

Launches the Object Coordinates dialog to allow direct editing of the coordinates that comprise the label.

The Cut, Copy and Delete functions within the context menu of a labels component work slightly different than their equivalents found in the Edit menu. The Edit menu versions work with the selection. The context menu versions of these commands work on those that label that has been right clicked.

Right Click onto a Label that has been Selected for Editing

Right clicking on a label that has been selected for editing calls a context menu that contains editing commands. When right clicking on an editing handle on a label selected for editing, or onto a line segment between editing handles, the context menu will also include additional editing commands.

Duplicate

Duplicate the label. It is wise to immediately move the new label while it is selected. This avoids creating coincident labels that might later cause confusion.

Orthogonalize

Move coordinates to orthogonal grid positions. Used to trim insignificant digits.

Segmentize

Add redundant coordinates to increase the number of coordinates used to define the label. Enabled only for line labels. See the Segmentization topic for discussion.

Simplify

Remove coordinates that define the label to simplify the shape of the label. Enabled only for line labels.

Center

Pan the view to center this label in the window.

Coordinates

Launches the Object Coordinates dialog to allow direct editing of the coordinates that comprise the label.

Branch

Delete

Delete this branch. Not enabled unless there is more than one branch.

Duplicate

Duplicate this branch at exactly the same position. Use CTRL-SHIFT to drag to a different position the new branch that is thus created (which otherwise exactly overlies the previous branch).

Split

Split this branch into two branches at the clicked position.

Segment

Delete

Delete the line segment clicked along with the edit handle coordinates to either side of the segment. Not enabled if there is only one segment left.

Delete / Split Branch

Delete the line segment clicked along with the edit handles to the left and right and also split this branch into two branches at that location.

Coordinate

(Right clicking onto an edit handle)
Delete
Delete this coordinate. It is not possible to delete the last two coordinates defining a line label.

Delete / Split Branch
Delete this coordinate and also split this branch into two branches at that location.

Duplicate
Duplicate this coordinate. It is wise to immediately move the new coordinate/edit handle to avoid confusion that might be caused by coincident (redundant) coordinates.

Coordinate
(Right clicking onto a segment between edit handles)

Add
Add a new edit handle (coordinate) at the location clicked.

Add on Segment
Add a new edit handle (coordinate) on the existing line near the location clicked.

Add Mid-Segment
Add a new edit handle (coordinate) at the middle of the segment nearest to the location clicked.

Example
Right click onto an area in the labels component and choose Delete from the context menu. The area will be deleted.

Maps
Maps - Context Menus
The main context menu for maps appears when right clicking onto a layer tab. The drawing context menu appears when clicking onto an object in a drawing layer in a map.

Context Menu for Map Layer Tabs

Visible
Show or hide this layer.

Add
Add a new blank drawing, image or labels component using the map's projection, or launch the Layers dialog to add components from the project pane. The component will be added as a layer just above the active layer tab.

Cut
Windows clipboard cut operation. Copy objects or pixels to the clipboard and delete them from the drawing.

Copy
Windows clipboard copy operation. Copy objects or pixels from this layer onto the clipboard.

Paste
Paste the contents of the Windows clipboard into this layer replacing any selected items.

Paste Append
Paste the contents of the Windows clipboard into this layer.

Delete from Map
Delete this layer from the map. The component will continue to exist in the project pane and in any other maps in which it participates.

Duplicate
Make a copy of this component in the project pane and insert it in the map.

Open
Open this component in its own window. If it is already open in its own window, activate that window.
**Open in New Window**
Open this component in its own window. If it is already open in its own window, open it again in yet another window.

**Rename**
Rename this component.

**Order**
Move layer to top, up, down or to bottom of layer stack.

**Opacity**
Set the opacity of this layer. See the Layer Opacity topic and the note below regarding the Opacity dialog.

**Restrictions**
Specify if this layer allows clicking, editing or selecting using mouse commands. See the Layers pane topic for more information on layer restrictions.

**Center**
Center the active layer in the map window.

**Zoom**
Zoom to the active layer in the map window.

**Zoom to Selection**
Zoom to fit the selection in the active layer in the map window.

**Match**
Enabled for image or surface layers. Crop / expand / resample / re-project the active layer so that matches the image or surface specified. Often used to prepare an image so that it is the same size and coordinate system as an another for use as a mask or other purposes.

**Register**
Move and re-scale this drawing to specify its geographic location. A manual operation that is rarely used. See the Georegistration topic for easier methods.

**Project to Map**
Re-project this layer’s component to match the projection currently used in the map. This is a permanent alteration in the data. When re-projecting an image or a surface, this command will automatically use equal values for the X and Y local scale parameters, thus resulting in geographically "square" pixels.

**Transfer Heights**
Transfer height values from a surface to a drawing. Available only if the Surface Tools extension has been installed.

**Transfer Selection**
Transfer selections between components.

**Visible Area**
Compute area visible from one or more locations in a surface. Available only if the Surface Tools extension has been installed.

**Use Projection**
Apply the native projection of this component as the projection used by the map.

**Properties**
View the properties dialog for this layer.

---

**Right Click onto an Object (Drawing Layers)**

**Cut**
Windows clipboard cut operation. Copies object to the clipboard and delete it from the drawing.

**Copy**
Windows clipboard copy operation. Copies object onto the clipboard without deleting it.

**Paste**
Paste the contents of the Windows clipboard into the drawing. Creates new objects in the drawing, replacing any objects that were selected. New objects will be selected.

**Paste Append**
Like Paste, but does not delete and replace any objects that were previously selected.
Delete
Permanently delete this object.

Duplicate
Duplicate the object. It is wise to immediately move the new object while it is selected. This avoids creating coincident objects that might later cause confusion.

Orthogonalize
Move coordinates to orthogonal grid positions. Used to trim insignificant digits.

Segmentize
Add redundant coordinates to increase the number of coordinates used to define the object. See the Segmentization topic for discussion.

Simplify
Remove coordinates that define the object to simplify the shape of the object.

Center
Pan the view to center this object in the window.

Zoom
Zoom to fit this object.

Coordinates
Launches the Object Coordinates dialog to allow direct editing of the coordinates that comprise the object.

Fields
Launches the Object Fields dialog that shows any table fields associated with this object.

Opacity Dialog
An alternative to setting layer opacity via the % edit box in the Layers pane is to use the opacity dialog that pops up from the context menu for map layer tabs. Right click onto a layer tab and choose Opacity to open the dialog:

The opacity dialog allows interactive setting of transparency by moving a slider bar. Check the Preview box to see the effect in real time. We can also click into the edit box and change the opacity value number.

Nomenclature

Transparency and opacity are two terms that mean the same concept viewed from different directions. When something is completely opaque it is not at all transparent. When something is perfectly transparent it may be said to have zero percent opacity.

Which word is used depends on the discussion. When imagining layers stacked up above each other like transparent sheets it is conceptually clearer to use the word transparency. When discussing a specific percentage of light transmission to be applied via a slider bar in a dialog most applications use the word opacity.

The convention in the graphics arts editing software industry is to adjust layer opacity with controls that set a number from 0% to 100% opacity, so that an image with 100% will be fully opaque and not allow any view of an image underneath it. Manifold follows this convention. This convention persists in the graphics arts industry even though the technical implementation of transparency effects is done using an alpha channel within RGBA images where the higher the value of the alpha channel (from 0 to 255) the higher the transparency.

One therefore encounters the slight conceptual dissonance of increasing opacity with higher numbers (up to 100%) in dialogs and other user interfaces while the internal data sets use numbers (alpha channel values) in which opacity decreases with higher numbers. Since we rarely set alpha values by hand this is not so bad. Alpha values are normally set using various tools, such as erasers, or masks. In the case of masks, the darker the mask region the lower the alpha value is and thus the higher the opacity. From a casual conceptual view this is very acceptable because it leads to an effect where black regions of masks cause full opacity and white regions...
of masks cause full transparency. Since we are used to thinking of "white space" as being transparent this works well as a natural mnemonic for the effects of masks.
Maps - Register

The **Register** dialog appears when choosing **Register** from a layer tab context menu. Right click on a layer tab in a map and then choose **Register** to open this dialog.

The **Register** dialog allows us to move and rescale this drawing to specify its geographic location. It is a manual operation that is rarely used. On occasion, after using automated georegistration the **Registration** dialog will be used to "nudge" an image into slightly different alignment to suite the user's taste.

See the Georegistration topic for easier methods of georegistering images and drawings. See the Manual Georegistration topic for discussion of manual georegistration issues, including the use of the **Register** dialog.

---

**Register** dialog:

- **Local offset**: Shifted version of the external coordinate system peculiar to this component. Specifies shift in X (longitude) and Y (latitude) direction in the given units.
- **Local scale**: Scaled version of the external coordinate system peculiar to this component. Specifies scale factor to be applied to external coordinate system.
- **Preview**: Show effect of changes in the map window.

**Units box**: Choose the unit of measure. All "unprojected" maps are in Degrees, Arc Minutes or Arc Seconds. Most projected maps are in meters.

Changing the **Local scale** settings changes the scale of the component to make it bigger or smaller. Changing the **Local offset** moves the component horizontally or vertically. With great patience and conceptual understanding it is possible to use the **Register** dialog to move and re-scale overhead view images so they are aligned to drawings in Orthographic projection. A much better idea is to use Georegistration tools to do the job automatically.

The **Register** dialog is used occasionally to create special effects or other expert purposes. The following example shows one possible usage.

**Example: Create a "Drop Shadow"**

We can give our drawing layers a sense of three dimensionality using the following procedure.

**Step 1: Prepare a Map of Mexico**

- Import a drawing of Mexico. Apply a thematic format.
- Right click on the drawing in the project pane and choose **Copy**.
- Right click again in the project pane and choose **Paste As - Drawing**. This creates an exact copy of the drawing.
- Format the copy so it is black in both foreground and background colors.
- Create a map using **mexico** and the copy. Open the map.
The illustration shows the map window with the `mexico` layer above the copy.

If we double click on the `mexico` layer to turn it off we can see the copy underneath.

**Step 2: Use the Register Dialog**
Right click on the copy layer (the all-black copy of \textit{mexico}) and choose \texttt{Register}. Check the \texttt{Preview} box so we can see the action of the dialog. Click on the up spin button on \texttt{Local offset X}. This moves the \texttt{CopyOfmexico} layer to the right.
Click on the up spin button on **Local offset Y**. This moves the **CopyOfmexico** layer down. The result is what appears to be a shadow below the **mexico** layer. When we are happy with the effect we click **OK**.

**Variations**

The effect shown above is exaggerated. Smaller offsets in **Local offset** usually look better.
Combine this technique with other effects. The illustration above was created by making two more copies of the \textit{mexico} drawing and in both of them deleting all objects except the highlighted provinces. We see a map with four layers: the topmost two layers contain the two provinces with a "drop shadow." Below them is the \textit{mexico} layer at a 60\% Layer Opacity value.

\textbf{See Also}

\texttt{Edit - Change Projection} for more information on using offsets and their relationship to other projection parameters such as false easting and false northing.

\textbf{Tables}

\textbf{Tables - Context Menus}

Tables have several different context menus that appear. Right click onto column heads, a cell, or a record handle to see the relevant context menu.

\textbf{Context Menu for Column Heads}

\begin{verbatim}
<table>
<thead>
<tr>
<th>Company Name</th>
<th>Company Name</th>
<th>Company Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alfreds Furtikste</td>
<td>Ana Trujillo Emareda</td>
<td>Arto</td>
</tr>
<tr>
<td>Arto</td>
<td>Around the Horn</td>
<td>Berglunds snakklopp</td>
</tr>
<tr>
<td>Berglunds snakklopp</td>
<td>Around the Horn</td>
<td>Berglunds snakklopp</td>
</tr>
<tr>
<td>Chris</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
\end{verbatim}

A \textit{column} is a field in the database table. In the notes that follow, "column" is a synonym for "field." The context menu for columns appears when right clicking onto a column head.

\begin{itemize}
  \item \textbf{Add - Column} Add a new column to this table.
  \item \textbf{Add - Active Column} Add a column in which values are determined by the results of a script. See \texttt{Active Columns}.
\end{itemize}
| **Add - Rank Column** | Add a column used to rank records by the results of a Decision Support System query. See Rank Columns.
| **Edit** | Enabled for Active Columns and Rank Columns. Adjust the source of this column (script or criteria).
| **Edit Script** | Enabled for Active Columns. Edit the script associated with this column.
| **Flatten** | Enabled for Active Columns, Rank Columns and Relations. Convert the column to a regular column by using the current values in the cells.
| **Flatten All** | Convert all Active Columns, Rank Columns and Relations to regular columns by using the current values in the cells.
| **Recompute** | Recompute the values in an Active Column.
| **Cut** | Windows clipboard cut operation. Copy selected records to the clipboard and delete them from the table.
| **Copy** | Windows clipboard copy operation. Copy selected records from this table onto the clipboard.
| **Paste** | Paste the contents of the Windows clipboard into this table, replacing selected records.
| **Paste Append** | Paste the contents of the Windows clipboard into this table, appending them to the table.
| **Delete** | Permanently delete selected records from this table.
| **Rename** | Change the name of this column.
| **Transfer Rules** | Specify how the values in this column should be transferred in operations such those in the Spatial Overlay dialog.
| **Format** | Specify how values should appear in this column.
| **Width** | Specify the width of this column in pixels.
| **Hide** | Show or hide this column. To find hidden columns, use the View - Columns command in the main menu for tables.
| **Change Type** | Change the field type of this column. Note that not all field types may be freely converted. For example, the number 132 can be converted into a text string containing the characters "132", but the text value "Madrid" cannot be converted into a number.
| **Language** | Specify Windows code page to be used for this column. Different columns in the same table can use different code pages to support different languages. Enabled for ANSI text fields only.
| **Order** | Move the column to the top (leftmost position), up, down, or to the bottom (rightmost position) in the display.
| **Best Fit** | Arrange the width of this column so that the values in the database will fit in it without extra space.
| **Best Fit All** | Arrange the width of all columns so that the values in the database will fit in them without extra space.
| **Best Fit Titles** | Arrange the width of all columns so that the full text of all column head titles is visible.
Identity  Select the ID column to be used in tables created with queries that have more than one identity column. See the Queries Using Multiple Tables topic. Enabled in query tables.

Find  Find a particular value in this column. Regular expressions may be used to search for patterns.

Replace  Find and replace values in this column. Regular expressions may be used to search for patterns and to specify their replacements.

Context Menu for Cells

<table>
<thead>
<tr>
<th>Identifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cut</td>
<td>Windows clipboard cut operation. Copy this cell's value to the clipboard and delete it from the cell.</td>
</tr>
<tr>
<td>Copy</td>
<td>Windows clipboard copy operation. Copy this cell's value to the clipboard.</td>
</tr>
<tr>
<td>Paste</td>
<td>Paste the contents of the Windows clipboard into this cell, replacing the value it contains.</td>
</tr>
<tr>
<td>Paste Append</td>
<td>Paste the contents of the Windows clipboard into this cell, appending to the value in the cell.</td>
</tr>
<tr>
<td>Delete</td>
<td>Permanently delete the contents of this cell.</td>
</tr>
<tr>
<td>More Like</td>
<td>Open a dialog allowing optional controls over a &quot;more like this&quot; search that specifies how each column should be reckoned to find additional records that are &quot;like&quot; this one.</td>
</tr>
<tr>
<td>More Like This Cell</td>
<td>Automatically find and select records that have values &quot;like&quot; this cell in this column.</td>
</tr>
<tr>
<td>More Like This Cell (Sorted)</td>
<td>Automatically find and select records that have values &quot;like&quot; this cell in this column. Sort the table so that records that are most like the value in this cell are at the top of the table.</td>
</tr>
</tbody>
</table>

A cell is any row/column intersection in a table. It is the value of a particular column for a specific record. The context menu for cells appears when right clicking onto a cell.

Context Menu when Editing Cells

<table>
<thead>
<tr>
<th>Identifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALFKI</td>
<td>Alfreds Puterkste Maric</td>
</tr>
<tr>
<td>ANATR</td>
<td>Ana Trujillo Empareda... Ana'</td>
</tr>
<tr>
<td>ANTON</td>
<td>Antonio Moreno Tapia... Arto</td>
</tr>
<tr>
<td>AROUT</td>
<td>Around the Horn</td>
</tr>
<tr>
<td>BERGS</td>
<td>Berglund's Snabblöp Chris</td>
</tr>
<tr>
<td>BLAUS</td>
<td>Player See Cell stereotype User</td>
</tr>
</tbody>
</table>
Double-clicking into a cell opens it for editing. The usual Windows context menu selections for editing values will appear when right clicking into the cell being edited.

- **Undo**: Undo the last edit operation. Only possible until the cell is closed for editing with an ENTER or by clicking on a different cell.
- **Cut**: Windows clipboard cut operation. Copy the highlighted part of the value to the clipboard and delete it from the cell.
- **Copy**: Windows clipboard copy operation. Copy the highlighted part of the value to the clipboard.
- **Paste**: Paste the contents of the Windows clipboard into this cell, replacing any highlighted part of the value.
- **Delete**: Permanently delete the highlighted portion of the value.
- **Select All**: Highlight all of the cell's value.

### Context Menu for Records

<table>
<thead>
<tr>
<th>Customer ID</th>
<th>Company Name</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>BERGS</td>
<td>Berglund's snabblöp</td>
<td>Chris</td>
</tr>
<tr>
<td>FHANS</td>
<td>Birger Saas Dalskrog</td>
<td>Hans</td>
</tr>
</tbody>
</table>

A **record** is any row in a table. In tables associated with drawings, each record represents the data fields for one object (a point, line or area) in the drawing. The context menu for records appears when right clicking onto a record's handle in the left border of the table.

- **Cut**: Windows clipboard cut operation. Copy this record's values to the clipboard and delete it from the table.
- **Copy**: Windows clipboard copy operation. Copy this record's values to the clipboard.
- **Paste**: Paste the contents of the Windows clipboard into this record, replacing the values it contains.
- **Delete**: Permanently delete this record.
- **More Like**: Open a dialog allowing optional controls over a "more like this" search that specifies how each column should be reckoned to find additional records that are "like" this one.
- **More Like This Record**: Automatically find and select records that have values "like" this record in this column, using those columns that are displayed in the table.
- **More Like This Record (Sorted)**: Automatically find and select records that have values "like" this record in this column. Sort the table so that records that are most like this record are at the top of the table.
- **Coordinates**: In tables associated with drawings, show the coordinates that define the drawing object for this record.
See the More Like This topic for information on the More Like This commands and dialog.
SQL Reference Guide

SQL in Manifold System

Manifold System includes a full implementation of the database language SQL. SQL is a language used in querying, updating, and managing relational databases. SQL can be used to retrieve, sort, and filter specific data to be extracted from databases. The system includes Data Definition Language (DDL) and Data Manipulation Language (DML) components that are used to manipulate the structure of the database and the data it contains. The DDL and DML capabilities are often lumped together in the term “SQL.”

Manifold System's SQL is a new implementation of SQL created by the Manifold engineering team that is optimized for spatial operations within Manifold projects. For maximum compatibility within Microsoft operating systems, Manifold SQL is designed so that it can operate as a superset of Microsoft SQL as it occurs within Microsoft's "Jet" database engine. Manifold SQL can also operate in ANSI compatibility mode.

In addition to duplicating the behavior of Jet SQL or ANSI SQL, Manifold SQL provides numerous extensions, profoundly enhanced speed in spatial usage and much greater flexibility. For connection to external databases, Manifold System uses standard Microsoft interfaces, including OLE DB, ODBC and Jet, which then allows usage of the external, linked data within projects including operations with Manifold SQL. See the Comparison with Jet and Comparison with ANSI SQL topics for a list of similarities and differences.

At times it may be convenient to work with external databases without importing their tables or linking them into a Manifold System project. For example, we might wish to alter the database or to use SQL to create a subset of data that may then be imported or linked into Manifold System. In earlier times, one would have to fire up Access or Manifold Database Commander or some other database tool to pound the external database into the desired shape. With Manifold System, one may perform such external tasks from within Manifold with no need for any external tools.

Manifold SQL is a full-power SQL implemented with the very latest in computing technology. SQL is an immense language that embeds the collective experience of the finest minds in database languages over many years. If you are new to SQL, get a good introductory book on this industry standard language.

To find specific words, use the Index or Find tabs in the Help system. The SQL Reserved Words / Index topic provides a handy, alphabetized list of key words that may be used for browsing.

Some examples throughout this book are taken from the Microsoft sample database, Nwind.mdb, which is provided on the Manifold CD. This database is for all practical purposes identical to the Northwind.mdb sample database distributed with Microsoft Access and other Microsoft products, except that the Nwind.mdb database uses spaces in the names of some columns ("Order date") where Northwind.mdb does not ("OrderDate").

If we have Access installed on our machine, we have a copy of Northwind.mdb in the C:\Program Files\Microsoft Office\Office10\Samples folder. Use either Nwind.mdb or Northwind.mdb to follow along in the examples. To avoid confusion, both versions of this database are referred to in these examples as the "Northwind" sample database.

If you are working with a downloaded version of Manifold System, consult the manifold.net web site for URLs to download Nwind.mdb and other examples.

Manifold SQL and ANSI Syntax Option

Manifold's SQL is designed to be compatible with Microsoft SQL as implemented in the Microsoft "Jet" database engine. Manifold SQL is intended to be a superset of Jet SQL with features supporting ANSI SQL as well. SQL syntax as documented within the Microsoft Jet SQL Reference for Access 2000 is a practical approach to Manifold SQL.

Manifold SQL has also been extended with special functions to use the spatial and geocoding capabilities of Manifold. Note that the geocoding extensions to SQL will be available only if either the Manifold US street address geocoding database is installed or if Microsoft MapPoint has been installed. See the Spatial Extensions and Geocoding Extensions topics.

In addition to being Microsoft-like, Manifold's SQL engine may be switched into an alternate mode where it parses SQL queries using ANSI syntax. To do so, open the query and in the View - Properties dialog check the Use ANSI-compatible syntax box.
When the ANSI option is turned off (the default), line comments start after an apostrophe (‘) or double dashes (--) and the names of tables and columns can be enclosed in square brackets ([ ]), strings are enclosed in quotes (“”) and times are enclosed in hashes (#).

When the ANSI option is turned on, line comments start after double dashes (--) and the names of tables and columns can be enclosed in square brackets ([ ]), quotes (“” or backward apostrophes (`), strings are enclosed in apostrophes (’) and times are enclosed in hashes (#).

Note from the above that date literals, that is times, are always enclosed in hashes (#). This avoids any possible confusion with string literals regardless of whether the ANSI compatible option is off or on.

Clearly, the safest course given that users might change the settings is to use double dashes (--) to mark line comments and to enclose the names of tables and columns in square brackets ([ ]). The main difference between having the ANSI option off or on is that with it off strings are enclosed in quotes (“”) and with the ANSI option on strings are enclosed in apostrophes (’).

Notes

The idea of relational databases originated in a 1969 IBM research report written by Dr. E.F. "Ted" Codd, who invented the relational model of databases and introduced it to the world. SQL originated as SEQUEL (for "Structured English Query Language") in 1974 at the IBM San Jose Research Laboratory in a project led by Donald Chamberlin.

Just about everyone in computing thinks that "SQL" is an acronym for "Structured Query Language." That’s not true, despite the historical origin of the language, as the ANSI standard defining SQL officially names it "Database Language SQL." Experts will also point out that SQL is not structured, it is used for more purposes than just asking about things (the conventional meaning of the English word "query") and it is technically not a "language" in the Turing sense of the word.

According to ANSI, “SQL” should be pronounced by saying the letters as in “ess cue ell.” However, many people prefer to pronounce the term as the English word “sequel,” especially when referring to Microsoft’s SQL Server DBMS product since “sequel server” is more alliterative and easier to say than “ess cue ell server.” It is very common to use both pronunciations, even in the same sentence, as in “This ess-cue-ell works in Sequel Server but not in Oracle.”

When running SQL within Manifold queries, one is using the Manifold SQL engine. When executing SQL within the Database Console one is using whatever SQL is the native SQL of the external database system. One should be aware that SQL implementations in various database systems can contain bugs. For example, even a very well crafted SQL like Microsoft's Jet SQL contains bugs. If an SQL bug occurs within the Database Console, the bug should be tracked down with the vendor of the external database system being used.

The following list includes words reserved by Manifold System for use in SQL statements. See also the names of functions, which are reserved words, in the extensions topics and the Expressions topic.

Future editions of Manifold System could add to the list of the reserved words. Because of this, it is highly recommended that the names of tables or columns used in a query are enclosed in square brackets, so that the query continues to work even if a name of some table or column it refers to becomes a reserved word.

Data Types

Manifold SQL data types consist of several primary data types and several valid synonyms recognized for these data types.

The following table lists the primary data types. The synonyms are identified in the SQL Reserved Words / Index topic.

<table>
<thead>
<tr>
<th>Data type</th>
<th>Storage size</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BINARY</td>
<td>1 byte per character</td>
<td>Any type of data may be stored in a column of this type. No translation of the data (for example, to text) is made. How the data is input in a binary column dictates how it will appear as output.</td>
</tr>
<tr>
<td>BIT</td>
<td>1 byte</td>
<td>Yes and No values and columns that contain only one of two values.</td>
</tr>
<tr>
<td>BYTE</td>
<td>1 byte</td>
<td>An integer value between 0 and 255.</td>
</tr>
<tr>
<td>COORDSYS</td>
<td>variable</td>
<td>A coordinate system token.</td>
</tr>
<tr>
<td>CURRENCY</td>
<td>8 bytes</td>
<td>A scaled integer between -9.2E14 and 9.2E14.</td>
</tr>
<tr>
<td>DATETIME</td>
<td>16 bytes</td>
<td>A date or time value between the years 100 and 9999.</td>
</tr>
<tr>
<td>DOUBLE</td>
<td>8 bytes</td>
<td>A double-precision floating-point value with a range of -1.8E308 to 1.8E308</td>
</tr>
<tr>
<td>GEOM</td>
<td>variable</td>
<td>A geometric object, includes coordinate system data.</td>
</tr>
<tr>
<td>GEOMSDE</td>
<td>variable</td>
<td>A geometric object in ESRI ArcSDE format.</td>
</tr>
<tr>
<td>GEOMSHP</td>
<td>variable</td>
<td>A geometric object in ESRI SHP format (geodatabase).</td>
</tr>
<tr>
<td>GEOMWKB</td>
<td>variable</td>
<td>A geometric object in OGC WKB format.</td>
</tr>
<tr>
<td>LATITUDE</td>
<td>8 bytes</td>
<td>A double-precision floating-point latitude value.</td>
</tr>
<tr>
<td>LONG</td>
<td>4 bytes</td>
<td>A long integer between -2,147,483,648 and 2,147,483,647.</td>
</tr>
<tr>
<td>LONGITUDE</td>
<td>8 bytes</td>
<td>A double-precision floating-point longitude value.</td>
</tr>
<tr>
<td>SHORT</td>
<td>2 bytes</td>
<td>A short integer between -32,768 and 32,767.</td>
</tr>
<tr>
<td>SINGLE</td>
<td>4 bytes</td>
<td>A single-precision floating-point value with a range of -3.4E38 to 3.4E38.</td>
</tr>
<tr>
<td>TEXT</td>
<td>2 bytes per character (Unicode)</td>
<td>Zero to a maximum of 2 gigabytes.</td>
</tr>
</tbody>
</table>

Synonyms

The following table lists synonym names for the primary data types used in Manifold SQL:

<table>
<thead>
<tr>
<th>Synonym</th>
<th>Data Type</th>
</tr>
</thead>
</table>

String Literals

SQL is case insensitive for SQL itself but is case sensitive when evaluating string values. Suppose, for example, we have a query such as:

```
SELECT [F] FROM [Table] WHERE [F] = "13AF";
```

This query will return no results if the value in "F" is "13aF", because that is not the same as "13AF".

To normalize case, use the Transform toolbar Make Lower Case or Make Upper Case operators to force all values in the column to upper case or lower case. Alternatively, use a modified SELECT statement:

```
SELECT [F] FROM [Table] WHERE UCase([F]) = "13AF";
```

When comparing strings, SQL is sensitive to leading or trailing whitespace. "13AF " does not equal "13AF". To remove leading / trailing whitespace use the Transform toolbar Trim Left, Trim Right or Trim operators to eliminate leading, trailing or both leading and trailing whitespace. Alternatively, use a modified SELECT statement:

```
SELECT [F] FROM [Table] WHERE Trim([F]) = "13AF";
```

The strings are enclosed either in apostrophes (') or in quotes (") depending on whether the query is ANSI-compatible or not.

Date Literals

The date literals used in SQL must use either ANSI format (year-month-day hour:minute:second) or one of the formats mentioned in the Regional Options applet in the Windows Control Panel.

To find records dated July 10, 1992 on a machine with US regional options, use either of the following statements:

```
SELECT * FROM [Orders] WHERE [Shipped Date] = #92-7-10#;
SELECT * FROM [Orders] WHERE [Shipped Date] = #7/10/92#;
```
The dates are enclosed in hash signs (#). They can also be enclosed in apostrophes (') or in quotes (") depending on whether the query is ANSI-compatible or not.

Spatial Extensions

Manifold System provides additional functions within SQL for selecting objects in drawings based on their geometric properties. Manifold also includes SQL functions to manipulate geometry data saved within tables.

The following table lists available spatial functions. Functions are often employed with data in tables of type Geometry, Geometry (SDE), Geometry (SHP) or Geometry (WKB). Different geometry types have different limitations. For example, the Geometry (SDE) type does not distinguish between lines and areas and uses integer coordinate values, and none of the geometry types except Geometry stores coordinate system data.

See the Geometry in Tables and the Queries and Geoms topics for additional information on storing and using geometry in tables.

<table>
<thead>
<tr>
<th>Function</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>AddCoord(line, point)</td>
<td>Adds the given coordinate to the first branch of the given line and returns the result.</td>
</tr>
<tr>
<td>Adjacent(geom, geom)</td>
<td>Returns True if the objects share at least one common location, and all common locations shared by the objects lie on a boundary of both objects; otherwise returns False.</td>
</tr>
<tr>
<td>AllBranches(geom)</td>
<td>Works on geoms of the same type and creates a geom with all branches of all source geoms. An aggregate function.</td>
</tr>
<tr>
<td>AllCoords(geom)</td>
<td>Works on geoms of any type and creates a multipoint geom with all coordinates (inflection points) of all source geoms. An aggregate function.</td>
</tr>
<tr>
<td>Area(geom[, unit])</td>
<td>Returns the area of the object in the specified units.</td>
</tr>
<tr>
<td>AreaEarth(geom[, unit])</td>
<td>Returns the ellipsoidal area of the object in the specified metric units.</td>
</tr>
<tr>
<td>AssignCoordSys(geom, coordsys)</td>
<td>Assigns a coordinate system to a geom and returns the result.</td>
</tr>
<tr>
<td>BorderBuffer(geom, width[, unit])</td>
<td>Returns border buffer of specified width for given area.</td>
</tr>
<tr>
<td>Boundary(geom)</td>
<td>Returns boundary of given area.</td>
</tr>
<tr>
<td>BoundingBox(geom)</td>
<td>Returns bounding box of given geometric object.</td>

<td>Returns parts of given geometric object lying within clipping area.</td>
</tr>
<tr>
<td>ClipSubtract(geom, clipWith)</td>
<td>Returns parts of given geometric object lying outside clipping area.</td>
</tr>
<tr>
<td>Contains(geom, geom)</td>
<td>Returns True if the first object entirely contains the second object.</td>
</tr>
<tr>
<td>ConvexHull(geom)</td>
<td>Converts a line or a point to a point set.</td>
</tr>
<tr>
<td>ConvexParts(geom[, tolerance])</td>
<td>Decomposes given area to convex parts. The tolerance parameter is in the coordinate system units of the geom.</td>
</tr>
<tr>
<td>Coord(geom, index)</td>
<td>Returns coord (inflection point) of given geometric object with specified index.</td>
</tr>
<tr>
<td>CoordCount(geom)</td>
<td>Returns total number of coords (inflection points) in all branches of given geometric object.</td>
</tr>
<tr>
<td>Coords(geom)</td>
<td>Splits geometric object into coordinates. A split function.</td>
</tr>
<tr>
<td>CoordSys(system [AS COMPONENT])</td>
<td>Loads a coordinate system from a component or a preset.</td>
</tr>
<tr>
<td>CoordSysToWKT(coordsys)</td>
<td>Prints a coordinate system into a WKT (PRJ) string.</td>
</tr>
<tr>
<td>Distance(geom, geom[, unit])</td>
<td>Returns the distance between the two objects in the specified units.</td>
</tr>
<tr>
<td>DistanceEarth(geomA, geomB [, unit])</td>
<td>Returns ellipsoidal distance between given points.</td>
</tr>
<tr>
<td>EnclosingCircle(geom)</td>
<td>Returns minimum circle containing given geometric object.</td>
</tr>
<tr>
<td>EnclosingRectangle(geom)</td>
<td>Returns minimum rectangle containing given geometric object.</td>
</tr>
<tr>
<td>EndPoint(geom)</td>
<td>Returns last point in given line that contains one branch.</td>
</tr>
<tr>
<td>FlipHorizontally(geom)</td>
<td>Flips given geometric object horizontally and returns the result.</td>
</tr>
<tr>
<td>FlipVertically(geom)</td>
<td>Flips given geometric object vertically and returns the result.</td>
</tr>
<tr>
<td>GeomType(geom)</td>
<td>Returns type of given geometric object as a number.</td>
</tr>
<tr>
<td>InnerBuffer(geom, width[, unit])</td>
<td>Returns inner buffer of specified width for given area.</td>
</tr>
<tr>
<td>IntersectionPoint(line, lineOther)</td>
<td>Intersects given line with another geometric object by splitting it into branches at intersection points and returns the results.</td>
</tr>
<tr>
<td>Intersects(geom, geom)</td>
<td>For points, returns True if a point belongs to another object, otherwise returns False. For areas and lines, returns True if the objects share at least one common location that does not lie on a boundary of both objects and if neither object contains the other object; otherwise returns False.</td>
</tr>
</tbody>
</table>
IsArea(geom)  Returns True if the object is an area; otherwise returns False.

IsClosed(geom)  Returns True if given line is closed and False otherwise.

Islands(geom)  Splits area into islands. An island is a subarea which consists of an outer contour and zero or more inner contours (holes). A split function.

IsLine(geom)  Returns True if the object is a line; otherwise returns False.

IsPoint(geom)  Returns True if the object is a point; otherwise returns False.

IsRing(geom)  Returns True if given line is closed and contains one (and only one) branch with no self-intersections and False otherwise.

JoinLines(line, lineOther)  Joins two given lines and returns the result.

Length(geom[, unit])  Returns the length or the perimeter of the object in the specified units.

LengthEarth(geom[, unit])  Returns the ellipsoidal length or the perimeter of the object in the specified metric units.

LinePart(geom, f, t[, unit])  Returns that part of a line between specified distance limits on given line. Both distances are measured from the start of the line and continue between branches. f is the "from" distance and t is the "to" distance for the new line. Suppose we have a road that is 12 miles long. LinePart(0, 6, "mi") will return the first half of the road, and LinePart(12, 6, "mi") will return the second half of the road reversed in backward direction. If a unit is not specified, the default native unit of the geom is used.

LinePoint(geom, d[, unit])  Returns a point that lies at the specified distance on given line. The distance is measured from the start of line and continues between branches.

MaxX(geom)  Returns the maximum X value in the object's coordinates.

MaxY(geom)  Returns the maximum Y value in the object's coordinates.

MinX(geom)  Returns the minimum X value in the object's coordinates.

MinY(geom)  Returns the minimum Y value in the object's coordinates.

MoveHorizontally(geom, distance[, unit])  Moves given geometric object by specified distance horizontally and returns the result.

MoveVertically(geom, distance[, unit])  Moves given geometric object by specified distance vertically and returns the result.

NewLine(geom, geom[, geom ...])  Returns a line using two or more point geom arguments or two or more line geom arguments. The coordinate system of the line equals that of the first geom. If all of the arguments are point geoms, the result is a line with a single branch from the first point to the last. If all of the arguments are lines, the result is a line with multiple branches. Otherwise (for example, a mix of point and line geoms), the result is a NULL.

NewPoint(x, y)  Returns a point with given XY coordinates in default coordinate system.

NewPointLatLon(x, y)  Returns a point with given XY coordinates in lat/lon coordinate system.

Normalize(geom)  Normalizes metric of given geometric object and returns the result.
Project(geom, system)  Project given geometric object to another coordinate system.

RectHeight(geom[, unit]) Returns the height of the object bounding box in the specified units.

RectWidth(geom[, unit]) Returns the width of the object bounding box for the object in the specified units.

ReverseLine(geom) Reverses direction of all branches in given line and returns the result.

Rotate(geom, angle) Rotates given geometric object by specified amount of degrees and returns the result.

RotateAbout(geom, center, angle) Rotates given geometric object, geom, about another geometric object, the center, by specified amount in degrees in angle and returns the result. If the object given as the center is a line or area the centroid of the object will be used for the axis of rotation.

Scale(geom, factor) Scales given geometric object by specified factor and returns the result.

ScaleHorizontally(geom, factor) Scales given geometric object by specified factor horizontally and returns the result.

ScaleVertically(geom, factor) Scales given geometric object by specified factor vertically and returns the result.

Segments(geom, subsegments) Splits each segment in given line or area into specified number of subsegments and returns the result.

ShapeHull(geom, cells) Returns shape hull of given geometric object.

StartPoint(geom) Returns first point in given line that contains one branch.

Touches(geom, geom) Returns True if the objects share at least one common location; otherwise returns False.

Triangles(geom[, tolerance]) Returns a triangulation of the given area. The tolerance parameter is in the coordinate system units of the geom.

Triangulation(geom[, tolerance]) Returns areas in the triangulation of a point set. The tolerance parameter is in the coordinate system units of the geom. See the Transform - Triangulation topic for a discussion of triangulation.

TriangulationLines(geom[, tolerance]) Returns lines in the triangulation of a point set. The tolerance parameter is in the coordinate system units of the geom. See the Transform - Triangulation topic for a discussion of triangulation.

UnionAll(geom) Unions all areas. An aggregate function.

UnionAreas(geom, geom) Unions two given areas and returns the result.

Voronoii(geom[, tolerance]) Returns areas in the Voronoi diagram of a point set. The tolerance parameter is in the coordinate system units of the geom. See the Transform - Voronoi Operators topic for a discussion of Voronoi diagrams (also called Dirichlet or Thiessen tessellations by some cultures).

VoronoiiLines(geom[, tolerance]) Returns lines in the Voronoi diagram of a point set. The tolerance parameter is in the coordinate system units of the geom.

VoronoiiPoints(geom[, tolerance]) Returns points in the Voronoi diagram of a point set. The tolerance parameter is in the coordinate system units of the geom.

WKTTToCoordSys(wkt) Parses a WKT (PRJ) string into a coordinate system.
See the Expressions topic for additional SQL expressions.

**Aggregate Functions**

Queries can use the AllBranches, AllCoords and UnionAll aggregate functions to aggregate Geom columns.

Importing or linking a geom created by AllBranches creates one line, one area, or one or more points. Importing or linking a geom created by AllCoords creates one point at the location of the first coordinate. To import the value returned by AllCoords as a set of points, alter the query to split the composite value returned by AllCoords into a set of individual coordinates by using the SPLIT BY clause. Importing or linking a geom created by UnionAll creates one area. If none of the argument areas overlap, the area returned by UnionAll is the same as that returned by AllBranches.

**Split Functions**

Queries can use the Branches, Coords, and Islands split functions to split Geom columns. See the SPLIT BY clause topic for details.

- **Branches** outputs each branch of an input geometric object as a separate object.
- **Coords** outputs each coordinate of an input geometric object as a separate point object.
- **Islands** outputs each island of an input area as a separate area.

**Remarks**

- **Geom** arguments are either geometric objects of type Geometry or are object IDs.

  All spatial computations are done using the location precision parameter taken from the drawing of the first argument if it is an object ID, or the maximum possible precision if it is a geometric object.

  All spatial computations are done using the coordinate system of the first argument. Performing spatial computations using data in different coordinate systems will convert the data in the second and any subsequent arguments to the coordinate system of the first argument.

  Some functions, such as Area or Distance, allow specifying measurement units. When specified, a unit should be compatible with the coordinate system of the first argument, in that if the coordinate system is Latitude / Longitude the unit must be angular (degrees or other angular unit), and if the coordinate system is not Latitude / Longitude the unit must be metric.

  If the unit argument is omitted the functions will use the units specified in the coordinate system of the first argument adjusted with the values of the local scale parameters, the adjusted result being equivalent to the component's native unit. See the Appendices - Tables - Units topic for a list of standard units.

  When using buffer functions, the buffer distance used must be at least four times the size of the location precision factor. If precision has been set to 10 meters then the buffer distance must be larger than 40 meters.

**Examples**

See the Sql.map sample project in the Manifold CD's Examples\Help folder for a Manifold project that contains SQL examples like those below.

We have a drawing D and want to compute its bounding box. We can do this with the following query:

```
SELECT BoundingBox(AllCoords(Geom([ID]))) FROM [D];
```

We have a drawing D that contains road segments with each segment assigned a road name in a column called Name. We want to join segments for each road into a single line object. We can do this with the following query:
SELECT AllBranches(Geom([ID])), [Name] FROM [D] GROUP BY [Name];

For the examples below, suppose we have two drawings called "Restaurants" and "Metro Stations" that contain point objects, a "Roads" drawing that contains line objects, and a "Parks" drawing that contains area objects.

This example uses the \texttt{Area} function to select the two largest parks:

$$\text{SELECT TOP 2 [Park Name] FROM [Parks] ORDER BY Area([Parks].[ID]) DESC;}$$

This example uses the \texttt{Distance} function to select the nearest restaurant to each metro station:

$$\text{SELECT [Metro Station Name], (SELECT TOP 1 [Restaurant Name] FROM [Restaurants] ORDER BY Distance([Metro Stations].[ID], [Restaurants].[ID]) FROM [Metro Stations]);}$$

This example uses the \texttt{Contains} function to select all restaurants within parks:

$$\text{SELECT [Restaurant Name], [Park Name] FROM [Restaurants], [Parks] WHERE Contains([Parks].[ID], [Restaurants].[ID]);}$$

This example uses the \texttt{Intersects} function to select all roads that intersect parks:

$$\text{SELECT [Road Name], [Park Name] FROM [Roads], [Parks] WHERE Intersects([Roads].[ID], [Parks].[ID]);}$$

This example uses the \texttt{Intersects} function to select all roads that intersect other roads:

$$\text{SELECT [Roads].[Road Name], [Copy].[Road Name] FROM [Roads], [Roads] AS [Copy] WHERE [Roads].[ID] <> [Copy].[ID] AND Intersects([Roads].[ID], [Copy].[ID]);}$$

This example uses the \texttt{Adjacent} function to select all roads near a park that are close to a metro station:

$$\text{SELECT [Road Name] FROM [Roads] WHERE EXISTS (SELECT * FROM [Parks] WHERE Adjacent([Parks].[ID], [Roads].[ID])) AND EXISTS (SELECT * FROM [Metro Stations] WHERE Distance([Metro Stations].[ID], [Roads].[ID], "yd") < 200);}$$

Suppose we have two drawings containing points where each point represents a ship. Each point has a "Ship ID" column that specifies the identifying number of the ship. Drawing "Monday" shows the positions of the ships on Monday and drawing "Tuesday" shows the positions of the ships on Tuesday. We would like to create a table that shows the distance between the Monday position and the Tuesday position for each ship.

$$\text{SELECT [Monday].*, Distance([Monday].[ID], [Tuesday].[ID], "km") AS [Sail Distance] FROM [Monday] INNER JOIN [Tuesday] ON [Monday].[Ship ID] = [Tuesday].[Ship ID];}$$

This will create a table with all columns from the "Monday" drawing plus a computed column called "Sail Distance" containing the distance in kilometers between ship positions on Monday and Tuesday. \texttt{Monday} must be a projected drawing to use the optional "km" specification of units. The objects in the \texttt{Tuesday} drawing will be reprojected on the fly, if necessary, into the coordinate system of the \texttt{Monday} drawing so that the same units can be used in both for the purposes of the query.

\textbf{Advanced Example}

This example shows three queries that do the same thing with greatly different performance. This illustrates the importance of considering different SQL approaches to achieve performance gains. The queries operate on a
project containing a surface, \(S\), and a drawing, \(D\). The drawing has lines in it, and our task is to select all pixels in the surface that are in a buffer zone within 20 units of a line in the drawing.

**Query 1** below is very slow because it re-computes the buffer returned by the inner SELECT for each pixel. The Manifold query engine is smart enough to cache the selected lines the SELECT operates upon, but it is not smart enough to cache the result of the aggregate on these lines. The solution is to get rid of computations in the column list of the SELECT (as is done in **Query 2**), or, better yet, to get rid of the SELECT in favor of a JOIN (as is done in **Query 3**).

The number of seconds cited for query execution of each query use a sample set of data that provides a reasonable comparison of the efficiency of the three queries.

**Query 1** - Approximately 2500 seconds:

```sql
UPDATE [S] SET [Selection (I)] = True
WHERE Intersects(SELECT Buffer(AllBranches([ID]), 20) FROM [D],
    NewPointLatLon([S].[Longitude (I)], [S].[Latitude (I)]))
```

**Query 2** - Computations in the column list are reduced to a minimum - 29 seconds:

```sql
UPDATE [S] SET [Selection (I)] = True
WHERE (SELECT Min(Distance([ID], NewPointLatLon([S].[Longitude (I)], [S].[Latitude (I)]))) FROM [D]) <= 20
```

**Query 3** - SELECT is replaced with an INNER JOIN - 3 seconds:

```sql
UPDATE (SELECT [S].[Selection (I)] FROM [S] INNER JOIN [D] ON Distance([D].[ID], NewPointLatLon([S].[Longitude (I)], [S].[Latitude (I)])) <= 20) SET [Selection (I)] = True
```

Reducing the time required for the query from 2500 to 3 seconds is a huge gain, certainly worth the time spent learning constructs such as INNER JOIN.

**Examples of Queries using Geometry Data**

Geocoding Extensions

Geocoding extensions operate with Manifold's geocoding engine to perform spatial operations based upon an address string or zip code.

Geocoding extensions will not work unless the optional Geocoding Tools package has been installed and also an appropriate geocoding database has been installed. See the Street Address Geocoding topic for information on geocoding databases that may be used.

Geocoding extensions using the Manifold US streets geocoding database will not work with Manifold IMS unless the geocoding database is installed within the Manifold application installation folder as specified in the Tools - Options file locations settings and as also specified within the IMS config.txt settings.

The following table lists available geocoding functions:

<table>
<thead>
<tr>
<th>Function</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>CloseToAddress(geom, address, distance[, unit])</td>
<td>Returns True if the object lies within the specified distance of the address; otherwise returns False.</td>
</tr>
<tr>
<td>CloseToZip(geom, zip, distance[, unit])</td>
<td>Returns True if the object lies within the specified distance of the zip code centroid; otherwise returns False.</td>
</tr>
<tr>
<td>DistanceToAddress(geom, address[, unit])</td>
<td>Returns the distance between the object and the address in the specified units.</td>
</tr>
<tr>
<td>DistanceToZip(geom, zip[, unit])</td>
<td>Returns the distance between the object and the address in the specified units.</td>
</tr>
<tr>
<td>LocateAddress(address)</td>
<td>Returns the location of the address as a point.</td>
</tr>
<tr>
<td>LocateAddressLat(address)</td>
<td>Returns the latitude of the address.</td>
</tr>
<tr>
<td>LocateAddressLon(address)</td>
<td>Returns the longitude of the address.</td>
</tr>
<tr>
<td>LocateZip(zip)</td>
<td>Returns the location of the zip code centroid as a point.</td>
</tr>
<tr>
<td>LocateZipLat(zip)</td>
<td>Returns the latitude of the zip code centroid. Works only with US zip codes.</td>
</tr>
<tr>
<td>LocateZipLon(zip)</td>
<td>Returns the longitude of the zip code centroid. Works only with US zip codes.</td>
</tr>
</tbody>
</table>

Remarks

Geom arguments are either geometric objects of type Geometry or are object IDs. The address and zip arguments are strings.

If an object is a line or an area the object's centroid is used for distance calculations.

If an address string produces more than one match, the system automatically selects the closest of the building-level matches (possibly with an "unknown street name, possible misspelling" error). If an address string produces no building-level matches, CloseToAddress returns False, and DistanceToAddress, LocateAddress, LocateAddressLat and LocateAddressLon return a null value.

If a zip code string is invalid (no matches in the geocoding database) CloseToZip returns False, and DistanceToZip, LocateZip, LocateZipLat and LocateZipLon return a null value.

If the optional distance unit is omitted, the system will use the native measurement unit of the drawing or meters if the drawing is not projected. See the Appendices - Tables - Units topic for a list of standard units.

Distances are great circle distances computed over a WGS84 ellipsoid and are accurate to 1 meter.
The geocoding functions cache returned geocoding data between subsequent calls. This means that a \texttt{LocateAddressLat} followed by a \texttt{LocateAddressLon} runs a geocoder search only once on the address.

Functions can be used from IMS as long as the geocoding database is located within the Manifold application installation folder (usually \texttt{C:\Program Files\Manifold System}). To keep the user interface simple and to avoid the complication of dealing with possible user errors when entering address information into forms, many web applications with IMS will use the \texttt{CloseToZip} or \texttt{DistanceToZip} functions since these require the user to merely enter the ZIP code correctly. For many applications, such as locating a dealer, finding the closest objects to the ZIP centroid provides acceptable accuracy.

**Examples**

For the examples below, suppose we have two drawings called "Clients" and "Dealers" that contain point objects and the "Clients" drawing that contains a zip code column.

This example uses the \texttt{CloseToAddress} function to locate all dealers within 10 miles of 330 Lytton Ave, Palo Alto:

\begin{verbatim}
SELECT * FROM [Dealers] WHERE CloseToAddress([ID], "330 Lytton Ave, Palo Alto, CA, 94301", 10, "mi");
\end{verbatim}

This example uses the \texttt{CloseToZip} function to select all dealers within 10 miles of the centroid for the 89701 zip code:

\begin{verbatim}
SELECT * FROM [Dealers] WHERE CloseToZip([ID], "89701", 10, "mi");
\end{verbatim}

This example uses the \texttt{DistanceToZip} function to select all dealers within 5 to 15 miles of the centroid for the 89701 zip code:

\begin{verbatim}
SELECT * FROM [Dealers] WHERE DistanceToZip([ID], "89701", "mi") BETWEEN 5 AND 15;
\end{verbatim}

This example uses the \texttt{LocateZipLat} and \texttt{LocateZipLon} functions to output a lat/lon location for the zip code centroid of each client:

\begin{verbatim}
SELECT [Name], LocateZipLat([Zip]) AS [Latitude], LocateZipLon([Zip]) AS [Longitude] FROM [Clients];
\end{verbatim}

Raster Extensions
## Raster Extensions

A raster data set is one in which data is stored as pixels arranged in rows of specified width. Images and surfaces are raster data sets within Manifold System. Manifold SQL provides functions for analyzing and manipulating raster data in images and surfaces. Note that some functions are available only if the optional Surface Tools extension is installed.

The following table lists available raster functions. Functions are often employed with data in tables of type `Geometry`, `Geometry (SHP)` or `Geometry (WKB)`. See the Geometry in Tables and the Queries and Geoms topics for additional information on storing and using geometry in tables.

In the following functions, `p` is either an image or surface (a raster data set consisting of pixels). `s` is a surface. `i` is an image. `g` is a geom.

<table>
<thead>
<tr>
<th>Function</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>AspectHeight(s, g)</td>
<td>Returns the aspect of s at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. Surface Tools only.</td>
</tr>
<tr>
<td>AspectHeight(s, x, y)</td>
<td></td>
</tr>
<tr>
<td>AspectHeight(s, x, y, w)</td>
<td>Passing the w parameter computes aspect over a window of specified size (1 for 3x3, 2 for 5x5, etc).</td>
</tr>
<tr>
<td>Blur(p, g)</td>
<td>Returns the value of the Blur filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.</td>

</tbody>
</table>
DifferenceSW(p, g)
- Returns the value of the DifferenceSW filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

DifferenceSW(p, x, y)

DifferenceSWHeight(s, g)

DifferenceSWHeight(s, x, y)

DifferenceW(p, g)
- Returns the value of the DifferenceW filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

DifferenceW(p, x, y)

DifferenceWHeight(s, g)

DifferenceWHeight(s, x, y)

Gravity(drawing, column, neighbors, g)
- Returns the value of the surface interpolated using gravity interpolation method at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. The surface is built from the specified drawing using the specified column as the height. Setting the number of neighbors to -1 will use the default number of neighbors. Surface Tools only.

Gravity(drawing, column, neighbors, x, y)

HasPixel(p, g)
- Returns True if s has a visible pixel at the specified location and False otherwise. The location is either the centroid of a geom or a pair of XY coordinates.

HasPixel(p, x, y)

Height(s, g)
- Returns average height of pixels covered by a geom or height of a pixel at an XY location in the given surface.

Height(s, x, y)

HeightAvg(s, g)
- Returns average height of pixels covered by a geom or average height of pixels in a window of specified size (1 for 3x3, 2 for 5x5, etc) centered at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. Window computations are available in Surface Tools only.

HeightAvg(s, g, w)

HeightAvg(s, x, y, w)

HeightCurvMean(s, g)
- Returns the mean curvature of s at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. Passing the w parameter computes curvature over a window of specified size (1 for 3x3, 2 for 5x5, etc). Surface Tools only.

HeightCurvMean(s, x, y)

HeightCurvMean(s, x, y, w)

HeightCurvPlan(s, g)
- Returns the plan curvature of s at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. Passing the w parameter computes curvature over a window of specified size (1 for 3x3, 2 for 5x5, etc). Surface Tools only.

HeightCurvPlan(s, x, y)

HeightCurvPlan(s, x, y, w)

HeightCurvProfile(s, g)
- Returns the profile curvature of s at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. Passing the w parameter computes curvature over a window of specified size (1 for 3x3, 2 for 5x5, etc). Surface Tools only.

HeightCurvProfile(s, x, y)

HeightCurvProfile(s, x, y, w)

HeightDiversity(s, g)
- Returns the number of different height values in pixels covered by a geom or the number of different height values in pixels in a window of specified size (1 for 3x3, 2 for 5x5, etc) centered at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. Window computations are available in Surface Tools only.

HeightDiversity(s, g, w)

HeightDiversity(s, x, y, w)

HeightDiversityIndex(s, g)
- Returns the diversity index of height values in pixels covered by a geom or the diversity index of height values in pixels in a window of specified size (1 for 3x3, 2 for 5x5, etc) centered at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. The diversity index is a value from 0 to 1. The greater the value of the diversity index, the less similar the height values. Window computations are available in Surface Tools only.

HeightDiversityIndex(s, g, w)

HeightDiversityIndex(s, x, y, w)

HeightMaj(s, g)
- Returns the most frequently occurring height of pixels covered by a geom or the most frequently occurring height
HeightMaj(s, g, w)  \-
| of pixels in a window of specified size (1 for 3x3, 2 for 5x5, etc) centered at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. Window computations are available in Surface Tools only.

HeightMaj(s, x, y, w)  \-
| of pixels in a window of specified size (1 for 3x3, 2 for 5x5, etc) centered at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. Window computations are available in Surface Tools only.

HeightMax(s)  \-
| Returns maximum height of pixels covered by a geom or maximum height of pixels in a window of specified size (1 for 3x3, 2 for 5x5, etc) centered at the specified location or maximum height of all pixels. The location is either the centroid of a geom or a pair of XY coordinates. Window computations are available in Surface Tools only.

HeightMax(s, g)  \-
| Returns maximum height of pixels covered by a geom or maximum height of pixels in a window of specified size (1 for 3x3, 2 for 5x5, etc) centered at the specified location or maximum height of all pixels. The location is either the centroid of a geom or a pair of XY coordinates. Window computations are available in Surface Tools only.

HeightMax(s, g, w)  \-
| Returns maximum height of pixels covered by a geom or maximum height of pixels in a window of specified size (1 for 3x3, 2 for 5x5, etc) centered at the specified location or maximum height of all pixels. The location is either the centroid of a geom or a pair of XY coordinates. Window computations are available in Surface Tools only.

HeightMax(s, x, y, w)  \-
| Returns maximum height of pixels covered by a geom or maximum height of pixels in a window of specified size (1 for 3x3, 2 for 5x5, etc) centered at the specified location or maximum height of all pixels. The location is either the centroid of a geom or a pair of XY coordinates. Window computations are available in Surface Tools only.

HeightMed(s, g)  \-
| Returns median (mean) height of pixels covered by a geom or median height of pixels in a window of specified size (1 for 3x3, 2 for 5x5, etc) centered at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. Window computations are available in Surface Tools only.

HeightMed(s, g, w)  \-
| Returns median (mean) height of pixels covered by a geom or median height of pixels in a window of specified size (1 for 3x3, 2 for 5x5, etc) centered at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. Window computations are available in Surface Tools only.

HeightMed(s, x, y, w)  \-
| Returns median (mean) height of pixels covered by a geom or median height of pixels in a window of specified size (1 for 3x3, 2 for 5x5, etc) centered at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. Window computations are available in Surface Tools only.

HeightMin(s)  \-
| Returns minimum height of pixels covered by a geom or minimum height of pixels in a window of specified size (1 for 3x3, 2 for 5x5, etc) centered at the specified location or minimum height of all pixels. The location is either the centroid of a geom or a pair of XY coordinates. Window computations are available in Surface Tools only.

HeightMin(s, g)  \-
| Returns minimum height of pixels covered by a geom or minimum height of pixels in a window of specified size (1 for 3x3, 2 for 5x5, etc) centered at the specified location or minimum height of all pixels. The location is either the centroid of a geom or a pair of XY coordinates. Window computations are available in Surface Tools only.

HeightMin(s, g, w)  \-
| Returns minimum height of pixels covered by a geom or minimum height of pixels in a window of specified size (1 for 3x3, 2 for 5x5, etc) centered at the specified location or minimum height of all pixels. The location is either the centroid of a geom or a pair of XY coordinates. Window computations are available in Surface Tools only.

HeightMin(s, x, y, w)  \-
| Returns minimum height of pixels covered by a geom or minimum height of pixels in a window of specified size (1 for 3x3, 2 for 5x5, etc) centered at the specified location or minimum height of all pixels. The location is either the centroid of a geom or a pair of XY coordinates. Window computations are available in Surface Tools only.

HeightSum(s)  \-
| Returns summed height of pixels covered by a geom or summed height of pixels in a window of specified size (1 for 3x3, 2 for 5x5, etc) centered at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. Used to compute cumulative figures such as population in a given region or to compute the volume of a surface (the HeightSum value multiplied by the size of a pixel). Window computations are available in Surface Tools only.

HeightSum(s, g)  \-
| Returns summed height of pixels covered by a geom or summed height of pixels in a window of specified size (1 for 3x3, 2 for 5x5, etc) centered at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. Used to compute cumulative figures such as population in a given region or to compute the volume of a surface (the HeightSum value multiplied by the size of a pixel). Window computations are available in Surface Tools only.

HeightSum(s, g, w)  \-
| Returns summed height of pixels covered by a geom or summed height of pixels in a window of specified size (1 for 3x3, 2 for 5x5, etc) centered at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. Used to compute cumulative figures such as population in a given region or to compute the volume of a surface (the HeightSum value multiplied by the size of a pixel). Window computations are available in Surface Tools only.

HeightSum(s, x, y, w)  \-
| Returns summed height of pixels covered by a geom or summed height of pixels in a window of specified size (1 for 3x3, 2 for 5x5, etc) centered at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. Used to compute cumulative figures such as population in a given region or to compute the volume of a surface (the HeightSum value multiplied by the size of a pixel). Window computations are available in Surface Tools only.

HighPass1(p, g)  \-
| Returns the value of the HighPass1 filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

HighPass1(p, x, y)  \-
| Returns the value of the HighPass1 filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

HighPass1Height(s, g)  \-
| Returns the value of the HighPass1 filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

HighPass1Height(s, x, y)  \-
| Returns the value of the HighPass1 filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

HighPass2(p, g)  \-
| Returns the value of the HighPass2 filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

HighPass2(p, x, y)  \-
| Returns the value of the HighPass2 filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

HighPass2Height(s, g)  \-
| Returns the value of the HighPass2 filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

HighPass2Height(s, x, y)  \-
| Returns the value of the HighPass2 filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

HighPass3(p, g)  \-
| Returns the value of the HighPass3 filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

HighPass3(p, x, y)  \-
| Returns the value of the HighPass3 filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

HighPass3Height(s, g)  \-
| Returns the value of the HighPass3 filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

HighPass3Height(s, x, y)  \-
| Returns the value of the HighPass3 filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

InterpolateHeight(s, g, radius)  \-
| Returns the value of s at the specified location if it is visible and the interpolated value if it is invisible. The location is either the centroid of a geom or a pair of XY coordinates. The interpolated value is computed as the average value of s in the smallest box centered at the current pixel that contains at least one visible pixel. If all pixels in s are invisible, the function returns Null. The last parameter specifies an interpolation radius over which interpolation occurs, a negative value specifies infinite radius. See the discussion for the Interpolate (Parameter) transform operator.

InterpolateHeight(s, x, y, radius)  \-
| Returns the value of s at the specified location if it is visible and the interpolated value if it is invisible. The location is either the centroid of a geom or a pair of XY coordinates. The interpolated value is computed as the average value of s in the smallest box centered at the current pixel that contains at least one visible pixel. If all pixels in s are invisible, the function returns Null. The last parameter specifies an interpolation radius over which interpolation occurs, a negative value specifies infinite radius. See the discussion for the Interpolate (Parameter) transform operator.

InterpolateRowHeight(s, g)  \-
| Returns the value of s at the specified location if it is visible and the interpolated value if it is invisible. The location is either the centroid of a geom or a pair of XY coordinates. The interpolated value is computed as the value of the straight line segment between the nearest visible pixels in the same row of s. If all pixels in the current row of s are
invisible, the function returns Null. Overall, this function works much faster than Interpolate but is also less accurate.

Kriging(drawing, column, neighbors, g)
Kriging(drawing, column, neighbors, x, y)
Kriging(drawing, column, neighbors, model, voronoi, g)
Kriging(drawing, column, neighbors, model, voronoi, x, y)

Returns the value of the interpolated surface at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. The surface is built from the specified drawing using the specified column as the height. Line objects participate as sets of their coordinates. Area objects are ignored. Setting the number of neighbors to -1 will use the default number of neighbors. The model argument is a case-insensitive string, e.g., "spherical" or "gaussian". Some models are only available in the Surface Tools extension. The voronoi argument is a boolean (if true, only Voronoi neighbors are used).

KrigingMedianPolish(drawing, column, neighbors, g)
KrigingMedianPolish(drawing, column, neighbors, x, y)
KrigingMedianPolish(drawing, column, neighbors, model, voronoi, g)
KrigingMedianPolish(drawing, column, neighbors, model, voronoi, x, y)

Returns the value of the surface interpolated using the median-polish kriging interpolation method at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. The surface is built from the specified drawing using the specified column as the height. Line objects participate as sets of their coordinates. Area objects are ignored. Setting the number of neighbors to -1 will use the default number of neighbors. The model argument is a case-insensitive string, e.g., "spherical" or "gaussian". The voronoi argument is a boolean (if true, only Voronoi neighbors are used). This function requires the Surface Tools extension.

Laplace1(p, g)
Laplace1(p, x, y)
Laplace1Height(s, g)
Laplace1Height(s, x, y)

Returns the value of the Laplace1 filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

Laplace2(p, g)
Laplace2(p, x, y)
Laplace2Height(s, g)
Laplace2Height(s, x, y)

Returns the value of the Laplace2 filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

LowPass1(p, g)
LowPass1(p, x, y)
LowPass1Height(s, g)
LowPass1Height(s, x, y)

Returns the value of the LowPass1 filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

LowPass2(p, g)
LowPass2(p, x, y)
LowPass2Height(s, g)
LowPass2Height(s, x, y)

Returns the value of the LowPass2 filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

LowPass3(p, g)
LowPass3(p, x, y)
LowPass3Height(s, g)
LowPass3Height(s, x, y)

Returns the value of the LowPass3 filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

MedianCross(p, g)
MedianCross(p, x, y)
MedianCrossHeight(s, g)
MedianCrossHeight(s, x, y)

Returns the value of the MedianCross filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

MedianSquare(p, g)

Returns the value of the MedianSquare filter at the specified location. The location is either the centroid of a
MedianSquare(p, x, y) Returns the value of the MedianSquare filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

MedianSquareHeight(s, g) Returns the area of a single pixel in p in the specified units, or in the units of p.

MedianSquareHeight(s, x, y) Returns the color of a pixel at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

MedianSquare5Height(s, g) Returns the height of a single pixel in p in the specified units, or in the units of p.

MedianSquare5Height(s, x, y) Returns the number of columns in p.

MedianSquare5Height(s, x, y) Returns the number of rows in p.

MedianSquare5Height(s, x, y) Returns the value of the MedianSquare5 filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

PixelArea(p[, unit]) Returns the value of the Sharpen filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

Pixel(p, g) Returns the value of the Sharpen filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

Pixel(p, x, y) Returns the value of the SharpenMore filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

PixelHeight(p[, unit]) Returns the slope of s at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. Passing the w parameter computes slope over a window of specified size (1 for 3x3, 2 for 5x5, etc).

PixelHeight(p, x, y) Returns the slope of s at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

PixelHeight(s, x, y) Returns the slope of s at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

PixelWidth(p[, unit]) Returns the slope of s at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

Sharpen(p, g) Returns the value of the Sharpen filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

Sharpen(p, x, y) Returns the value of the Sharpen filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

SharpenHeight(s, g) Returns the value of the SharpenMore filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

SharpenHeight(s, x, y) Returns the value of the SharpenMore filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

SharpenMore(p, g) Returns the value of the SharpenMore filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

SharpenMore(p, x, y) Returns the value of the SharpenMore filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

SharpenMoreHeight(s, g) Returns the value of the SharpenMore filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

SharpenMoreHeight(s, x, y) Returns the value of the SharpenMore filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates.

SlopeHeight(s, g) (was: Slope) Returns the value of the Tile filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. The last parameter is the tile size.

SlopeHeight(s, x, y) Returns the value of the Tile filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. The last parameter is the tile size.

SlopeHeight(s, x, y) Returns the value of the Tile filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. The last parameter is the tile size.

SlopeHeight(s, x, y) Returns the value of the Tile filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. The last parameter is the tile size.

Surface Tools only.

Tile(p, g, n) Returns the value of the Tile filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. The last parameter is the tile size.

Tile(p, x, y, n) Returns the value of the Tile filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. The last parameter is the tile size.

TileHeight(s, g, n) Returns the value of the TileMedian filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. The last parameter is the tile size.

TileHeight(s, x, y, n) Returns the value of the TileMedian filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. The last parameter is the tile size.

TileMedian(p, g, n) Returns the value of the TileMedian filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. The last parameter is the tile size.

TileMedian(p, x, y, n) Returns the value of the TileMedian filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. The last parameter is the tile size.

TileMedianHeight(s, g, n) Returns the value of the TileMedian filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. The last parameter is the tile size.

TileMedianHeight(s, x, y, n) Returns the value of the TileMedian filter at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. The last parameter is the tile size.

Triangulation(drawing, column, corners, g) Returns the value of the surface interpolated using the triangulation interpolation method at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. The surface is built from the specified drawing using the specified column as the height. Line objects participate as sets of their coordinates. Area objects are ignored. The corners argument specifies the height to use for corners, and can be set to NULL.

Triangulation(drawing, column, corners, x, y) Returns the value of the surface interpolated using the contour triangulation interpolation method at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. The surface is built from the specified drawing using the specified column as the height. Line objects participate as sets of their coordinates. Area objects are ignored. The corners argument specifies the height to use for corners, and can be set to NULL.

TriangulationContours(drawing, column,
The `TriangulationContours` function builds a surface from a specified drawing using a specified column as the height. Line objects participate as sets of their segments, with intersections between segments being resolved automatically. Area objects are ignored. The `corners` argument specifies the height to use for corners, and can be set to NULL.

The `Volume` function returns the volume covered by a geom or the volume of pixels in a window of specified size (1 for 3x3, 2 for 5x5, etc) centered at the specified location. The location is either the centroid of a geom or a pair of XY coordinates. The function assumes surface heights are in meters, and returns the volume in cubic meters. To compute volume, the system takes all pixels, computes the volume of each pixel multiplying its height (which can be negative) by its area, and sums the resulting volumes. Hence, the volume can be less than zero. Window computations are available in Surface Tools only.

### Color Manipulation Functions

Colors within images may be manipulated using the following functions. In the following functions, `c` is a color.

<table>
<thead>
<tr>
<th>Function</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARGB(a, r, g, b)</td>
<td>Combines given values for alpha, red, green and blue channels into a color.</td>
</tr>
<tr>
<td>BGR(b, g, r)</td>
<td>Combines given values for blue, green and red channels into a color.</td>
</tr>
<tr>
<td>BGRA(b, g, r, a)</td>
<td>Combines the given values for blue, green, red and alpha channels into a color.</td>
</tr>
<tr>
<td>Channel(c, n)</td>
<td>Extracts the value of the given channel of the color where n specifies the channel: 0 = blue, 1 = green, 2 = red, 3 = alpha.</td>
</tr>
<tr>
<td>HLS(h, l, s)</td>
<td>Combines given values for hue, lightness and saturation into a color.</td>
</tr>
<tr>
<td>Hue(c)</td>
<td>Extracts the hue of a color.</td>
</tr>
<tr>
<td>Intensity(c)</td>
<td>Extracts the brightness of a color (also known as &quot;luma&quot;). The name of the function has been kept for compatibility with previous versions of Manifold.</td>
</tr>
<tr>
<td>Lightness(c)</td>
<td>Extracts the lightness of a color.</td>
</tr>
<tr>
<td>RGB(r, g, b)</td>
<td>Combines given values for red, green and blue channels into a color.</td>
</tr>
<tr>
<td>Saturation(c)</td>
<td>Extracts the saturation of a color.</td>
</tr>
</tbody>
</table>

**Lightness** in the above is the same as `L` in classic HSL color space as used in traditional graphics arts. It is computed by the following formula:

$$l = \frac{\max(r, g, b) + \min(r, g, b)}{2}$$

See the Expressions topic for additional SQL expressions.

### Example: Transferring Aspect to Points
Suppose we have a drawing of points that are located in the same region of interest as a surface and we would like to compute the aspect of the surface at each point and to save that value as a data attribute for each point. This is easy to do using SQL as follows:

1. Open the drawing's table and add a new floating-point column named **Aspect**.
2. Create a new query.
3. Open the query and enter the following text for the query (substitute the name of the drawing for "Drawing" and the name of the surface for "Surface"):

   ```sql
   UPDATE [Drawing] SET [Aspect] = AspectHeight([Surface], Centroid([Geom (I)]));
   ```

4. Run the query. This will set the values in the **Aspect** column for each point to the aspect of the surface at that point's location.

Spatial Extensions

[Geocoding Extensions](#)
Comparison with Jet SQL

Jet is the Microsoft database engine used to build Microsoft's Access DBMS. Because it is available to Microsoft software developers as a free redistributable many third party applications also use Jet as the database application powering the application. Since Jet includes Microsoft's implementation of SQL, Jet SQL has become a very widely distributed implementation of SQL.

Enhanced Features of Manifold SQL

Manifold SQL provides the following enhanced features compared to Jet SQL:

- More powerful joins (can include multiple columns of any type, and use any Boolean expression).
- **SKIP** quantifier.
- No restrictions on types of nested joins (can nest INNER JOIN inside, for example, a LEFT JOIN and vice versa), FULL JOIN and CROSS JOIN operators.
- No restrictions on the number of logical expressions used in the HAVING and WHERE clauses.
- The ability to use records and lists of values in comparisons, BETWEEN AND, IN, and other operators.
- **CASE**, **COALESCE**, **NULLIF** and other ANSI operators.
- **LIKE** operator and true regular expressions in queries.
- **UNIQUE** operator.
- A pivot expression used in a TRANSFORM statement is not required to return a string.
- **SPLIT BY** and **LEAVING** clauses.
- **CAST** and other ANSI functions for use in expressions.
- Spatial extensions
- Geocoding extensions
- Raster extensions

Jet SQL Features Not Supported in Manifold SQL

Manifold SQL does not support the following features of Jet SQL:

- Security statements, such as GRANT and REVOKE.
- Transaction statements, such as COMMIT and ROLLBACK.
- Procedure statements.
- Constraints and indices (both are widely used implicitly in Manifold).
- NULL values in tables. NULL values in queries are fully supported.

Comparison with ANSI SQL

Manifold SQL is generally ANSI 92 compliant. However, certain ANSI SQL features are not implemented in Manifold SQL. Conversely, Manifold SQL includes reserved words and features not supported in ANSI SQL. These differences are normally exactly the same as those encountered when comparing Microsoft Jet SQL with ANSI SQL.

Manifold SQL and ANSI SQL each have different reserved words and data types. For more information, see the SQL Reserved Words / Index and Data types topics.

Enhanced Features of Manifold SQL

Manifold SQL provides the following enhanced features compared to ANSI SQL:

- Ability to change the type or name of a column with the ALTER TABLE statement.
- TOP and SKIP quantifiers.
- Ability to use the GROUP BY and ORDER BY clauses with expressions.
- Ability to use the ORDER BY clause in subqueries.
- VBScript-like functions for use in expressions.
- LIKEX operator and true regular expressions.
- TRANSFORM statement
- Additional aggregate functions, such as StDev and VarP
- Aggregate functions using DISTINCT with expressions (e.g., SUM(DISTINCT [A]+[B])).
- SPLIT BY and LEAVING clauses.
- PARAMETERS declaration for defining parameter queries.
- Spatial extensions
- Geocoding extensions
- Raster extensions

ANSI SQL Features Not Supported in Manifold SQL

Manifold SQL does not support the following ANSI SQL features:

- Security statements, such as GRANT and LOCK.
- Transaction statements, such as COMMIT and ROLLBACK.
- Constraints and indices (both are widely used implicitly in Manifold).
- NULL values in tables. NULL values in queries are fully supported.

Expressions

SQL queries can contain expressions. Expressions can contain literals and references to columns used by a query. There are several types of expressions with the most frequently used types being generic expressions, numeric expressions, string expressions, date expressions, and Boolean expressions.

Generic Expressions

Generic expressions are expressions that can return values of any type. Generic expressions can include the following functions:

<table>
<thead>
<tr>
<th>Function</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Coalesce(value, value[, value ...])</td>
<td>Returns the first value not equal to NULL.</td>
</tr>
<tr>
<td>If(condition, value, value)</td>
<td>Evaluates the condition and returns the first value if it is True, and the second value otherwise.</td>
</tr>
<tr>
<td>Max(v1, v2[, v3 ...])</td>
<td>Computes the maximum value in the list of values. Accepts any number of values of any type. NULL values are ignored. If all values are NULL, returns NULL.</td>
</tr>
<tr>
<td>Min(v1, v2[, v3 ...])</td>
<td>Computes the minimum value in the list of values. Accepts any number of values of any type. NULL values are ignored. If all values are NULL, returns NULL.</td>
</tr>
<tr>
<td>NullIf(value, value)</td>
<td>Returns NULL if the first value is equal to the second value, and the first value otherwise.</td>
</tr>
<tr>
<td>TypeName(value)</td>
<td>Returns the name of a value type.</td>
</tr>
<tr>
<td>VarType(value)</td>
<td>Returns an integer value representing a value type.</td>
</tr>
</tbody>
</table>

Numeric Expressions and Functions

Numeric expressions are expressions that return numeric values. Numeric expressions can include numeric literals. Numeric expressions can include the following arithmetic operators (in order of increasing priority):

+ Addition
- Subtraction
/ Division
* Multiplication
Div Integer division, equivalent to VBScript \\ (*
Mod Modulo. Performs a division, retaining only the remainder. [Note: this is in line with VB.NET but different from VBScript, which first converts floating point numbers to integers via rounding and then performs the division.]
^ Exponentiation

Numeric expressions can be used with the following functions:

<table>
<thead>
<tr>
<th>Function</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abs(number)</td>
<td>Returns the absolute value of a number.</td>
</tr>
<tr>
<td>Acos(number)</td>
<td>Returns the arc cosine of a number.</td>
</tr>
</tbody>
</table>
Asin(number) Returns the arc sine of a number.
Atn(number) Returns the arc tangent of a number.
Atn2(y, x) Returns the arc tangent of y/x.
Ceil(x) Returns the smallest integer that is greater than or equal to x.
Cos(number) Returns the cosine of a number.
Deg2Rad(x) Converts x from degrees to radians.
Exp(number) Returns the exponent of a number.
Fix(number) Converts a fractional number to an integer number rounding towards zero.
Floor(x) Returns the largest integer that is less than or equal to x.
Int(number) Converts a fractional number to an integer number rounding down.
Log(number) Returns the natural logarithm of a number.
Log2(x) Returns the binary logarithm of x.
Log10(x) Returns the decimal logarithm of x.
Pow(x, y) Returns the value of x raised to the power of y.
Rad2Deg(x) Converts x from radians to degrees.
Rgb(red, green, blue) Composes red, green, and blue components of a color into an integer number.
Rnd Returns a random number between 0 and 1. Used without parentheses.
Round(number[, decimals]) Rounds a fractional number to a given number of decimal digits and returns the result. If the number of decimal digits is omitted, it is assumed to be 0.
Sgn(number) Returns the sign of a number.
Sin(number) Returns the sine of a number.
Sqr(number) Returns the square root of a number.
Tan(number) Returns the tangent of a number.

String Expressions

String expressions are expressions that return string values. String expressions can include string literals. String expressions can be concatenated with ||, +, or & operators. String expressions can be used with the following functions:

<table>
<thead>
<tr>
<th>Function</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit_Length(string)</td>
<td>Returns the length of a string in bits (an ANSI character is 8 bit wide and a Unicode character is 16 bit wide). Also supports binary values.</td>
</tr>
<tr>
<td>Char_Length(string)</td>
<td>Returns the length of a string in characters.</td>
</tr>
<tr>
<td>Character_Length(string)</td>
<td>Same as Char_Length(string).</td>
</tr>
<tr>
<td>Chr(number)</td>
<td>Returns a character with the given numeric value.</td>
</tr>
</tbody>
</table>
**FormatCurrency(number[, decimals[, leading[, parens[, groups]]]])**
Prints a currency value into a string using the given number of decimal digits (system-defined by default). The third parameter specifies whether a leading zero is included (-1) or excluded (0). The fourth parameter specifies whether negative values are printed in parentheses (-1) or not (0). The fifth parameter specifies whether the numbers are grouped (-1) or not (0). The third, fourth, and fifth parameters can be set to be taken from the regional settings of the current user (-2, the default).

**FormatDateTime(date[, format])**
Prints a date into a string using either the default format (0), long date format (1), short date format (2), long time format (3), or short time format (4, uses 24 hours).

**FormatNumber(number[, decimals[, leading[, parens[, groups]]]])**
Prints a number into a string using the given number of decimal digits (system-defined by default). The third parameter specifies whether a leading zero is included (-1) or excluded (0). The fourth parameter specifies whether negative values are printed in parentheses (-1) or not (0). The fifth parameter specifies whether the numbers are grouped (-1) or not (0). The third, fourth, and fifth parameters can be set to be taken from the regional settings of the current user (-2, the default).

**FormatPercent(number[, decimals[, leading[, parens[, groups]]]])**
Prints a percentage into a string using the given number of decimal digits (system-defined by default). The third parameter specifies whether a leading zero is included (-1) or excluded (0). The fourth parameter specifies whether negative values are printed in parentheses (-1) or not (0). The fifth parameter specifies whether the numbers are grouped (-1) or not (0). The third, fourth, and fifth parameters can be set to be taken from the regional settings of the current user (-2, the default).

**Hex(number)**
Prints an integer number into a string using hexadecimal notation.

**InStr(string, string[, start[, case]])**
Returns the position of the first occurrence of the second string in the first string, or 0 if there are no occurrences. The third parameter specifies the starting position of a search (1 by default). The fourth parameter specifies whether the search is case-sensitive (0, the default), or case-insensitive (1).

**InStrRev(string, string[, start[, case]])**
Returns the position of the last occurrence of the second string within the first string, or 0 if there are no occurrences. The third parameter specifies the starting position of a search (1 by default). The fourth parameter specifies whether the search is case-sensitive (0, the default), or case-insensitive (1).

**Left(string, length)**
Returns the given number of starting characters in a string.

**Len(string)**
Same as Char_Length(string).

**LCase(string)**
Converts all string characters to lower case and returns the result.

**Lower(string)**
Same as LCase(string).

**LTrim(string)**
Trims leading white space characters from a string and returns the result.

**Mid(string, start[, length])**
Returns the portion of a string starting with a given character (one-based). If the length parameter is omitted, the function returns the rest of the string.

**Oct(number)**
Prints an integer number into a string using octal notation.

**Octet_Length(string)**
Returns the length of a string in bytes (an ANSI character is 1 byte wide and a Unicode character is 2 byte wide). Also supports binary values.

**RegExp(string, pattern, substitute)**
Transforms a string with regular expressions and returns the result.

**Replace(string, what, with[, start[, count[, case]]])**
Replaces all occurrences of one substring in a string with another substring, and returns the result. The fourth parameter specifies the starting position of a search (1 by default). The
fifth parameter specifies the maximum number of substitutions to perform and can be set to -1 (the default) to perform all possible substitutions. The sixth parameter specifies whether the search is case-sensitive (0, the default), or case-insensitive (1).

**Right(string, length)** Returns the given number of trailing characters in a string.

**RTrim(string)** Trims trailing white space characters from a string and returns the result.

**SoundsLike(string, string)** Returns True if strings sound like each other, and False otherwise. Uses Soundex algorithm for English language.

**Space(number)** Returns a string with the given number of spaces.

**StrComp(string, string[, case])** Compares two strings and returns -1 if the first string is less than the second string, 1 if the first string is greater than the second string, and 0 if the strings are equal. The third parameter specifies whether the comparison is case-sensitive (0, the default), or case-insensitive (1).

**String(number, character)** Returns a string with the given number of given characters. The second parameter can be either a string (that gets reduced to the first character), or a number (that gets converted to a string with a Chr function).

**StrReverse(string)** Reverses a string and returns the result.

**Token(string[, index[, delimiters]]** Returns a token with the given index (one-based). The third parameter is a string that contains token delimiters. If the third parameter is omitted, tokens are separated with white space characters.

**UCase(string)** Converts all string characters to upper case and returns the result.

**Upper(string)** Same as UCase(string).

**Date Expressions**

Date expressions are expressions that return date values. Date expressions can include date literals. Date expressions can be used with the following functions:

<table>
<thead>
<tr>
<th>Function</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Current_Date</strong></td>
<td>Same as Date. Used without parentheses.</td>
</tr>
<tr>
<td><strong>Current_Time</strong></td>
<td>Same as Time. Used without parentheses.</td>
</tr>
<tr>
<td><strong>Current_TimeStamp</strong></td>
<td>Same as Time. Used without parentheses.</td>
</tr>
<tr>
<td><strong>Date</strong></td>
<td>Returns the current date. Used without parentheses.</td>
</tr>
<tr>
<td><strong>DateAdd(interval, number, date)</strong></td>
<td>Increases or decreases a date by the given value in the given time interval, and returns the result. The first parameter is a string that specifies which interval to increase (&quot;yyyy&quot; for year, &quot;q&quot; for quarter, &quot;m&quot; for month, &quot;y&quot; for day of year, &quot;d&quot; for day of month, &quot;w&quot; for weekday, &quot;ww&quot; for week of year, &quot;h&quot; for hour, &quot;n&quot; for minute, and &quot;s&quot; for second).</td>
</tr>
<tr>
<td><strong>DateDiff(interval, date, date[, start[, week]]</strong></td>
<td>Returns the number of time intervals between two dates. The first parameter is a string that specifies the time interval. The fourth parameter is the numeric index of a day that starts the week (0 for the default start, 1 for Sunday, 2 for Tuesday, and so on). The fifth parameter is a number that specifies the method used to determine the first week in a year (0 for the default method, 1 to use the week that contains the 1st of January, 2 to use the first week that contains at least 4 days in the new year, 3 to use the first week that is entirely in the new year).</td>
</tr>
</tbody>
</table>
DatePart(interval, date[, start[, week]]) Returns the value of a specified time interval in a date. The first parameter is a string that specifies the time interval. The third parameter is the numeric index of a day that starts the week. The fourth parameter is a number that specifies the method used to determine the first week in a year.

DateSerial(year, month, day) Composes a date without a time.

DateValue(value) Converts a value to a date without a time ignoring hour, minute, and second information.

Day(date) Returns the day of month of a date (1 to 31).

Hour(date) Returns the hour of a date (0 to 23).

Minute(date) Returns the minute of a date (0 to 59).

Month(date) Returns the month of a date (1 to 12).

MonthName(month[, abbreviate]) Returns the name of a month (1 to 12). The second parameter switches between abbreviated names (True) and full names (False, the default).

Now Same as Time. Used without parentheses.

Second(date) Returns the second of a date (0 to 59).

Time Returns the current date and time. Used without parentheses.

Timer Returns the number of seconds since 12:00 AM. Used without parentheses.

TimeSerial(hour, minute, second) Composes the time portion of a date.

TimeValue(value) Converts a value to the time portion of a date ignoring year, month, and day information.

Weekday(date[, start]) Returns the weekday of a date (1 to 7). The second parameter is the numeric index of a day that starts the week (0 for the default start, 1 for Sunday, 2 for Tuesday, and so on).

WeekdayName(day[, abbreviation[, start]]) Returns the name of a weekday (1 to 7). The second parameter switches between abbreviated names (True) and full names (False, the default). The third parameter is the numeric index of a day that starts the week.

Year(date) Returns the year of a date.

Boolean Expressions

Boolean expressions are expressions that return Boolean values. Boolean expressions can include Boolean literals, such as True and False, or Yes and No. Boolean expressions can include the following comparison operators:

> Greater than
< Less than
<> Not equal to
>= Greater than or equal to
<= Less than or equal to
= Equal to
When applied to strings, the above operators work from the leftmost to the rightmost character, comparing characters in alphabetical order (typically, A is less than B, B is less than C, digits are less than letters, upper case letters are less than lower case letters, etc.)

Boolean expressions can also include the following Boolean operators:

- **And**: Logical AND (True if both operands are True)
- **Or**: Logical OR (True if either operand is True)
- **Not**: Logical NOT (True if the operand is False)
- **Eqv**: Logical equivalence (True if both operands are either True or False)
- **Imp**: Logical implication (True unless the first operand is True and the second operand is False)
- **Xor**: Logical XOR (True if one of the operands is True, and another is False)

**Conversion Functions**

The expressions can also include the following functions that convert values from one type to another:

<table>
<thead>
<tr>
<th>Function</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>BinaryToHex(value)</td>
<td>Converts a typed (for example, Geom) or untyped binary value to a text value, printing each byte using hexadecimal notation.</td>
</tr>
<tr>
<td>CBool(value)</td>
<td>Converts a value to a Boolean.</td>
</tr>
<tr>
<td>CByte(value)</td>
<td>Converts a value to a 8 bit unsigned integer number (byte).</td>
</tr>
<tr>
<td>CCoordSys(value)</td>
<td>Converts a value to a coordinate system.</td>
</tr>
<tr>
<td>CCur(value)</td>
<td>Converts a value to a currency.</td>
</tr>
<tr>
<td>CDate(value)</td>
<td>Converts a value to a date.</td>
</tr>
<tr>
<td>CDbl(value)</td>
<td>Converts a value to a double precision floating-point number.</td>
</tr>
<tr>
<td>CGeom (value)</td>
<td>Converts a value to a geometric object of type Geometry.</td>
</tr>
<tr>
<td>CGeomSDE(value)</td>
<td>Converts given data to geometric object of type Geometry (SDE).</td>
</tr>
<tr>
<td>CGeomSHP(value)</td>
<td>Converts given data to geometric object of type Geometry (SHP).</td>
</tr>
<tr>
<td>CGeomWKB(value)</td>
<td>Converts given data to geometric object of type Geometry (WKB).</td>
</tr>
<tr>
<td>CInt(value)</td>
<td>Converts a value to a 32 bit integer number.</td>
</tr>
<tr>
<td>CLng(value)</td>
<td>Converts a value to a 32 bit integer number (same as CInt).</td>
</tr>
<tr>
<td>CSng(value)</td>
<td>Converts a value to a single precision floating-point number.</td>
</tr>
<tr>
<td>CStr(value)</td>
<td>Converts a value to a string.</td>
</tr>
<tr>
<td>HexToBinary(value)</td>
<td>Converts a text value in the hexadecimal notation format used by the BinaryToHex function to an untyped binary value.</td>
</tr>
</tbody>
</table>

The **BinaryToHex** and **HexToBinary** functions are used to convert binary data to text format and vice versa. They are especially useful for storing binary data within data sources such as DBF files that do not support binary data columns.
Lookup Values and CStr and CAST

Invoking CStr on a lookup value or using CAST to convert the value to a string returns the descriptive name of the lookup value.

Example

We have a table T with a lookup column Region with values East and West. We want to select all records with the value of Region being East. We can do this with the following query:

```
SELECT * FROM [T] WHERE CStr([Region]) = "East";
```

Example

We have a drawing D and we want to select all areas it contains. We can do this with the following query:

```
SELECT * FROM [D] WHERE CAST([Type (I)]) AS TEXT) = "Area";
```

Historical Note

The term "Boolean" takes its name from George Boole (1815 -1864), one of the great mathematicians of the nineteenth century and the inventor of mathematical logic and Boolean algebra, a systematic means of writing and manipulating logical concepts using mathematical symbols. Boolean algebra is the foundation of digital computer architecture.

Boole wrote fifty papers, two textbooks and two major volumes of work on mathematical logic and was a professor at Queen's College in Cork despite never having attended college or earning a degree. He was entirely self-taught. The son of a poor London shoemaker, Boole was encouraged by his father to pursue an early interest in learning. By age 12 he had mastered Latin and Greek and later turned his attention to mathematics. He died at 49 from an illness apparently incurred as a result of giving a lecture in soaking wet clothes after walking two miles through the rain. His untimely death interrupted a very productive career. One wonders what marvels the world lost for lack of an umbrella.

In English, George Boole's name is pronounced with a silent "e" to rhyme with "tool" or "cool".
Aggregate Functions

An aggregate function is a function that calculates the total value of a group of values. Aggregate functions are commonly used with the GROUP BY clause, and with the TRANSFORM statement.

The following table lists available aggregate functions:

<table>
<thead>
<tr>
<th>Function</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>AllBranches</td>
<td>Combines all branches of geometric objects into a single object. See the Spatial Extensions topic.</td>
</tr>
<tr>
<td>AllCoords</td>
<td>Combines all coordinates of geometric objects into a single object. See the Spatial Extensions topic.</td>
</tr>
<tr>
<td>Avg</td>
<td>Calculates the arithmetic mean of a set of numeric values.</td>
</tr>
<tr>
<td>Count</td>
<td>Calculates the number of values in a set of values of any type.</td>
</tr>
<tr>
<td>First</td>
<td>Retrieves the first value in a set of values of any type.</td>
</tr>
<tr>
<td>Last</td>
<td>Retrieves the last value in a set of values of any type.</td>
</tr>
<tr>
<td>Max</td>
<td>Calculates the maximum value in a set of numeric, string, or date values.</td>
</tr>
<tr>
<td>Min</td>
<td>Calculates the minimum value in a set of numeric, string, or date values.</td>
</tr>
<tr>
<td>StDev</td>
<td>Calculates the standard deviation of a set of numeric values. Requires at least two values.</td>
</tr>
<tr>
<td>StDevP</td>
<td>Calculates the unadjusted standard deviation of a set of numeric values.</td>
</tr>
<tr>
<td>Sum</td>
<td>Calculates the sum of a set of numeric values.</td>
</tr>
<tr>
<td>UnionAll</td>
<td>Unions all areas into a single area. See the Spatial Extensions topic.</td>
</tr>
<tr>
<td>Var</td>
<td>Calculates the variation in a set of numeric values. Requires at least two values.</td>
</tr>
<tr>
<td>VarP</td>
<td>Calculates the unadjusted variation in a set of numeric values.</td>
</tr>
</tbody>
</table>

All aggregate functions ignore NULL values. If the set of values is empty, the Count function returns 0, and all other aggregate functions return NULL.

Examples

This example uses the Avg aggregate function to calculate the average freight charges for orders with freight charges over $100.

```
SELECT Avg([Freight]) AS [Average Freight] FROM [Orders] WHERE [Freight] > 100;
```

This example uses the Sum, Avg, and StDev aggregate functions to calculate the total number of units, the average number of units, and the standard deviation of the number of units ordered for each product:

```
SELECT [Product Name], Sum([Quantity]) AS [Total Quantity], Avg([Quantity]) AS [Typical Quantity], StDevP([Quantity]) AS [Standard Deviation] FROM [Products] INNER JOIN [Order Details] ON [Order Details].[Product ID] = [Products].[Product ID] GROUP BY [Product Name];
```
This example uses the Max and Min aggregate functions to calculate the maximum and minimum order adjusted for discount, and the maximum discount made on each product:

```sql
SELECT [Product Name], Min([Order Details].[Unit Price] * (1-[Discount]) * [Quantity]) AS [Min Value], Max([Order Details].[Unit Price] * (1-[Discount]) * [Quantity]) AS [Max Value], Max([Discount]) AS [Max Discount] FROM [Products] INNER JOIN [Order Details] ON [Order Details].[Product ID] = [Products].[Product ID] GROUP BY [Product Name];
```

This example uses the Max and Min aggregate functions to select the first and the last order for each product in 1992:

```sql
SELECT [Product Name], Min([Order Date]) AS [First Order], Max([Order Date]) AS [Last Order] FROM ([Orders] INNER JOIN [Order Details] ON [Order Details].[Order ID] = [Orders].[Order ID]) INNER JOIN [Products] ON [Products].[Product ID] = [Order Details].[Product ID] WHERE Year([Order Date]) = 1992 GROUP BY [Product Name];
```

**Statements**

**ALTER TABLE Statement**

Modifies the design of an existing table.

**Syntax**

```sql
ALTER TABLE table {
    ADD [COLUMN] column type [(size)] [DEFAULT default] |
    ALTER [COLUMN] column type [(size)] [DEFAULT default] |
    ALTER [COLUMN] column SET DEFAULT default |
    DROP [COLUMN] column |
    RENAME [COLUMN] column TO columnNew
}
```

The ALTER TABLE statement has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>The name of the table to be altered.</td>
</tr>
<tr>
<td>column</td>
<td>The name of the column to be altered or added to or deleted from table.</td>
</tr>
<tr>
<td>columnNew</td>
<td>The new name of the altered column.</td>
</tr>
<tr>
<td>type</td>
<td>The data type of column.</td>
</tr>
<tr>
<td>size</td>
<td>The size of the altered column in characters or bytes for text or binary columns.</td>
</tr>
<tr>
<td>default</td>
<td>An expression defining the new default value of the altered column. Can contain literal values, and functions of these values.</td>
</tr>
</tbody>
</table>

**Remarks**

Using the ALTER TABLE statement, we can alter an existing table in several ways. We can:

- Use ADD COLUMN to add a new column to the table. Specify the name, data type, an optional size, and an optional default value of the column.
- Use ALTER COLUMN to alter type, size or default value of an existing column.
- Use DROP COLUMN to delete a column. Specify only the name of the column.
- Use RENAME COLUMN to rename an existing column.

We cannot add, delete or modify more than one column at a time.

The ALTER TABLE statement is an action query and cannot be used from within the Manifold ODBC driver.

**Examples**

Add a currency Salary column to the Employees table:

```
ALTER TABLE [Employees] ADD COLUMN [Salary] CURRENCY;
```

Remove the Salary column from the Employees table. (Oh no!...):

```
ALTER TABLE [Employees] DROP COLUMN [Salary];
```

Add a text Rank column with the default value of "High" to the Employees table:

```
ALTER TABLE [Employees] ADD COLUMN [Rank] TEXT DEFAULT "High";
```

Change the default value of the Rank column added above to "Medium":

```
ALTER TABLE [Employees] ALTER COLUMN [Rank] SET DEFAULT "Medium";
```

Change the type of the Rank column added above to fixed-length text with 10 characters:

```
ALTER TABLE [Employees] ALTER COLUMN [Rank] TEXT(10);
```
CREATE DRAWING Statement

Creates a new table.

Syntax

CREATE DRAWING drawing [(column type [(size)] [DEFAULT default] [, column type [(size)] ...])]

The CREATE DRAWING statement has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>drawing</td>
<td>The name of the drawing to be created.</td>
</tr>
<tr>
<td>column</td>
<td>The name of the column or columns to be created in the table bound to the new drawing, in addition to the ID column and intrinsic columns.</td>
</tr>
<tr>
<td>type</td>
<td>The data type of the column in the table bound to the new drawing.</td>
</tr>
<tr>
<td>size</td>
<td>The column size in characters or bytes for text or binary columns.</td>
</tr>
<tr>
<td>default</td>
<td>The expression defining the default value of column in the table bound to the new drawing. Can contain literal values, and functions of these values.</td>
</tr>
</tbody>
</table>

Remarks

Use the CREATE DRAWING statement to define a new drawing. The CREATE DRAWING statement is similar to the CREATE TABLE statement, except that it creates a drawing together with the ID column and the intrinsic columns, and does not require supplying extra columns. All text columns are created as Unicode text type columns.

The CREATE DRAWING statement is an action query and cannot be used from within the ODBC driver.

To define a new table not bound to a drawing, use the CREATE TABLE statement.

Examples

This example creates a new drawing called "This Drawing" with only the ID column and intrinsic columns:

```
CREATE DRAWING [This Drawing];
```

This example creates a new drawing called "This Drawing" with the ID column, intrinsic columns and an integer column:

```
CREATE DRAWING [This Drawing] ([Population] INTEGER);
```
CREATE TABLE Statement
Creates a new table.

Syntax

```
CREATE TABLE table (column type [(size)] [DEFAULT default]
[, column type [(size)] ...])
```

The CREATE TABLE statement has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>The name of the table to be created.</td>
</tr>
<tr>
<td>column</td>
<td>The name of the column or columns to be created in the new table. We must create at least one column.</td>
</tr>
<tr>
<td>type</td>
<td>The data type of the column in the new table.</td>
</tr>
<tr>
<td>size</td>
<td>The column size in characters or bytes for text or binary columns.</td>
</tr>
<tr>
<td>default</td>
<td>The expression defining the default value of column in the new table. Can contain literal values, and functions of these values.</td>
</tr>
</tbody>
</table>

Remarks

Use the CREATE TABLE statement to define a new table and its columns. All text columns are created as Unicode text type columns.

The CREATE TABLE statement is an action query and cannot be used from within the ODBC driver.

To define a new drawing, use the CREATE DRAWING statement.

Examples

This example creates a new table called "This Table" with two text columns.

```
CREATE TABLE [This Table] ([First Name] TEXT, [Last Name] TEXT);
```

This example creates a new table called "My Table" with two text columns and a date/time column.

```
CREATE TABLE [My Table] ([First Name] TEXT, [Last Name] TEXT, [Birth Date] DATETIME);
```

This example creates a new table with two text columns of specified length (20 and 40 characters respectively) and an integer column with a default value of -1.

```
CREATE TABLE [New Table] ([First Name] TEXT(20), [Last Name] TEXT(40), [SSN] INTEGER DEFAULT -1);
```

This example creates a new table called "Orders" with a text column, an integer column with a default value of 1, and a date/time column with a default value equal to the 20th of September 2003:

```
CREATE TABLE [Orders] ([Product] TEXT, [Quantity] INTEGER DEFAULT 1, [Date] DATETIME DEFAULT #20/09/2003#);
```
CREATE VIEW Statement
Creates a new query.

Syntax

CREATE VIEW query AS text

The CREATE VIEW statement has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>The name of the query to be created.</td>
</tr>
<tr>
<td>text</td>
<td>The text of the new query. Should not be an action query</td>
</tr>
</tbody>
</table>

Remarks

Use the CREATE VIEW statement to create a new query that returns records.

The CREATE VIEW statement is an action query and can not be used from within the ODBC driver.

The CREATE VIEW query statement allows creating a query referring to a table or column that does not yet exist. Obviously, this capability should be used with reasonable care and foresight.

Examples

This example creates a new query named "Large Cities" that selects cities whose population exceeds 1,000,000 from the "Cities" table:

```
CREATE VIEW [Large Cities] AS
SELECT * FROM [Cities] WHERE [Population] > 1000000;
```

This example creates a new query named "Large American Cities" that selects American cities from the "Large Cities" query created above:

```
CREATE VIEW [Large American Cities] AS
SELECT * FROM [Large Cities] WHERE [Region] = "North America";
```
DELETE Statement
Removes records from a specified table.

Syntax

```sql
DELETE FROM table [WHERE ...]
```

The DELETE statement has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>The name of the table from which records are deleted.</td>
</tr>
</tbody>
</table>

Remarks

The DELETE statement is especially useful when we want to delete many records. Unlike the UPDATE statement that can operate on queries, the DELETE statement can only delete records from tables.

To drop an entire table use the DROP TABLE statement. If we delete the table, however, the structure is lost. In contrast, when we use DELETE, only the data is deleted; the table structure and all of the table properties, such as column formatting and transfer rules, remain intact.

The DELETE statement deletes entire records, not just data in specific columns. If we want to delete values in a specific column, we use the UPDATE statement.

The DELETE statement is an action query and cannot be used from within the Manifold ODBC driver.

Important

After we remove records using a DELETE query, we can't undo the operation. If we want to know which records were deleted, first examine the results of a SELECT query that uses the same criteria, and then run the DELETE query.

Maintain backup copies of data at all times. If we delete the wrong records, we can retrieve them from our backup copies.

Example

Delete all records for employees whose title is Trainee:

```sql
DELETE FROM [Employees] WHERE [Title] = "Trainee";
```
DROP DRAWING Statement

Deletes an existing table.

Syntax

DROP DRAWING drawing

The DROP DRAWING statement has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>drawing</td>
<td>The name of the drawing to be deleted, or the name of the table bound to the drawing to be deleted, or the name of a child theme of the drawing to be deleted.</td>
</tr>
</tbody>
</table>

Remarks

We can use CREATE DRAWING to create both a drawing and a table bound to that drawing and ALTER TABLE to modify the table.

We cannot use DROP DRAWING to delete a query. To delete a query, use DROP VIEW.

The DROP DRAWING statement is an action query and cannot be used from within the Manifold ODBC driver.

Example

Delete a drawing named "Cities":

DROP DRAWING [Cities];
**DROP TABLE Statement**
Deletes an existing table.

**Syntax**

```
DROP TABLE table
```

The DROP TABLE statement has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>The name of the table to be deleted.</td>
</tr>
</tbody>
</table>

**Remarks**

We can use CREATE TABLE to create a table and ALTER TABLE to modify a table.

We cannot use DROP TABLE to delete a query. To delete a query, use DROP VIEW.

The DROP TABLE statement is an action query and cannot be used from within the Manifold ODBC driver.

Attempting to delete a table bound to a drawing using DROP TABLE will fail with a descriptive error message.

**Example**

Delete a table named "Employees":

```
DROP TABLE [Employees];
```
DROP VIEW Statement
Deletes an existing query.

Syntax

DROP VIEW query

The DROP VIEW statement has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>The name of the query to be deleted.</td>
</tr>
</tbody>
</table>

Remarks

We can use CREATE VIEW to create a query.

We cannot use DROP VIEW to delete a table. To delete a table, use DROP TABLE.

The DROP VIEW statement is an action query and cannot be used from within the Manifold ODBC driver.

Example

Delete a query named "Youngest Employee":

```sql
DROP VIEW [Youngest Employee];
```
INSERT INTO Statement

Adds a record or multiple records to a table.

Syntax

```
INSERT INTO table {DEFAULT VALUES | [(column [, column ...])]} query
```

The INSERT INTO statement has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>The name of the table to which records are to be appended.</td>
</tr>
<tr>
<td>column</td>
<td>The name of a column in the target table.</td>
</tr>
<tr>
<td>query</td>
<td>A SELECT query.</td>
</tr>
</tbody>
</table>

Remarks

We can use the INSERT INTO statement to insert either a single record with default values, or to insert one or more records with arbitrary values. Records are added to the end of the table.

The list of columns specifies the columns to insert to. Columns in the target table that are not mentioned in the list of columns are supplied with default values. Omitting the list of columns is equivalent to specifying all columns in the order they appear in the target table.

Using the INSERT INTO statement with a SELECT query that returns a table inserts the records returned by the query. If the number of columns in the returned table does not match the number of columns in the list of target columns, the statement will fail. The columns in the returned table are matched to those in the list of target columns using their order, that is, the first column in the returned table is matched to the first target column, the second column in the returned table is matched to the second target column and so on. The types and sizes of columns in the returned table must be compatible with those of the target columns. The names of columns are ignored.

Using the INSERT INTO statement with a VALUES variation of a SELECT query inserts the literal values specified in the query. If the number of supplied values is not an even multiple of the number of columns in a column list, or not an even multiple of the number of columns in the target table if the column list is omitted, the statement will fail.

To create a new table, use the SELECT INTO statement.

To find out which records will be appended before we run the INSERT INTO query, we first execute and view the results of a SELECT query that uses the same selection criteria.

The INSERT INTO statement is an action query and cannot be used from within the Manifold ODBC driver.

Examples

Create a new blank record in the "Customers" table:

```
INSERT INTO [Customers] DEFAULT VALUES;
```

Select all records in a hypothetical "New Customers" table and add them to the "Customers" table. When individual columns are not designated, the number of columns in the table returned by the SELECT must match that in the target table:

```
INSERT INTO [Customers] SELECT * FROM [New Customers];
```
This example is identical to the above but uses simplified syntax for the SELECT portion:

```
INSERT INTO [Customers] TABLE [New Customers];
```

Create a new record in the "Employees" table. The first name is Harry, the last name is Washington, and the job title is Trainee:

```
INSERT INTO [Employees] ([First Name], [Last Name], [Title]) VALUES ("Harry", "Washington", "Trainee");
```

Add a point at the 0,0 coordinate location to an existing drawing called "Drawing" using the \texttt{Geom (I)} intrinsic field:

```
INSERT INTO [Drawing] ([Geom (I)])
VALUES (CGeom(CGeomWKB("point (0 0)")));
**SELECT Statement**

Selects data from existing tables or queries.

**Syntax**

\[
\text{atom \{UNION | EXCEPT | INTERSECT\} [ALL] atom ...} \] [ORDER BY ...]
\]

where \text{atom} is:

\[
\text{SELECT [ALL | DISTINCT | DISTINCTROW] [SKIP n [PERCENT]]} \]
\[
\text{[TOP n [PERCENT]]} \] \text{column [, column ...]} \]
\[
\text{FROM table [, table ...]} \]
\[
\text{[WHERE ...]} \] [SPLIT BY ...] [LEAVING ...] [GROUP BY ...] \]
\[
\text{[HAVING ...]} \]
\]
or:

\[
\text{TABLE table} \]
\]
or:

\[
\text{VALUES \{value | NULL\[, \{value | NULL\} ...\]} [, \{(value | NULL\[, \{value | NULL\} ...\]} ...\]} [NAMES (name[, name ...])] \]
\]

The SELECT statement has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column</td>
<td>The name of a column or an asterisk, possibly qualified with the name of a table as in [Table].[Column], or [Table]*, or an expression. Can include an alias. A non-qualified asterisk selects all columns, and must be the only item in the column list.</td>
</tr>
<tr>
<td>n</td>
<td>The number of records in SKIP or TOP or percent in SKIP PERCENT or TOP PERCENT.</td>
</tr>
<tr>
<td>name</td>
<td>The name to use for a column.</td>
</tr>
<tr>
<td>table</td>
<td>The name of a table containing the data for a TABLE variant. The name of a table containing data (with a possible alias, and column filter), or another query, or several tables or queries joined together with one of the join operators, for a SELECT variant.</td>
</tr>
<tr>
<td>value</td>
<td>A literal value, or an expression, or a query that returns a single value.</td>
</tr>
</tbody>
</table>

**Remarks**

SELECT statements don't change data. The minimum syntax for a SELECT statement is:

\[
\text{SELECT columns FROM table;}
\]

We can use an asterisk (*) to select all columns in a table. The following example selects all columns in the Employees table:

\[
\text{SELECT * FROM [Employees];}
\]
We may restrict the table to return only the columns we want with a table filter. The following example restricts the output of the above query to just the "First Name," and "Last Name" columns:

```sql
SELECT [First Name], [Last Name] FROM [Employees];
```

Alternatively, we may specify the columns we want in the FROM clause. The following example is identical to the above query but uses the FROM clause:

```sql
SELECT * FROM [Employees] ([First Name], [Last Name]);
```

If a column name is included in more than one table in the FROM clause, precede it with the table name and a dot (.). In the following example, the "Category ID" column is in both the "Products" table and the "Categories" table. The statement selects product names from the "Products" table and category names from the "Categories" table:

```sql
SELECT [Products].[Product Name], [Categories].[Category Name]
FROM [Products] INNER JOIN [Categories]
ON [Products].[Category ID] = [Categories].[Category ID];
```

When a data set is returned in answer to a query, the SQL engine uses column names from the originating tables in the data set returned. If we want a different column name or a name isn’t implied by the expression used to generate the column, we can use column aliases. The following example renames the returned column "Birth Date" to just "Birth":

```sql
SELECT [Birth Date] AS [Birth] FROM [Employees];
```

The AS keyword is optional so we might rewrite the above query as:

```sql
SELECT [Birth Date] [Birth] FROM [Employees];
```

However, because of the clarity the AS keyword brings to a query it is madness not to use it. Keep in mind that queries we write today might not be so obvious in intent when we reread them in the future.

In addition to providing alternate names for columns, we could also provide alternate names for tables. This can be useful for shortening expressions inside the query and for handling complex joins. The following example displays the name of the category for each product shortening the names of the involved tables for clarity:

```sql
SELECT [P].[Product Name], [C].[Category Name]
ON [P].[Category ID] = [C].[Category ID];
```

Whenever we write queries that return ambiguous or duplicate column or table names, we must use aliases to provide alternate names.

The TABLE variant of the SELECT statement returns all data in a given table. The following statements are equivalent:

```sql
SELECT * FROM [Employees];
TABLE [Employees];
```

The VALUES variant of the SELECT statement synthesizes a table from the supplied values and is typically used with INSERT INTO or with sub-queries. The following statement synthesizes a table with a single row and two columns with values 1 and "ABC" (note the use of the concatenation operator in the second value):

```sql
VALUES (1, "AB" & "C");
```
The WHERE, UNION, and other components of the SELECT statement restrict and organize the returned data. For more information, see the Help topic for the component being using.

**Examples**

Select the "Product Name," and "Unit Price" columns of all records in the "Products" table:

```sql
SELECT [Product Name], [Unit Price] FROM [Products];
```

Count the total number of products and name the returned column "Total Products":

```sql
SELECT Count(*) AS [Total Products] FROM [Products];
```

Show the minimum, maximum, and average prices for products:

```sql
SELECT Min([Unit Price]) AS [Min Price], Max([Unit Price]) AS [Max Price],
Avg([Unit Price]) AS [Avg Price] FROM [Products];
```

Create a table with one record and three integer columns with values 1, 2, 3:

```sql
VALUES (1, 2, 3)
```

Create a table with one integer column and three records with values 1, 2, 3:

```sql
VALUES (1), (2), (3)
```

Create a table with three records, an integer column and a text column:

```sql
VALUES (1, "a"), (2, "b"), (3, "c")
```

Create a table with two integer columns named "x" and "y" and three records:

```sql
VALUES (1, 1), (2, 2), (3, 3) NAMES (x, y)
```

**See Also**

ALL, DISTINCT, SKIP, TOP Quantifiers
**SELECT INTO Statement**

Selects data from existing tables or queries into a new table.

**Syntax**

```
SELECT [ALL | DISTINCT | DISTINCTROW | TOP n [PERCENT]]
column [, column ...]
INTO tableNew FROM table [, table ...]
[WHERE ...] [SPLIT BY ...] [LEAVING ...] [GROUP BY ...]
[HAVING ...] [ORDER BY...]
```

The SELECT INTO statement has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>The number of records or percent in TOP or TOP PERCENT</td>
</tr>
<tr>
<td>column</td>
<td>The name of a column or an asterisk, possibly qualified with the name of a table as in [Table].[Column], or [Table]*, or an expression. Can include an alias. A non-qualified asterisk selects all columns, and must be the only item in the column list.</td>
</tr>
<tr>
<td>table</td>
<td>The name of the table containing the data (with a possible alias, and column filter), or another query, or several tables or queries joined together with one of the join operators.</td>
</tr>
<tr>
<td>tableNew</td>
<td>The name of the table to be created (must conform to standard naming conventions). If the name of the new table is the same as the name of an existing table, the statement fails.</td>
</tr>
</tbody>
</table>

**Remarks**

We can use SELECT INTO queries to archive records, make backup copies of our tables, or make snapshots of complex or frequently-changing data for reports. For example, we could produce a Monthly Sales by Region report by running the same SELECT INTO query each month.

When we use SELECT INTO to create a new table, the columns in the new table inherit the data type and size, the formatting, and the transfer rules of each column in the original tables.

To add data to an existing table, use the INSERT INTO statement.

To find out which records will be selected before we run the SELECT INTO query, we can first examine the results of a SELECT statement that uses the same selection criteria.

The SELECT INTO statement is an action query and cannot be used from within the Manifold ODBC driver.

**Example**

Select all records in the "Employees" table and copies them into a new table named "Backup Copy":

```
SELECT * INTO [Backup Copy] FROM [Employees];
```
TRANSFORM Statement
Selects data from one or more tables or queries grouping it with a specified pivot expression.

Syntax
TRANSFORM aggregate query PIVOT expression [IN list];

The TRANSFORM statement has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aggregate</td>
<td>An aggregate function that operates on the selected data.</td>
</tr>
<tr>
<td>query</td>
<td>A SELECT query with a GROUP BY clause.</td>
</tr>
<tr>
<td>expression</td>
<td>An expression used to group records.</td>
</tr>
<tr>
<td>list</td>
<td>A list of values allowed for the grouping expression.</td>
</tr>
</tbody>
</table>

Remarks
Use the TRANSFORM statement to group records by a pivot expression and to compute an aggregate function in each group.

Use the TRANSFORM statement with a query that includes the GROUP BY clause to establish two independent sets of groups and to compute an aggregate function in the records defined by the intersection of these sets of groups. The TRANSFORM statement splits each group returned by the GROUP BY clause into subgroups using a pivot expression, computes an aggregate function in each subgroup, and composes the computed values into a record for this group.

We can restrict the number of groups created by the pivot expression by supplying a list of possible values for this expression. Omitting a list of possible values will create a group for each different value of the expression.

Examples
This example uses the TRANSFORM statement to show the number of products in each category for each supplier:

TRANSFORM Count(*) SELECT [Supplier ID] FROM [Products] GROUP BY [Supplier ID] PIVOT [Category ID];

This example is similar to the example above but displays the name of each category and each supplier instead of their IDs:

TRANSFORM Count(*) SELECT [Company Name] FROM ([Products] INNER JOIN [Categories] ON [Categories].[Category ID] = [Products].[Category ID]) INNER JOIN [Suppliers] ON [Suppliers].[Supplier ID] = [Products].[Supplier ID] GROUP BY [Company Name] PIVOT [Category Name];

This example is similar to the example above but restricts product categories to beverages and seafood:

TRANSFORM Count(*) SELECT [Company Name] FROM ([Products] INNER JOIN [Categories] ON [Categories].[Category ID] = [Products].[Category ID]) INNER JOIN [Suppliers] ON [Suppliers].[Supplier ID] = [Products].[Supplier ID] GROUP BY [Company Name] PIVOT [Category Name] IN ("Beverages", "Seafood");

This example uses the TRANSFORM statement to show the number of orders taken by each employee for each calendar quarter of 1992:
TRANSFORM Count(*) SELECT [First Name] & " " & [Last Name] AS [Name] FROM [Employees] INNER JOIN [Orders] ON [Orders].[Employee ID] = [Employees].[Employee ID] WHERE Year([Order Date]) = 1992 GROUP BY [First Name] & " " & [Last Name] PIVOT "Q" & DatePart("q", [Order Date]);

This example uses the TRANSFORM statement to show the total dollar amount of orders taken by each employee for each calendar quarter of 1992:

TRANSFORM Sum([Unit Price] * [Quantity]) SELECT [First Name] & " " & [Last Name] AS [Name] FROM [Employees] INNER JOIN ([Orders] INNER JOIN [Order Details] ON [Order Details].[Order ID] = [Orders].[Order ID]) ON [Orders].[Employee ID] = [Employees].[Employee ID] WHERE Year([Order Date]) = 1992 GROUP BY [First Name] & " " & [Last Name] PIVOT "Q" & DatePart("q", [Order Date]);
**UPDATE Statement**

Changes values in columns in a specified table or query.

**Syntax**

```
UPDATE table SET column = {expression | DEFAULT} [, column = {expression | DEFAULT} ...] [WHERE ...]
```

The UPDATE statement has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>The name of the table or query containing the data we want to modify.</td>
</tr>
<tr>
<td>column</td>
<td>The name of the column we want to modify.</td>
</tr>
<tr>
<td>expression</td>
<td>An expression with which to replace the old value. Can be a query that returns a single value.</td>
</tr>
</tbody>
</table>

**Remarks**

The UPDATE statement is especially useful when we want to change many records or when the records that we want to change are in multiple tables. If the records we want to change are in multiple tables, we create a SELECT query joining these tables together with UNION, and then use the UPDATE query against the SELECT.

Use the DEFAULT keyword to set the column to its default value.

If the result of the expression on the right side of the assignment operator is NULL, the value in the respective column is left unchanged.

We can change several columns at the same time. The following example increases the unit price by 10 percent and the reorder level by 50 for products with low number of units in stock:

```
UPDATE [Products] SET [Unit Price] = [Unit Price] * 1.1,
[Reorder Level] = [Reorder Level] + 50
WHERE [Units In Stock] <= 3;
```

The UPDATE statement is an action query and cannot be used from within the Manifold ODBC driver.

**Important**

After we update records using an UPDATE query, we can't undo the operation. If we want to know which records were updated, we first examine the results of a SELECT query that uses the same criteria, and then run the update query.

Maintain backup copies of data at all times. If we update the wrong records, we can retrieve them from our backup copies.

**Example**

This example changes values in the "Reports To" column to 5 for all employee records that currently have "Reports To" values of 2:

```
UPDATE [Employees] SET [Reports To] = 5 WHERE [Reports To] = 2;
```
Suppose you have a table named "Places" with "Name" and "Population" columns, and a table named "Births" with "Place," and "Births" columns, and you want to add "Births" from the "Births" table into the relevant record in the "Places" table.

To do this, use the following query:

```
UPDATE [Places] SET [Population] = [Population] + (SELECT Sum([Births]) FROM [Births] WHERE [Name] = [Place]);
```

**Tech Tip**

UPDATE queries support use of table name aliases.

**Clauses and Operators**

**ALL, ANY, SOME Quantifiers**

Determine if the value of an expression is equal to any or all values in a specified list.

**Syntax**

```
value comparison {ALL | ANY | SOME} list
```

The ALL, ANY, and SOME quantifiers have these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>An expression for the value of interest. This can be</td>
</tr>
<tr>
<td></td>
<td>either a numeric, date or string value, or a record.</td>
</tr>
<tr>
<td>comparison</td>
<td>A comparison operator (&lt;, &lt;=, &gt;, &gt;=, =, or &lt;&gt;).</td>
</tr>
<tr>
<td>list</td>
<td>A list of values or a query.</td>
</tr>
</tbody>
</table>

**Remarks**

Use the ALL quantifier to check if the value of interest is less than (or greater than, depending on the comparison operator) all values in a list.

Use the ANY or SOME quantifier, which are synonymous, to check if the value of interest is less than (or, say, greater than, depending on the comparison operator) any of the values in a list.

**Examples**

This example uses the ALL quantifier to select orders for which freight is greater than that of any order in 1994:

```
SELECT * FROM [Orders] WHERE [Freight] > ALL (SELECT [Freight] FROM [Orders] WHERE Year([Order Date]) = 1994);
```

This example uses the ANY quantifier to select orders for which freight is more than ten thousand times greater than that of any order in 1994 except those with zero freight. Note that unlike the above query, this query can not be reworked to use an aggregate function instead of a quantifier:

```
SELECT * FROM [Orders] WHERE [Freight] * 0.0001 > ANY (SELECT [Freight] FROM [Orders] WHERE Year([Order Date]) = 1994 AND [Freight] > 0);
```
This example uses the ANY quantifier to select all customers from France or Austria. The quantifier can be replaced with the IN operator:

```
SELECT * FROM [Customers] WHERE [Country] = ANY (VALUES ("France"), ("Austria"));
```

This example uses the ANY quantifier to select all employees who served at least one customer from the employee's country and city of origin:

```
SELECT * FROM [Employees] WHERE ([Country], [City]) = ANY (SELECT [Customers].[Country], [Customers].[City] FROM [Customers] INNER JOIN [Orders] ON [Orders].[Customer ID] = [Customers].[Customer ID] WHERE [Orders].[Employee ID] = [Employees].[Employee ID]);
```

See Also

ALL, DISTINCT, SKIP, TOP Quantifiers
ALL, DISTINCT, SKIP, TOP Quantifiers
Specify records returned by a query.

Syntax

See the SELECT statement.

Remarks

Use the ALL quantifier to return all records that meet the conditions in a query. If the query does not contain any quantifiers, the ALL quantifier is assumed. The following two examples are equivalent and return all records in the "Employees" table:

```
SELECT * FROM [Employees];
SELECT ALL * FROM [Employees];
```

Use the DISTINCT quantifier to omit records that contain duplicate data in the selected columns.

The DISTINCTROW quantifier is identical to the DISTINCT quantifier.

Use the TOP quantifier to return a certain number or a certain percentage of records that meet the conditions in a query. The TOP quantifier is typically used with an ORDER BY clause that orders records returned by the query by values in one or more columns.

Use the SKIP quantifier to skip a certain number or a certain percentage of records that meet the conditions in a query. Similarly to the TOP quantifier, the SKIP quantifier is typically used with an ORDER BY clause that orders records returned by the query by values in one or more columns. Using a combination of the SKIP and TOP quantifiers provides an easy way to "page" through query records.

The number or the percentage of records used by the TOP and SKIP quantifiers can be parameterized using the PARAMETERS declaration.

Examples

This example uses the DISTINCT quantifier to select all different titles of employees:

```
SELECT DISTINCT [Title] FROM [Employees];
```

This example uses the DISTINCT quantifier to select all types of discounts made on products (note that the DISTINCT quantifier leaves different discounts made on the same product as well as different products offered at the same discount):

```
SELECT DISTINCT [Product Name], [Discount] FROM [Products] INNER JOIN [Order Details] ON [Products].[Product ID] = [Order Details].[Product ID];
```

This example uses the TOP quantifier to select 5 products with highest prices:

```
SELECT TOP 5 * FROM [Products] ORDER BY [Unit Price] DESC;
```

This example uses the TOP quantifier to select 10% of products with the lowest amount of units in stock:

```
SELECT TOP 10 PERCENT * FROM [Products] ORDER BY [Units In Stock];
```

This example uses the SKIP quantifier to select all but the 5 products with highest prices:
SELECT SKIP 5 * FROM [Products] ORDER BY [Unit Price] DESC;

This example uses the SKIP and TOP quantifiers to select the second 10% of products (that is, between 10% and 20%) with the lowest amount of units in stock:

SELECT SKIP 10 PERCENT TOP 10 PERCENT * FROM [Products]
ORDER BY [Units In Stock];

This example uses a parameterized version of the TOP quantifier to select a user-specified number of products with the lowest amount of units in stock:

PARAMETERS [Number of Products] INTEGER;
SELECT TOP [Number of Products] * FROM [Products] ORDER BY [Units In Stock];

ALL, ANY, SOME Quantifiers
PARAMETERS Declaration
BETWEEN AND Operator
Determines whether the value of an expression falls within a specified range of values.

Syntax

value [NOT] BETWEEN value AND value

The BETWEEN AND operator syntax has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>An expression for the value of interest, and expressions giving the bounds for this value. This can be either a numeric, date or string value, or a record.</td>
</tr>
</tbody>
</table>

Remarks

If the value of interest is greater than or equal to the first bound and less than or equal to the second bound, the operator returns True; otherwise, it returns False. Therefore, if the first bound is greater than the second bound, the operator will always return False. We can include the NOT operator to evaluate the opposite condition (that is, whether the value lies outside the range defined by the given bounds).

We can use the BETWEEN AND operator with numbers, strings, dates, but not binaries.

If any of the values is NULL, the BETWEEN AND operator also returns NULL.

We can use the BETWEEN AND operator with records that have the same number of columns of compatible types. The records are compared from the leftmost column to the rightmost column. We can also construct records using lists of values.

Examples

This example uses the BETWEEN AND operator to select all orders made between the 1st of June, 1991 and the 30th of June, 1991:

```
```

This example uses the BETWEEN AND operator to select all products with unit price between 10 and 14.95 dollars (inclusive):

```
SELECT * FROM [Products] WHERE [Unit Price] BETWEEN 10 AND 14.95;
```

This example uses the BETWEEN AND operator to select all customers whose name starts with a letter E, F, G, H, or I:

```
SELECT * FROM [Customers] WHERE UCase(Left([Contact Name], 1)) BETWEEN "E" AND "I";
```

This example uses the BETWEEN AND operator to select all orders in the 1992 between March and May:

```
SELECT * FROM [Orders] WHERE (Year([Order Date]), Month([Order Date])) BETWEEN (1992, 3) AND (1992, 5);
```
CASE Operator
Returns a value depending on a set of conditions.

Syntax

CASE value WHEN value THEN value [WHEN value THEN value ...] [ELSE value] END

or

CASE WHEN condition THEN value [WHEN condition THEN value ...] [ELSE value] END

The CASE operator has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>The examined value, the example value, or the returned value.</td>
</tr>
<tr>
<td>condition</td>
<td>The examined Boolean expression.</td>
</tr>
</tbody>
</table>

Remarks

Use the first form of the CASE operator to translate a value to another value. A common use of the CASE operator is to replace codes or abbreviations with more readable values or vice versa. When used in the first form, the operator checks the examined value against the values in the WHEN clauses in the order they appear in the operator, and if the examined value is equal to that in a WHEN clause, the operator returns the value in the corresponding THEN clause. If the examined value is not equal to that in any WHEN clause, the operator returns the value in the ELSE clause, or NULL if the ELSE clause is omitted.

Use the second form of the CASE operator to evaluate one or more conditions and return a value depending on the results of the evaluation. When used in the second form, the operator evaluates the conditions in the WHEN clauses in the order they appear in the operator, and if a condition evaluates to True, returns the value in the corresponding THEN clause. If none of the conditions returns True, the operator returns the value in the ELSE clause, or NULL if the ELSE clause is omitted.

Examples

This example uses the CASE operator to report a home country for each employee, replacing "UK" with "United Kingdom," and "USA" with "United States of America":

```
SELECT [First Name], [Last Name], CASE [Country] WHEN "UK" THEN "United Kingdom" WHEN "USA" THEN "United States of America" ELSE [Country] END AS [Country] FROM [Employees];
```

This example uses the CASE operator to classify the order date of each order into seasons:

```
SELECT [Orders].*, CASE WHEN Month([Order Date]) BETWEEN 3 AND 5 THEN "Spring" WHEN Month([Order Date]) BETWEEN 6 AND 8 THEN "Summer" WHEN Month([Order Date]) BETWEEN 9 AND 11 THEN "Autumn" ELSE "Winter" END AS [Order Season] FROM [Orders];
```

This example uses the CASE operator to classify the freight of each order into "high," "medium," and "low" classes:

```
SELECT [Orders].*, CASE WHEN [Freight] >= 200 THEN "High" WHEN [Freight] >= 50 THEN "Medium" WHEN [Freight] > 0 THEN "Low" END AS [Freight Class] FROM [Orders];
```
CAST Operator
Explicitly casts the given value to another type.

Syntax

CAST(value AS type)

The CAST operator has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>The value of interest.</td>
</tr>
<tr>
<td>type</td>
<td>The target type.</td>
</tr>
</tbody>
</table>

Remarks

Use the CAST operator to explicitly cast a value to another type. For the list of supported types, see the Data Types topic.

The CAST operator works like CDbl, CInt, CStr and other similar functions but allows using the explicit name of the type.

Examples

This example uses the CAST operator to select the rounded price of each product:

```
SELECT [Product Name], CAST([Unit Price] AS INT) AS [Rounded Price] FROM [Products];
```

This example uses the CAST operator and the IS NULL operator to select all employees with numeric postal codes:

```
SELECT * FROM [Employees] WHERE CAST([Postal Code] AS INT) IS NOT NULL;
```

We might use the above example in situations where we would like to differentiate between employees with numeric postal codes (as in the case of ZIP codes in the US, which contain only numbers) and those with postal codes that use both letters and numbers (as in the case of Canadian or UK postal codes).
CROSS JOIN Operator
Combines records from two tables without any conditions.

Syntax

table CROSS JOIN table

The CROSS JOIN operator has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>The names of the tables from which records are combined.</td>
</tr>
</tbody>
</table>

Remarks

A CROSS JOIN operator is analogous to an INNER JOIN operator without a condition.

A CROSS JOIN operator is frequently used with a WHERE clause that filters the resulting records using criteria that would be not be used within an INNER JOIN.

A CROSS JOIN operator is also frequently used with the same table. In this case, it is often necessary to provide an alternate name for one of the copies of the table, so that the names of columns in the two copies of the table are no longer ambiguous.

Example

This example uses the CROSS JOIN operator and a WHERE clause to select the orders that were shipped later than those orders made after them (the DISTINCT operator collapses records for the same order into one record):

```sql
WHERE [Orders].[Order Date] < [Copy].[Order Date] AND [Orders].[Shipped Date] > [Copy].[Shipped Date];
```
EXCEPT Operator

Filters the results of one query or table so that it does not include the results of another query or table.

Syntax

```
query EXCEPT [ALL] query
```

The EXCEPT operator has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>A table or a query that returns a table.</td>
</tr>
</tbody>
</table>

Remarks

We can use the EXCEPT operator to remove all records occurring in the second query or table from the results in the first query or table. The following example uses the EXCEPT operator to remove orders shipped after July 1, 1991 from orders ordered after June 1, 1991, to return all orders ordered and shipped in June, 1991:

```
```

We can chain several EXCEPT operators together to combine the results of several tables or queries. We can also chain EXCEPT operators with UNION and INTERSECT operators. The priority of the EXCEPT operator is lower than that of the INTERSECT operator, and is the same as that of the UNION operator.

By default, no duplicate records are returned when we use an EXCEPT operator; however, we can include the ALL predicate to ensure that all records are returned.

Both tables or queries used in an EXCEPT operator must have the same number of columns, which must be of compatible data types.

When using an EXCEPT operator on queries, use aliases only in the first SELECT statement because aliases used in any other SELECT statement but the first are ignored. In the ORDER BY clause, refer to columns by what they are called in the first table or query.

Examples

This example retrieves the names of all suppliers in USA who have a fax:

```
SELECT [Company Name], [Fax] FROM [Suppliers] WHERE [Country] = "USA" EXCEPT SELECT [Company Name], [Fax] FROM [Suppliers] WHERE [Fax] = ""
```

This example retrieves the names of all customers in France except those who live in Paris and those who ordered something in June, 1991:

```
```
**EXISTS Operator**
Determines if a given list of values contains at least one value.

**Syntax**

```sql
EXISTS list
```

The EXISTS operator has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>list</td>
<td>A list of values or a query.</td>
</tr>
</tbody>
</table>

**Remarks**

Use the EXISTS operator to check if a list of values is empty or not. The EXISTS operator is typically used with a query, but we could use it with a list of values, in which case the operator will always return True.

**Examples**

This example uses the EXISTS operator to show whether each particular employee has served at least one order in July (any year):

```sql
SELECT [First Name], [Last Name], EXISTS (SELECT * FROM [Orders] WHERE [Orders].[Employee ID] = [Employees].[Employee ID] AND Month([Order Date]) = 7) FROM [Employees];
```

This example uses the EXISTS operator to select only those products that have a supplier in London (this can also be done with the INNER JOIN operator):

```sql
SELECT * FROM [Products] WHERE EXISTS (SELECT * FROM [Suppliers] WHERE [Suppliers].[Supplier ID] = [Products].[Supplier ID] AND [City] = "London");
```
FROM Clause
Specifies the tables or queries that contain the data for a SELECT statement.

Syntax

FROM query [AS] alias [(column [, column ...])] [, query ...]

The FROM clause has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>A table or a query returning a table.</td>
</tr>
<tr>
<td>alias</td>
<td>An alternate name for a table or a query.</td>
</tr>
<tr>
<td>column</td>
<td>A column of a table or a query that is to be processed by the enclosing query.</td>
</tr>
</tbody>
</table>

Remarks

The order of the tables or queries in a FROM clause is not important.

We can specify an alternate name for each item in the FROM clause. The following example selects all cases of non-zero discounts on tofu using the "Order Details" and "Products" tables renaming the "Order Details" to "D," and "Products" to "P," to shorten the expressions in the INNER JOIN operator:

```sql
```

We can restrict the columns returned by each item in the FROM clause by supplying a list of desired columns after the item. The following example restricts data selected from the "Employees" table to only the first names and last names:

```sql
SELECT * FROM [Employees] ([First Name], [Last Name]);
```

Editing the column list to replace the asterisk with the names of the relevant columns would achieve the same result:

```sql
SELECT [First Name], [Last Name] FROM [Employees];
```

The difference between the above queries is that the first query filters the columns before they are available for the rest of the query, and the second query filters the columns after they have been processed by the rest of the query. Hence, the first of the modifications below will not work but the second will:

```sql
[Incorrect] SELECT * FROM [Employees] ([First Name], [Last Name]) WHERE [Employee ID] > 10;
```

```sql
[Correct] SELECT [First Name], [Last Name] FROM [Employees] WHERE [Employee ID] > 10;
```

Examples

This example selects the names and descriptions of all product categories using the FROM clause to restrict the data in the "Categories" table to only the desired columns:

```sql
SELECT * FROM [Categories] ([Category Name], [Description]);
```
This example selects orders to Caracas using the FROM clause to restrict the data in the "Orders" table to only the columns used by the query, and then using the column list to further restrict the data to only the output columns:

```
SELECT [Order Date], [Freight] FROM [Orders] ([Order Date], [Freight], [Ship City]) WHERE [Ship City] = "Caracas";
```
GROUP BY Clause
Combines records with identical values in the specified column or columns into a single record.

Syntax

GROUP BY expression [, expression ...]

The GROUP BY clause has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression</td>
<td>The expression used for grouping. Can be a column name.</td>
</tr>
</tbody>
</table>

Remarks

Use the GROUP BY clause to group all records with the same value of one or more expressions into a single record.

We use the WHERE clause to exclude rows we do not want grouped, and we use the HAVING clause to filter records after they’ve been grouped.

We can not group records using binary columns.

When the GROUP BY clause is used, each item in the column list must either be exactly equal to one of the grouping expressions, or be an aggregate function, such as Sum or the Avg function.

Examples

This example uses the GROUP BY clause to create a list of unique job titles and the number of employees with each title:

```sql
SELECT [Title], Count(*) AS [Number of Employees] FROM [Employees] GROUP BY [Title];
```

This example uses the GROUP BY clause to compute the minimum, maximum, and total freight of orders for each customer:

```sql
SELECT [Customer ID], Min([Freight]) AS [Minimum], Max([Freight]) AS [Maximum], Sum([Freight]) AS [Total] FROM [Orders] GROUP BY [Customer ID];
```

This example is similar to the above, but uses the INNER JOIN operator to report the name of the customer instead of the customer ID:

```sql
SELECT [Company Name], Min([Freight]) AS [Minimum], Max([Freight]) AS [Maximum], Sum([Freight]) AS [Total] FROM [Orders] INNER JOIN [Customers] ON [Customers].[Customer ID] = [Orders].[Customer ID] GROUP BY [Company Name];
```

This example uses the GROUP BY clause to compute the number of orders shipped in one, two, three or other number of days:

```sql
SELECT DateDiff("d", [Shipped Date], [Order Date]) AS [Shipment Days], Count(*) AS [Number of Orders] FROM [Orders] GROUP BY DateDiff("d", [Shipped Date], [Order Date]);
```
HAVING Clause
Filters records grouped by the GROUP BY clause.

Syntax

HAVING condition

The HAVING clause has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>condition</td>
<td>A Boolean expression that determines which grouped records to display.</td>
</tr>
</tbody>
</table>

Remarks

Use the HAVING clause to filter the records after they have been grouped by the GROUP BY clause. The HAVING clause is similar to the WHERE clause, which determines which records are selected, but the WHERE clause operates before the records are grouped, and the HAVING clause operates after that.

If we use the HAVING clause without the GROUP BY clause, the entire table is considered as a single group, and the resulting table has either one record or no records, depending on whether the HAVING clause returns True or False.

Examples

This example uses the GROUP BY clause, the HAVING clause, and the WHERE clause to select the job titles assigned to more than one employee in the Washington region. The WHERE clause restricts the employees to the Washington region, and the HAVING clause restricts the titles to those assigned to more than one employee:

```sql
SELECT [Title], Count(*) as [Total] FROM [Employees] WHERE [Region] = "WA"
GROUP BY [Title] HAVING Count(*) > 1;
```

This example uses the GROUP BY clause and the HAVING clause to select total freight per year for years 1993 and later:

```sql
SELECT Sum([Freight]) AS [Total], Year([Order Date]) AS [Year] FROM [Orders]
GROUP BY Year([Order Date]) HAVING Year([Order Date]) >= 1993;
```
**IN Operator**
Determines whether the value of an expression is equal to any of several values in a specified list.

**Syntax**

```
value [NOT] IN list
```

The In operator syntax has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>An expression for the value of interest. This can be either a numeric, date or string value, or a record.</td>
</tr>
<tr>
<td>list</td>
<td>A list of values or a query.</td>
</tr>
</tbody>
</table>

**Remarks**

If the value of interest is found in the list of values, the operator returns True; otherwise, it returns False. We can include the NOT operator to evaluate the opposite condition (that is, whether the value is not in the list of values).

We can use the IN operator with numbers, strings, dates, but not binaries.

We can use the IN operator with records that have the same number of columns of compatible types. We can also construct records using lists of values.

**Examples**

This example uses the IN operator to locate all orders shipped to Lancashire and Essex:

```
SELECT [Shipped Date], [Ship Region] FROM [Orders] WHERE [Ship Region] IN ('Lancashire', 'Essex');
```

This example uses the IN operator with a sub-query to locate all orders handled by the personnel in London (the sub-query can be replaced with an INNER JOIN operator):

```
```

This example uses the IN operator and a sub-query to locate all orders shipped to Finland or Denmark by Federal Shipping (as in the example above, the sub-query can be replaced with an INNER JOIN operator):

```
SELECT * FROM [Orders] WHERE ([Ship Country], (SELECT [Company Name] FROM [Shippers] WHERE [Shipper ID] = [Ship Via])) IN ('Finland', 'Federal Shipping', 'Denmark', 'Federal Shipping');
```
INNER JOIN Operator
Combines records from two tables.

Syntax

table [INNER] JOIN table ON condition

The INNER JOIN operator has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>The names of the tables from which records are combined.</td>
</tr>
<tr>
<td>condition</td>
<td>A Boolean expression restricting the records in the resulting table.</td>
</tr>
</tbody>
</table>

Remarks

We can use an INNER JOIN operator in any FROM clause. For example, we can use INNER JOIN with the "Categories" and "Products" tables to select all products in each category. In contrast, to select all categories (even if some categories have no products) or all products (even if some do not belong to any category), we need to use a LEFT JOIN or RIGHT JOIN operator to create an outer join.

The following example shows how we could join the "Categories" and "Products" tables using the "Category ID" column:

```
SELECT [Category Name], [Product Name] FROM [Categories] INNER JOIN [Products]
ON [Categories].[Category ID] = [Products].[Category ID];
```

We can use more than one column in a join condition.

We can nest JOIN statements using the following syntax:

table join (table join (table ...) ON condition) ON condition

Examples

This example uses the INNER JOIN operator to select all orders assigned to Andrew Fuller:

```
SELECT [Order ID], [Order Date] FROM [Orders] INNER JOIN [Employees]
ON [Employees].[Employee ID] = [Orders].[Employee ID] AND [Employees].[First Name]
= "Andrew" AND [Employees].[Last Name] = "Fuller";
```

The word "INNER" can be omitted, so the above query can be rewritten as:

```
SELECT [Order ID], [Order Date] FROM [Orders] JOIN [Employees]
ON [Employees].[Employee ID] = [Orders].[Employee ID] AND [Employees].[First Name]
= "Andrew" AND [Employees].[Last Name] = "Fuller";
```

This example uses nested INNER JOIN operators and GROUP BY clause to produce a list of employees and their total sales using "Employees," "Orders," and "Order Details" tables:

```
SELECT Sum([Unit Price] * [Quantity]) AS [Sales], ([First Name] & " " & [Last Name]) AS [Name] FROM [Employees] INNER JOIN ([Orders] INNER JOIN [Order Details] ON [Order Details].[Order ID] = [Orders].[Order ID])
ON [Orders].[Employee ID] = [Employees].[Employee ID]
GROUP BY [Name];
```
[Orders].[Employee ID] = [Employees].[Employee ID] GROUP BY ([First Name] & " " & [Last Name]);
INTERSECT Operator
Restricts the results of a query or table to only those results found in another query or table.

Syntax

query INTERSECT [ALL] query

The INTERSECT operator has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>A table or a query that returns a table.</td>
</tr>
</tbody>
</table>

Remarks

We can use the INTERSECT operator to remove all records not found in the second query or table from the results of the first query or table. The following example uses the INTERSECT operator to restrict orders ordered after June 1, 1991 to only those orders shipped before July 1, 1991, to return all orders ordered and shipped in June, 1991:

```sql
```

We can chain several INTERSECT operators together to combine the results of several tables or queries. We can also chain INTERSECT operators with UNION and EXCEPT operators. The priority of the INTERSECT operator is higher than the priority of UNION and EXCEPT operators.

By default, no duplicate records are returned when we use an INTERSECT operator; however, we can include the ALL predicate to ensure that all records are returned.

Both tables or queries used in an INTERSECT operator must have the same number of columns, which should be of compatible data types.

When using an INTERSECT operator on queries, use aliases only in the first SELECT statement because aliases used in any other SELECT statement but the first are ignored. In the ORDER BY clause, refer to columns by what they are called in the first table or query.

Examples

This example retrieves the names of all employees in the US who were hired in 1992 or later:

```sql
SELECT [First Name], [Last Name] FROM [Employees] WHERE [Country] = "USA" INTERSECT SELECT [First Name], [Last Name] FROM [Employees] WHERE [Hire Date] >= #1/1/1992#;
```

This example retrieves the names of all customers in France (__) who placed orders in June, 1991, except those who live in Paris:

```sql
```

The parentheses around EXCEPT make the query engine first locate all customers from France, then remove those customers living in Paris, and then leave the customers who placed orders in June, 1991. Omitting the parentheses would make the query engine first locate all customers who live in Paris, then leave those customers who placed orders in June, and then subtract them from all the customers in France, which would obviously lead to a different result.
IS Operator
Checks whether a given Boolean value is True, False, or unknown.

Syntax

\[ \text{value IS [NOT] \{TRUE | FALSE | UNKNOWN\}} \]

The IS operator has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>The value of interest</td>
</tr>
</tbody>
</table>

Remarks

Use the IS operator to check if the Boolean value is True, False, or unknown. The unknown value can occur as a combination of a True or False and a NULL, for example, True AND NULL is unknown. Note that some combinations of a True and a False and a NULL are not unknown, for example, True OR NULL is True.

The following table lists the logical rules used by the NOT operator:

<table>
<thead>
<tr>
<th>Expression</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOT True</td>
<td>False</td>
</tr>
<tr>
<td>NOT False</td>
<td>True</td>
</tr>
<tr>
<td>NOT Unknown</td>
<td>Unknown</td>
</tr>
</tbody>
</table>

The following table lists the logical rules used by the AND operator:

<table>
<thead>
<tr>
<th>AND True</th>
<th>AND False</th>
<th>AND Unknown</th>
</tr>
</thead>
<tbody>
<tr>
<td>True</td>
<td>False</td>
<td>Unknown</td>
</tr>
<tr>
<td>False</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>Unknown</td>
<td>False</td>
<td>Unknown</td>
</tr>
</tbody>
</table>

For example, False AND Unknown results in False.

The following table lists the logical rules used by the OR operator:

<table>
<thead>
<tr>
<th>OR True</th>
<th>OR False</th>
<th>OR Unknown</th>
</tr>
</thead>
<tbody>
<tr>
<td>True</td>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>False</td>
<td>True</td>
<td>Unknown</td>
</tr>
<tr>
<td>Unknown</td>
<td>Unknown</td>
<td>Unknown</td>
</tr>
</tbody>
</table>

For example, False OR Unknown results in Unknown.

The following table lists the logical rules used by the IS operator:

<table>
<thead>
<tr>
<th>IS True</th>
<th>IS False</th>
<th>IS Unknown</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
For example, `False IS Unknown` results in `FALSE`.

Use the IS NULL operator to check if a value (not necessarily Boolean) is NULL or not.

**Examples**

This example uses the IS operator to select all employees whose birthday falls on August:

```
SELECT * FROM [Employees] WHERE (Month([Birth Date]) = 8) IS TRUE;
```

The **IS TRUE** can always be omitted, so the above example could be rewritten as:

```
SELECT * FROM [Employees] WHERE Month([Birth Date]) = 8;
```

This example uses the IS operator to select all orders for which the order date and required date are not in the same month:

```
SELECT * FROM [Orders] WHERE (Month([Order Date]) = Month([Required Date])) IS FALSE;
```

This example uses the IS operator and a subquery to select all orders to the United Kingdom that do not include chocolate:

```
SELECT * FROM [Orders] WHERE ([Ship Country] = "UK" AND (SELECT Sum([Quantity])
```
IS NULL Operator
Checks whether the given value is NULL or not.

Syntax

value IS [NOT] NULL

The IS NULL operator has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>The value of interest.</td>
</tr>
</tbody>
</table>

Remarks

Use the IS NULL operator to check whether a value is NULL or not. The IS NULL operator is typically used with a query that returns a single record. In this case, the operator returns True if all of the values within the returned record are NULL and False otherwise. If the query returns more than one record the IS NULL operator returns True (not False!).

Examples

This example uses the IS NULL operator to select orders that were the first orders processed in that month (this also can be done with the EXISTS or INNER JOIN operators or with the Count aggregate function):

```sql
SELECT * FROM [Orders] WHERE (SELECT Min([Copy].[Order Date]) FROM [Orders] AS [Copy] WHERE [Copy].[Order Date] < [Orders].[Order Date] AND Year([Copy].[Order Date]) = Year([Orders].[Order Date]) AND Month([Copy].[Order Date]) = Month([Orders].[Order Date])) IS NULL;
```

This example uses the IS NULL operator to select employees who have processed orders on their birthday (this also can be done with the EXISTS or INNER JOIN operators or with the Count aggregate function):

```sql
SELECT * FROM [Employees] WHERE (SELECT Min([Orders].[Order ID]) FROM [Orders] WHERE [Orders].[Employee ID] = [Employees].[Employee ID] AND Month([Order Date]) = Month([Birth Date]) AND Day([Order Date]) = Day([Birth Date])) IS NOT NULL;
```
LEAVING Clause
Filters records exploded by the SPLIT BY clause.

Syntax

LEAVING condition

The LEAVING clause has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>condition</td>
<td>A Boolean expression that determines which exploded records to display.</td>
</tr>
</tbody>
</table>

Remarks

Use the LEAVING clause to filter the records after they have been exploded by the SPLIT BY clause. The LEAVING clause is similar to the WHERE clause, which determines which records are selected, but the WHERE clause operates before the records are exploded and the LEAVING clause operates after that.

The LEAVING clause cannot be used without the SPLIT BY clause.

Examples

This example uses the SPLIT BY clause and the LEAVING clause to select all islands in areas in drawing D the area of which exceeds 10 miles:

```
SELECT [I], Area([I], "mi") FROM [D]
SPLIT BY Islands([ID]) AS [I]
LEAVING Area([I], "mi") > 10;
```

This example uses the SPLIT BY clause and the LEAVING clause to select all coordinates in objects in drawing D the X coordinates of which are between -1000 and 1000:

```
SELECT [P] FROM [D]
SPLIT BY Coords([ID]) AS [P]
LEAVING CentroidX([P]) BETWEEN -1000 AND 1000;
```

This example uses the SPLIT BY clause and the LEAVING clause to select all coordinates in objects in drawing D which are within 1 mile of the object centroid:

```
SELECT [P] FROM [D]
SPLIT BY Coords([ID]) AS [P]
LEAVING Distance([P], Centroid([ID]), "mi") < 1;
```

See Also

SPLIT BY Clause
WHERE Clause
LIKE Operator
Checks if a string value matches a given pattern.

Syntax

expression [NOT] LIKE expression

The LIKE operator has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression</td>
<td>The value of interest and a pattern.</td>
</tr>
</tbody>
</table>

Remarks

Use the LIKE operator to check if a string value matches a given pattern. If a value matches a pattern, the operator returns True; otherwise, it returns False.

In a pattern, use the underscore character (_) to match any single character. Use the percent sign (%) to match any number of characters including zero. Use the backslash character and the underscore character (\_) to match the underscore character, use the backslash character and the percent sign (\%) to match the percent sign, use two backslash characters (\\) to match the backslash character. Use any other character, like a letter or a digit, to match itself.

The LIKE operator is case-sensitive. To match values without case, convert both the string and the pattern to either upper or lower case with UCase or LCase.

If either the checked value or the pattern is NULL, the LIKE operator also returns NULL.

Examples

The following table shows sample expressions using the LIKE operator and the value returned by each expression:

<table>
<thead>
<tr>
<th>String Expression</th>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>abbc LIKE a%</td>
<td>TRUE</td>
</tr>
<tr>
<td>abbc LIKE _c</td>
<td>FALSE</td>
</tr>
<tr>
<td>abbc LIKE %c</td>
<td>TRUE</td>
</tr>
<tr>
<td>abbc LIKE %bb</td>
<td>FALSE</td>
</tr>
<tr>
<td>a_bc LIKE %</td>
<td>TRUE</td>
</tr>
<tr>
<td>a_bc LIKE a_bc</td>
<td>TRUE (because _ matches any character)</td>
</tr>
<tr>
<td>a_bc LIKE a_bc</td>
<td>TRUE (because \ matches _)</td>
</tr>
<tr>
<td>a_bc LIKE a_c</td>
<td>TRUE</td>
</tr>
<tr>
<td>ab\c LIKE %%</td>
<td>FALSE</td>
</tr>
<tr>
<td>ab\c LIKE %%</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

This example uses the LIKE operator to select all products the name of which starts with "C":

    SELECT * FROM [Products] WHERE [Product Name] LIKE "C%";
This example uses the LIKE operator to select all products the name of which ends with "n":

```sql
SELECT * FROM [Products] WHERE [Product Name] LIKE "%n";
```

This example uses the LIKE operator to select all customers whose contact title includes the word "sales" (ignoring case):

```sql
SELECT * FROM [Customers] WHERE LCase([Contact Title]) LIKE "%sales%";
```

This example uses the LIKE operator to select all customers whose phone number contains a non-empty area code in parentheses:

```sql
SELECT * FROM [Customers] WHERE [Phone] LIKE "%(_%)%";
```

This example uses the LIKE operator and the PARAMETERS declaration to locate all customers whose company name matches a pattern supplied as a parameter:

```sql
PARAMETERS [Pattern] TEXT;
SELECT * FROM [Customers] WHERE [Company Name] LIKE [Pattern];
```
**LIKEX Operator**
Checks if a string value matches a given pattern using regular expressions.

**Syntax**

```
expression [NOT] LIKEX expression
```

The LIKEX operator syntax has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression</td>
<td>The value of interest and a pattern.</td>
</tr>
</tbody>
</table>

**Remarks**

Use the LIKEX operator to check if a string value matches a given pattern. If the value matches the pattern, the operator returns True; otherwise, it returns False.

For syntax that may be used in the pattern see the Regular Expressions topic.

If either the checked value or the pattern is NULL, the LIKEX operator also returns NULL.

**Examples**

This example uses the LIKEX operator to select all products whose name contains "'s" at the end of the word that is not the last word:

```
SELECT * FROM [Products] WHERE [Product Name] LIKEX ".+'s .+";
```

This example uses the LIKEX operator to select all customers whose phone contains three-digit area code:

```
SELECT * FROM [Customers] WHERE [Phone] LIKEX ".*\(\d{3}\).*";
```

This example uses the LIKEX operator to select all customers whose company names consist of at least three words:

```
SELECT * FROM [Customers] WHERE [Company Name] LIKEX "\S* \S* \S.*";
```

This example uses the LIKEX operator to select all customers whose company name includes the word "the", ignoring the case:

```
SELECT * FROM [Customers] WHERE LCase([Company Name]) LIKEX ".*\bthe\b.*";
```
OPTIONS Clause

The OPTIONS clause allows a declaration of options for query execution and usage. At the present time, the only option for this clause is the CoordSys query function. The OPTIONS clause must be the first clause in the query, since it potentially specifies the operation of all the rest of the query.

Syntax

OPTIONS expression[, expression];

The OPTIONS clause has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression</td>
<td>An expression using the CoordSys or Precision subclauses.</td>
</tr>
</tbody>
</table>

Remarks

In Manifold, we can use a query to produce temporary results which can be treated as a drawing, image or surface. In many cases, the coordinate system and other parameters of the component imported or linked from such a query will be set to default values. The OPTIONS clause allows specifying the values of these parameters to be different from default values.

The OPTIONS clause supports the following subclauses:

- **CoordSys** - Allows specifying the coordinate system of the component represented by the query. The syntax of the CoordSys subclause is similar to that of the CoordSys function specified in the Spatial Extensions topic. The CoordSys subclause can accept a string value with the name of the coordinate system preset, or a string value with the name of the component to take the coordinate system from, followed by the AS COMPONENT construct.

- **Precision** - Allows specifying the value of the location precision parameter of the drawing represented by the query. The Precision subclause can accept a floating-point value with the value of the location precision parameter in native units, or a string value with the name of the component to take the value of the location precision parameter from, followed by the AS COMPONENT construct.

The CoordSys subclause is especially useful with queries representing images and surfaces, which typically use virtual tables for existing images or surfaces.

Consider the following two queries operating on a surface named Surface:

```
SELECT * FROM [Surface] WHERE [Height (I)] > 100;

...and...

OPTIONS CoordSys("Surface" AS COMPONENT);
SELECT * FROM [Surface] WHERE [Height (I)] > 100;
```

Both queries select all pixels with a height greater than 100. However, linking a surface from the first query will create a surface in the default Orthographic projection, since pixels do not carry coordinate system data, but linking a surface from the second query will create a surface using the coordinate system (that is, the projection) of the original surface.

The following query selects all areas (but not points or lines) from the drawing named "Drawing". Linking that query as a drawing will set the value of the location precision parameter in the new drawing to that in "Drawing":

```
OPTIONS Precision("Drawing" AS COMPONENT);
SELECT * FROM [Drawing] WHERE CStr([Type (I)]) = "Area";
```
**Example**

We have a large surface and we would like to create a query that grabs only a portion of that surface within a given latitude and longitude range. We will then create a linked surface based on the query. The result will be a surface that is only a portion of the larger surface. We will use an OPTIONS clause in the query to make sure the resulting linked surface is correctly georegistered using the same projection as the original surface. This is a common technique for Internet Map Server (IMS) applications.

We begin with a surface showing dropout rates from high school in the US (blue represents lower dropout rates, red shows higher dropout rates). This is the same surface created in the Displaying Data in a Gradient Map example. We have colored the background black and have turned on a graticule showing latitude and longitude lines every five degrees.

We write a query called **Surface Query** that selects pixels between -85 and -80 degrees longitude and between 35 and 40 degrees latitude. The OPTIONS clause will ensure that linked surface created from the query will use the same projection as the original surface.

```
OPTIONS CoordSys("Surface" AS COMPONENT);
SELECT * FROM [Surface]
WHERE ([Longitude (I)] >= -85 AND [Longitude (I)] <= -80)
   AND ([Latitude (I)] >= 35 AND [Latitude (I)] <= 40);
```

If we create a linked surface from the query we see that only that portion of the surface within the desired latitude and longitude ranges is in the linked surface.
For use in an application like an IMS website, we would probably rewrite the query used in this example as a parameter query as seen above. This would allow users to specify the minimum and maximum longitude and latitude range to get the desired portion of the surface.
**ORDER BY Clause**

Sorts records using specified criteria in ascending or descending order.

**Syntax**

```
ORDER BY expression [ASC | DESC] [, expression [ASC | DESC] ...]
```

The ORDER BY clause has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression</td>
<td>An expression with which to sort records.</td>
</tr>
</tbody>
</table>

**Remarks**

Use the ORDER BY clause to sort records using one or more expressions. The expressions can be columns, operations on columns, or literals. If the ORDER BY clause includes more than one expression, the records are sorted by the value returned by the first expression, then the records with the same value of the first expression are sorted by the value returned by the second expression, and so on.

Use a numeric expression that is a single number to sort by the value of an output column with the given index (one-based).

Use the ASC and DESC keywords to specify whether the sorting is done in ascending (ASC) or descending (DESC) order. If neither ASC nor DESC is specified, the sorting is done in ascending order.

We can sort records using numeric, date, or string expressions, but not binary expressions.

**Examples**

This example uses the ORDER BY clause to sort employees by last name in ascending order:

```
SELECT * FROM [Employees] ORDER BY [Last Name] ASC;
```

The ASC keyword is optional, so we may rewrite the above example as:

```
SELECT * FROM [Employees] ORDER BY [Last Name];
```

This example uses the ORDER BY clause to sort employees by country, and then by city:

```
SELECT * FROM [Employees] ORDER BY [Country], [City];
```

This example uses the ORDER BY clause and the INNER JOIN operator to sort orders by shipper in ascending order, and then by the number of days it took to ship the order in descending order:

```
SELECT [Company Name], [Order Date], [Shipped Date] FROM [Orders] INNER JOIN [Shippers] ON [Shipper ID] = [Ship Via] ORDER BY [Company Name], DateDiff("d", [Shipped Date], [Order Date]) DESC;
```

This example is similar to the example above, but includes the number of days it took to ship the order as the output column, and uses references to the output columns in the ORDER BY clause:

```
SELECT [Company Name], [Order Date], [Shipped Date], DateDiff("d", [Shipped Date], [Order Date]) AS [Shipment Days] FROM [Orders] INNER JOIN [Shippers] ON [Shipper ID] = [Ship Via] ORDER BY 1, 4 DESC;
```
OUTER (LEFT, RIGHT, FULL) JOIN Operators

Combine records from two tables allowing NULL values on left, right, or both sides.

Syntax

```
table {LEFT | RIGHT | FULL} [OUTER] JOIN table ON condition
```

The LEFT JOIN, RIGHT JOIN, and FULL JOIN operators have these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>The names of the tables from which records are combined.</td>
</tr>
<tr>
<td>condition</td>
<td>A Boolean expression restricting the records in the resulting table.</td>
</tr>
</tbody>
</table>

Remarks

Use a LEFT JOIN operator to create a left outer join. Left outer joins include all of the records from the first (left) of two tables, even if there are no matching values for records in the second (right) table.

Use a RIGHT JOIN operator to create a right outer join. Right outer joins include all of the records from the second (right) of two tables, even if there are no matching values for records in the first (left) table.

Use a FULL JOIN operator to create a full outer join. Full outer joins include all of the records from both tables, even if there are no matching values for records in the other table.

The following example shows how we could join the "Categories" and "Products" tables using the "Category ID" column to produce a list of all categories, including those that contain no products. The GROUP BY clause and the First aggregate function are used to collapse multiple records for products sharing the same category:

```
SELECT [Category Name], First([Product Name]) FROM [Categories] LEFT JOIN [Products] ON [Categories].[Category ID] = [Products].[Category ID] GROUP BY [Category Name];
```

The following example shows how we could join the "Categories" and "Products" tables using the "Category ID" column to produce a list of all products, including those that contain no categories:

```
SELECT [Category Name], [Product Name] FROM [Categories] RIGHT JOIN [Products] ON [Categories].[Category ID] = [Products].[Category ID];
```

To combine records disallowing NULL values on any side of a join, use an INNER JOIN operator.

We can use more than one column in a join condition.

When nesting any of the LEFT JOIN, RIGHT JOIN, and FULL JOIN operators with one or more of the INNER JOIN operators, for performance purposes it is recommended that we put LEFT JOIN, RIGHT JOIN, and FULL JOIN operators inside the INNER JOIN operators.

Examples

This example uses the LEFT JOIN operator and the GROUP BY clause to select employees and the number of orders they processed in June, 1991:

```
```
This example uses the LEFT JOIN operator, several INNER JOIN operators, and the GROUP BY clause to show whether a given product has or has not been processed at least once by Andrew Fuller:

SELECT [Product Name], "Yes" AS [Served] FROM [Products] LEFT JOIN ([Order Details] INNER JOIN ([Orders] INNER JOIN [Employees] ON [Orders].[Employee ID] = [Employees].[Employee ID] AND [First Name] = "Andrew" AND [Last Name] = "Fuller") ON [Order Details].[Order ID] = [Orders].[Order ID]) ON [Order Details].[Product ID] = [Products].[Product ID] GROUP BY [Product Name];
PARAMETERS Declaration
Declares the name and data type of each parameter in a parameter query.

Syntax

    PARAMETERS name type [(size)] [, name type [(size)] ...]

The PARAMETERS declaration has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the parameter. Use brackets ([ ]) to enclose text that contains spaces or punctuation. For example, [Low price] and [Begin report with which month?] are valid name arguments.</td>
</tr>
<tr>
<td>type</td>
<td>The type of the parameter.</td>
</tr>
<tr>
<td>size</td>
<td>The size of the parameter in characters or bytes for text or binary parameters.</td>
</tr>
</tbody>
</table>

Remarks

For queries that we run regularly, we can use a PARAMETERS declaration to create a parameter query. A parameter query can help automate the process of changing query criteria. With a parameter query, our code will need to provide the parameters each time the query is run.

The PARAMETERS declaration is optional but when included precedes any other statement.

We can use the PARAMETERS declaration with SELECT, SELECT INTO, INSERT INTO, UPDATE, DELETE, and TRANSFORM statements.

We can include more than one parameter, separating them with commas. The following example includes two parameters:

    PARAMETERS [Low price] Currency, [Beginning date] DateTime;

We can use the parameters to substitute any value within the query. We cannot, however, use the parameters to substitute names of columns or tables, or to specify functions or operators. The following example expects two parameters to be provided and then applies the criteria to records in the "Orders" table:

    PARAMETERS [Low Freight] Double, [Beginning Date] DateTime;
    SELECT [Order ID], [Order Date], [Freight] FROM [Orders] WHERE [Freight] > [Low Freight] AND [Order Date] >= [Beginning Date];

Examples

This example requires the user to provide a job title and then selects all employees with the entered title:

    PARAMETERS [Employee Title] TEXT;
    SELECT [First Name], [Last Name], [Title] FROM [Employees] WHERE [Title] = [Employee Title];

This example requires the user to provide the first characters of the employee name and then selects all employees whose first or last name starts with the entered characters:

    PARAMETERS [Name Prefix] TEXT;
SELECT [First Name], [Last Name] FROM [Employees] WHERE [First Name] LIKE [Name Prefix] & "%" OR [Last Name] LIKE [Name Prefix] & "%";
POSITION Operator
Returns the position of a string value within another string value.

Syntax

POSITION(value IN value)

The POSITION operator has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>The value of interest and the containing value.</td>
</tr>
</tbody>
</table>

Remarks

Use the POSITION operator to locate a string within another string. If the second value contains a substring that is equal to the first value the operator returns the starting location of that substring (one-based). If the second value contains several substrings equal to the first value the operator returns the starting location of the first such substring. If the second value contains no substrings equal to the first value, the operator returns 0.

The POSITION operator is case-sensitive.

Examples

This example uses the POSITION operator to select all products that typically ship in bottles:

```
SELECT * FROM [Products] WHERE POSITION("bottles" IN [Quantity Per Unit]) > 0;
```

This example uses the POSITION operator and the CAST operator to select all products the price of which is not an integer value of dollars (that is, which contains a decimal point in the price):

```
SELECT * FROM [Products] WHERE POSITION("." IN CAST([Unit Price] AS TEXT)) > 0;
```
SPLIT BY Clause
Explores records into groups of records using values in one or more columns.

Syntax

```
SPLIT BY expression[, expression ...]
```

The SPLIT BY clause has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression</td>
<td>The expression used for splitting. Must contain a call to one of the split functions or be a query.</td>
</tr>
</tbody>
</table>

Remarks

Use the SPLIT BY clause to replace each record with a group of records using one or more splitting expressions. Each splitting expression must be a query or must contain a call to one of the special split functions used to convert a single value into a set of values.

When the SPLIT BY clause includes more than one splitting expression, the records are first split with the first expression, then the result is split with the second expression, and so on in left-to-right order.

The effect of the SPLIT BY clause is the reverse of the GROUP BY clause, in that the GROUP BY clause collapses groups of records into single records, and the SPLIT BY clause explodes single records into groups of records.

It is possible to use both the SPLIT BY clause and the GROUP BY clause in the same query. In this case, the SPLIT BY clause will be applied before the GROUP BY clause.

To filter the records returned by the SPLIT BY clause, use the LEAVING clause.

Examples

This example uses the SPLIT BY clause and a query to join each area in drawing D to each point in the same drawing (one could also do this using the INNER JOIN operator):

```sql
SELECT [ID] AS [AID], [PID] FROM [D] AS [DA]
WHERE IsArea([ID]) SPLIT BY
WHERE IsPoint([DP].[ID]) AND Contains([DA].[ID], [DP].[ID]));
```

This example uses the SPLIT BY clause to output each branch of each object in drawing D as a separate geom:

```sql
SELECT [ID], [P] FROM [D]
SPLIT BY Branches([ID]) AS [P];
```

This example uses the SPLIT BY clause to create the convex hull of each area in drawing D and to output the coordinates in the hulls as separate geoms:

```sql
SELECT [ID], [P] FROM [D]
WHERE IsArea([ID])
SPLIT BY Coords(ConvexHull([ID])) AS [P];
```

This example uses the SPLIT BY clause to create a Voronoi diagram of all points in drawing D and output a Voronoi area for each point:
SELECT [P] FROM (SELECT Voronoi(AllCoords([ID]))
AS [V] FROM [D]
WHERE IsPoint([ID]))
SPLIT BY Branches([V]) AS [P];

This example is similar to the above, but uses the INNER JOIN operator to only output a Voronoi area for each point the ID of which exceeds 5:

```
SELECT [ID], [P] FROM
(SELECT [P] FROM
(SELECT Voronoi(AllCoords([ID])) AS [V] FROM [D]
WHERE IsPoint([ID]))
SPLIT BY Branches([V]) AS [P])
INNER JOIN [D] ON Contains([P], [ID])
WHERE IsPoint([ID]) AND [ID] > 5;
```

This example uses the SPLIT BY clause and the GROUP BY clause to create a table of all possible values of X in all coordinates in the drawing D, along with their frequencies:

```
SELECT CentroidX([P]), Count(*) FROM [D]
SPLIT BY Coords([ID]) AS [P]
GROUP BY CentroidX([P]);
```

**See Also**

- **GROUP BY Clause**
- **LEAVING Clause**
SUBSTRING Operator

Returns a substring from a string value.

Syntax

```
SUBSTRING(value FROM start [FOR length])
```

The SUBSTRING operator has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>The value of interest.</td>
</tr>
<tr>
<td>start</td>
<td>The starting location of the substring (one-based).</td>
</tr>
<tr>
<td>length</td>
<td>The length of the substring.</td>
</tr>
</tbody>
</table>

Remarks

Use the SUBSTRING operator to extract a substring from a string value. If the starting location or the length is less than or equal to zero the operator returns NULL. If the length parameter is omitted it is assumed to be equal to the remaining length of the string.

The SUBSTRING operator is case-sensitive.

Examples

This example uses the SUBSTRING operator to select the initials of each employee:

```
SELECT [First Name], [Last Name], SUBSTRING([First Name] FROM 1 FOR 1) & SUBSTRING([Last Name] FROM 1 FOR 1) AS [Initials] FROM [Employees];
```

This example uses the SUBSTRING operator and the POSITION operator to select the first word in the name of each product:

```
SELECT [Product Name], SUBSTRING([Product Name] FROM 1 FOR POSITION(" " IN [Product Name] & " ") - 1) AS [First Word] FROM [Products];
```
TRIM Operator
Trims characters from the left, right, or both sides of a string value.

Syntax

TRIM([[LEADING | TRAILING | BOTH] [value] FROM] value)

The TRIM operator has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>A set of characters to trim and a string value.</td>
</tr>
</tbody>
</table>

Remarks

Use the TRIM operator to trim characters from the left, right, or both sides of a string value. If the set of characters is omitted the operator trims white space characters. If no LEADING, TRAILING, or BOTH keywords are specified the operator trims both sides of the string value.

The TRIM operator is case-sensitive.

Examples

This example uses the TRIM operator to trim the building number from the address of each customer:

```sql
SELECT [Address], TRIM(TRIM("1234567890, " FROM [Address])) AS [Trimmed Address] FROM [Customers];
```

This example uses the TRIM operator to remove the first word from the title of each employee (using the English alphabet assuming the data is in English):

```sql
SELECT [Title], TRIM(TRIM(LEADING "ABCDEFGHIJKLMNOPQRSTUVWXYZabcdefghijklmnopqrstuvwxyz" FROM [Title])) AS [Trimmed Title] FROM [Employees];
```
UNION Operator

Merges the results of one query or table with another query or table.

Syntax

query UNION [ALL] query

The UNION operation has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>A table or a query that returns a table.</td>
</tr>
</tbody>
</table>

Remarks

We can use the UNION operator to merge together the results of two tables or queries. The following example uses the UNION operator to merge two SELECT statements that select data from the "Orders" table:

```
```

We can chain several UNION operators together to merge the results of several tables or queries. We can also chain UNION operators with EXCEPT and INTERSECT operators. The priority of the UNION operator is lower than that of the INTERSECT operator, and is the same as the priority of the EXCEPT operator.

By default, no duplicate records are returned when we use a UNION operator; however, we can include the ALL predicate to ensure that all records are returned.

Both tables or queries used in a UNION operator must have the same number of columns, which must be of compatible data types.

When using a UNION operator on queries, use aliases only in the first SELECT statement because aliases used in any other SELECT statement but the first are ignored. In the ORDER BY clause, refer to columns by what they are called in the first table or query.

Examples

This example retrieves the names and cities of all suppliers and customers in Brazil:

```
SELECT [Company Name], [City] FROM [Suppliers] WHERE [Country] = "Brazil" UNION SELECT [Company Name], [City] FROM [Customers] WHERE [Country] = "Brazil";
```

This example retrieves the names of all customers who either live in Brazil or whose contact is a sales manager without duplicates:

```
SELECT [Contact Name], "Lives in Brazil" AS [Reason] FROM [Customers] WHERE [Country] = "Brazil" UNION SELECT [Contact Name], "Is a Sales Manager" FROM [Customers] WHERE [Contact Title] = "Sales Manager";
```
**UNIQUE Operator**
Determines whether the given list of values contains duplicate values.

**Syntax**

```sql
UNIQUE list
```

The UNIQUE operator has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>list</td>
<td>A list of values or a query.</td>
</tr>
</tbody>
</table>

**Remarks**

Use the UNIQUE operator to check if a list of values contains duplicate values or not. If the list of values contains duplicates, the operator returns False; if the list of values does not contain duplicates, or is empty, the operator returns True. The UNIQUE operator is typically used with a query, but we could use it with a list of values.

**Examples**

This example uses the UNIQUE operator to show whether each particular employee has served the same customer more than once:

```sql
SELECT [First Name], [Last Name], UNIQUE (SELECT [Company Name] FROM [Customers] INNER JOIN [Orders] ON [Orders].[Customer ID] = [Customers].[Customer ID] WHERE [Orders].[Employee ID] = [Employees].[Employee ID]) FROM [Employees];
```

This example uses the UNIQUE operator to select only those products that were ordered only once by each customer:

```sql
```
WHERE Clause
Filters records selected by a query.

Syntax

WHERE condition

The WHERE clause has these parts:

<table>
<thead>
<tr>
<th>Part</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>condition</td>
<td>A Boolean expression that determines which records to display.</td>
</tr>
</tbody>
</table>

Remarks

Use the WHERE clause to filter records returned by a query. If the condition in the WHERE clause returns True, the record is included in the output; if it returns False, the record is excluded from the output. If the condition in the WHERE clause returns NULL, the record is excluded from the output.

In a query with a GROUP BY clause, the WHERE clause is similar to the HAVING clause in that it determines which records are selected, but the WHERE clause operates before the records are grouped, and the HAVING clause operates after records are grouped.

Examples

This example uses the WHERE clause to select employees whose last name is "King":

```
SELECT * FROM [Employees] WHERE [Last Name] = "King";
```

This example uses the WHERE clause to select orders made in July, 1992:

```
SELECT * FROM [Orders] WHERE Month([Order Date]) = 7 AND Year([Order Date]) = 1992;
```

This example uses the WHERE clause to select orders made in June or July, 1992:

```
SELECT * FROM [Orders] WHERE Month([Order Date]) IN (6, 7) AND Year([Order Date]) = 1992;
```

This example uses the WHERE clause to select orders made after June 1, 1992, that must be shipped before August 1, 1992, and that must ship to a country the name of which starts with either "F" or "U":

```
```

This example uses the WHERE clause to select orders to the UK the freight for which is greater than the average freight of all orders:

Examples

This section of the documentation sets forth step-by-step examples to help you learn Manifold. The examples in this Help system are aimed at elementary use of Manifold. We strongly urge you to repeat the examples by "following along" within Manifold.

Begin with the My First Map example and then read the other example topics in sequence. All the example topics are listed in the Examples chapter in the Help system. Get a table of contents in Help by clicking on the Show button on the Help toolbar if the tabs are hidden and then choosing the Contents tab. The Web version of this documentation might not be structured the same as the Microsoft Help version built into the installation. If you jump directly into a topic within web version you might not see the contents listing. You can always find the full web version of the documentation by going to the manifold.net web site and clicking on the User Manual link.

In addition to the step-by-step examples in the Examples chapter there are numerous small examples included throughout the rest of the documentation. The Other Examples topic provides a useful summary of the most important of these.

Visit the www.manifold.net web site from time to time and drill down into the Support pages there to check on new documentation that may be published. Advanced examples, tech support notes, scripting examples, case studies and other supplementary materials may be published on the manifold.net web site.

Files used in the Examples

Files used in the examples may be downloaded from the Product Downloads page on the manifold.net web site.

Important Configuration Notice

Very Important: Before starting Manifold, go to the Windows Control Panel Display dialog Effects tab and make sure that the Show window contents while dragging check box is not checked.

- In Windows XP this option is found in the Control Panel's Appearances and Themes - Display choice under the Appearance tab by pressing the Effects button.
- In Windows XP or Windows 2003, from the Start button open the Control panel and then open the Display dialog. Click on the Appearances tab and then press the Effects button. Uncheck the Show window contents while dragging check box.
- In Windows 2000, Windows ME and Windows 98 open the Control panel and then open the Display dialog. Click on the Effects tab, and uncheck the Show window contents while dragging check box.
- In Windows Vista, open the Control Panel and click Appearance and Personalization. Click Customize colors, then click Open classic appearance properties for more color options and click the Effects button. Uncheck the Show window contents while dragging check box.

Checking this box will greatly slow down the system when displaying complex maps and images because it forces a refresh of the window contents with each minor change in mouse position while dragging the window. Make sure the box is unchecked.

A Note for Access Users

Microsoft Access users may be familiar with the Northwind.mdb sample database provided by Microsoft with Access. The Nwind.mdb sample database provided with Manifold is a slightly earlier version of Northwind.mdb that Microsoft has authorized for redistribution. Nwind.mdb is for all practical purposes identical to the Northwind.mdb sample database distributed with Access. Access users should feel free to use either Nwind.mdb provided by Manifold or Northwind.mdb installed with Access to follow along in the examples. To avoid confusion, both versions of this database are referred to in these examples as the "Northwind" sample database.

Important Note when Using 64-bit Manifold Editions
If you have installed 64-bit Manifold, do the examples in 32-bit mode by launching Manifold System using the Manifold System (32-bit) shortcut. Some of the examples use file formats (noted below) that are not available for use in 64-bit Windows systems so they cannot be performed using Manifold in 64-bit mode. Launching Manifold in 32-bit mode will make it possible to follow along in the examples while learning Manifold.

Due to a lack of required Microsoft facilities in 64-bit Windows systems, Manifold in 64-bit mode cannot export, import, export or link to DB, HTML, MDB, XLS or WKx format files. This includes no access to the MDB parts of Manifold MFD and MapInfo TAB imports. The workaround for importing or exporting such files is to launch Manifold in 32-bit mode by using the Manifold System (32-bit) shortcut, perform the export from or import into a .map project file and then re-launch Manifold in 64-bit mode using the Manifold System (64-bit) shortcut. Linking is more complex: the data must be in some format usable in 64-bit mode within 64-bit Windows systems, such as a SQL Server database. Alternatively, the data can be kept within a Manifold .map project file and linked using the Manifold ODBC driver.

My First Map

This example creates a simple map of the San Francisco Bay region. It uses pre-existing files in MapInfo .mid/.mif format. These are provided as examples on the Manifold CD in the Examples/Help directory. Maps in MapInfo .mid/.mif format have two files per map: a .mif file and a .mid file.

It may be odd to begin an example of Manifold System usage by importing files from a different GIS system’s format, but one of the big strengths of Manifold is the ability to import data from many different formats. We will often import files from other formats for our Manifold projects.

For this example, we will use the files shown above as seen in Windows Explorer. Note that it is wise when using Windows Explorer in GIS usage to have the Windows Explorer View menu set to showing details, instead of using large cartoon icons, and to configure Explorer’s Tools - Folder Options - View options so that files are shown with three letter extensions.

If Explorer doesn’t know by default what a particular file is supposed to be it won’t show a sensible icon, and Explorer as set up by default knows nothing about common file formats in the GIS world. We can see that effect in the above illustration, where Explorer thinks that a .mid file is not part of a MapInfo .mid/.mif ensemble but rather represents a MIDI sequence file for use with Windows Media player.

Step 1: Launch Manifold

Manifold launches by default with the project pane open. The project pane shows all components (drawings, images, etc.) in the project. If the project pane is not open, we can open it with a View - Panes - Project command or with the SHIFT-ALT-P keyboard shortcut.

If the project pane is docked and we would like to undock it, we can hold down the CTRL key and then drag the pane away from its docked position. The CTRL key prevents it from docking again even if we drag it just a little bit away from the main window’s border. See the Windows topic for examples of docking and undocking.

Step 2: Import the bay_land_eg Drawing

Choose File - Import - Drawing to import a drawing.
In the *Import* file opening dialog (a standard Windows "Open" dialog), choose MIF Files (*.mif) in the Files of type box. Even though .mid/.mif files occur in pairs of files, one of which is a .mif file and one of which is a .mid file, the import dialog shows only the .mif files for clarity.

Browse over to the directory containing the sample files in the usual Windows way and double-click on the *bay_land_eg.mif* file to open it. We can also click on the file and push the *Open* button. If we wish to import more than one drawing in this dialog, we can CTRL-click on more than one file to highlight several and then press Open to import several files at once. We can also click on one file and then SHIFT-click on another to highlight all the files in between if we wish to choose several files for import.

The *Import MIF File* dialog opens to allow us to check which fields we wish to import. The *bay_land_eg.mif* file has no data attribute fields to import, but the dialog still opens. This lets us know there are no fields to import. Manifold can also import formatting from MapInfo files so this box is checked by default. The sample files on the Manifold CD have no elaborate formatting so it doesn’t matter whether we check this or not, but it is usually a good idea to leave this box checked. Click *OK*.

The import process creates a drawing component in the project pane. By default, the imported drawing is named after the file imported, but with the first letter capitalized. If we like we can change the name by right clicking on the component and choosing *Rename*. We can also click on the component, pause, and then click on it a second time to rename it in the usual Windows way.

**Step 3: Import other Drawings**

Repeat **Step 2** above to import two additional drawings: *bay_hydro_eg.mif* and *bay_roads_eg.mif*.

As these drawings are imported they appear in the project pane. These drawings show major hydrographic features and major roads.
Note that the project pane's toolbar icons are disabled until we highlight a component in the project window by clicking on it. Manifold tries to maintain a "quiet cockpit" where controls are not enabled for use unless they can be used.

If we move the mouse cursor over an item in the project pane Manifold will tell us about that component in a tooltip. The Bay_land_eg Drawing component, for example, is a local component: it is resident in this project and is not linked into the component from some external data source.

**Step 4: Create a Map**

To create a map using this drawing we right click on a component and choose Create - Map. In the Create Map dialog that appears, all of the components in our project that can be used to create a map will appear in a list. If we right click on the Bay_land_eg Drawing component and choose Create - Map that will launch the Create Map dialog with that component already selected to participate in the map.

![Create Map dialog](image)

We can check the boxes of each component we wish to appear as a layer in the map. For now, we will leave only the Bay_land_eg Drawing component checked. We can also change the name of the map to Bay Area in the Name box and then press OK.

![Project pane](image)

A map component called Bay Area appears in the project pane. To open it in a map window, we can double-click it.
Maps are opened in a map window, which has layer tabs at the bottom of the window. The illustration above shows a map window that has been resized into a smaller size to fit into this Help file conveniently.

**Step 5: Drag and Drop Drawings into the Map**

We can add additional drawings to the map by dragging and dropping components from the project pane into the map.
Add the **Bay_hydro_eg Drawing** component by clicking on it in the project pane and dragging it into the map window and then releasing the mouse button. It will appear as a layer in the map.

Click and drag the **Bay_roads_eg Drawing** component into the map as well.

We could have created the map with all three drawings as layers by checking their boxes during the creation of the map. Had we done so the map would have been created right away with three layers. Instead, we created the map with one layer and then dragged and dropped the other drawings into the map to show that it is possible to add layers to a map by dragging and dropping components into it.

A good reason to create a map using one component and then drag and drop other components into the map window is to guarantee that the map will use a specific projection. When a map is created it takes its initial projection from the projection of one of the components used to create the map. If all of the drawings used in a map use the same projection then no matter which of them is used for the "seed" projection for the map the projection used will be the same. However, in case drawings use different projections it is wise for the new user to create maps with one component and to then drag and drop other components into those maps. This guarantees the map will use the projection of the initial component.

After we feel comfortable with projection concepts and the use of projections in drawings and maps we can, of course, create maps consisting of many components at once and still retain perfect control over which projection is used by the map.

**Step 6: Format Drawings**

Let's change the appearance of the layers in our map. We will begin by eliminating the large round dots that show the position of points.

The **hydro** and **roads** drawings came from USGS DLG maps in which every line is terminated with a point. This is important in certain types of network analyses. Manifold displays points by default as a size 3 point since otherwise they are very difficult to see as single pixel points. When using points in drawings that show, for example, the positions of cities as a point it is important to be able to see the points. In the case of roads or other drawings where points are present for network analytic reasons we don't want to see the points so we reduce their size.
Click on the points size value and change it to 1/20.

Click on the **roads** layer (we'll abbreviate names) and in the Format Toolbar change the points size value to 1/20 as well.
That's better! The above procedure reduces points to a single pixel in size on screen (and only 1/20th of a point when printed), which makes them less visible but still leaves them in the drawings. As a technique, it is something of an expedient hack.

If we don't intend to use the roads or hydro layer for analytic purposes we might choose to delete the points. This is easy. First, make the points size 3 again so you can see them and thus be impressed by what follows. Next, we setup the selection modes (see the Selection in Drawings topic) to select points only and then we use Edit - Select by Type (or CTRL-T, the keyboard abbreviation for Select by Type) to select all points in the layer. Finally, we press Delete. Good-bye points!

To change the land areas from the default gray colors we can click on the land layer and change the color of the areas to whatever color is desired.

Click on the background color well for areas in the format toolbar and choose a new color in the resultant menu of color samples.
The color selected will be applied throughout the layer for background color for areas.

Experiment with different formats for the three layers in the map. Try different foreground and background colors for areas, and different area styles. Try changing the size or color of lines in the hydro or roads layers.

For example, to change the colors of lines in the hydro layer we first click on the hydro layer tab to make it the active layer.

We then click on the foreground color for lines in the Format Toolbar and select a blue color.
Note that since there are no lines or points in the land drawing there will be no changes visible in that layer when changing line or point formats. Likewise, since there are no areas in either the hydro or roads layer there will be no changes visible in those layers as a result of changing area format.

**Step 7: Add Labels**

To add labels to the map we first create a labels layer in the map and then we add labels as desired.

Right click onto the leftmost layer tab in the map window...

...and choose Add - New Labels from the context menu.
In the **Create Labels** dialog press the **OK** button without choosing any options. This creates a new, blank labels component in the project and adds it as a layer in the map.

![Create Labels dialog]

Click on the **Insert Label** tool...
...and then click into the map at a location where a label is to appear.

Enter the text for the label, such as Angel Island and press OK. (Since label text can consist of multiple lines, pressing Enter will start a new line. Use OK to apply the label.)
Add labels as desired. They may then be formatted using the **Format Toolbar** to change style, foreground and background color, font, size and alignment.

All of the labels in a given labels layer will use the same formatting. To add labels using different styles or colors, add another labels component and create additional labels in that component. The new component may then be formatted using different format settings.

**Step 8: Save the Project**
Examples

It's easy to save a project. Choose File - Save and browse over to the folder where the project is to be saved. Enter Bay Area as the file name and push Save. The ".map" extension will be appended to the file name given and the project will be saved as Bay Area.map

**Step 9: Print the Map**

The simplest way to print a map is to open it and then use File - Print to print it. This is a quick print but has limited control over how printing occurs. A more customizable way to print is to use the map to create a print Layout and to then print the layout.

**Step 10: Experiments**

We can perform the simple steps above in different ways to experiment with the user interface. Once the project is saved, we can do whatever we like and then reload the project. Try the following:

- Use File - Create - Map to create additional maps. Try creating them with all layers at once by checking the boxes. Try using the Move Up and Move Down buttons in the Create Map dialog to specify the order of layers.
- Open more than one window for the same map by using the Open in New Window button in the project pane's toolbar. Try panning and zooming the different windows differently.
- What happens when you delete a drawing in the project pane when it is used as a layer in an opened map window?
- Try closing the project and then opening the saved version using File - Open.
- Try using copy and paste within the project pane. For now, just paste as a drawing.
- Try importing the mexico_eg sample drawing. Open the drawing's table and click and right click on various parts of the table (column heads, cells, record handles).
- Double-click open the Bay_land_eg Drawing and also double-click open the table for this drawing. Try selecting items in the drawing window. What happens in the table window?

**Important: Verifying Projections**

This example imports files from MapInfo .mid/.mif format, which does a reasonably good job of saving projection information. In this example we did not have to worry about verifying the projections used by the imported components.

The situation is very different when importing drawings or other components from formats that do not save projection information, such as AutoCAD DXF or (in many cases) ESRI "shapefiles." In that case it is possible that importing the drawing will not result in the correct projection being assigned. A good rule of thumb as to whether or not a new component is at risk of having been imported with an incorrect projection assigned is if the new component has been imported into Orthographic projection.

If there is no projection information in a file format from which the component is imported, Manifold by default will assign Orthographic projection to that component. For example, if we import an image from a non-GIS graphics format such as ordinary .jpg, .gif, .bmp or similar the image will be assigned Orthographic projection. Therefore, if a new component uses Orthographic projection Manifold is alerted to the possibility that the component has been imported from a file format that does not provide projection information.

Because it is so important that the correct projection be assigned to a new component, whenever a new component uses Orthographic projection Manifold is alerted to the possibility that the component has been imported from a file format that does not provide projection information.

**Note:** The rule of thumb used by Manifold to decide if a component has been imported from a format that does not store projection information is to simply raise the info bar whenever a new component's projection is Orthographic, the default used for imports from formats that do not provide coordinate information, or if the component has been imported in Latitude / Longitude with coordinate locations outside the expected range (+/- 90 latitude and +/- 180 longitude). Either case is a tip-off that a component has been imported from a format that does not store projections so it makes sense for Manifold to ask us to verify the projection used.
Let's see how this would have worked if our initial drawing had been imported from a geographically unaware format and so the drawing initially had been imported into **Orthographic** projection.

When first opened in a window (in this case, in a map window) Manifold will display an info bar as seen above to ask us to verify the projection of the new component.
Clicking on the information bar at the top of the window launches the Assign Projection dialog. We can use this dialog to change the projection to be used to **Latitude / Longitude** projection and then press the **OK** button.
The map window would thereafter appear with no information bar warning about the need to verify the projection of the new component. Once a component has been verified it need not be re-verified.

Verifying the projection of a new component is a routine matter in Manifold when importing from geographically-unaware formats. To avoid the constant repetition of telling users to verify the projection when an info bar like that shown above appears, this documentation will not mention this routine step except in cases where we must go beyond mere verification to specifying the correct projection.

**Notes**

This example shows a fairly typical session creating a new map. We often create a new map by importing various layers, creating a map from one of those layers and then adding other layers to that map.

There are two artificial aspects of this example. The first is that the drawings imported had no data attributes. Drawings usually do have attributes in their tables, and we will often use those attributes to help us format different parts of the drawing.

The second aspect is more subtle and perhaps a bit unfair to beginners. It is usually wise to open a new drawing in its own drawing just after import, so that the projection can be verified, before we use that component to create a map.

Suppose we import a new drawing from some legacy format, such as ESRI shapefiles, and it turns out that we didn't know a projection had to be assigned manually. If the correct projection was not assigned and we created a map from that component anyway, well, in that case we would have just created a map using an undesired projection. It's true that we would still be invited to verify the projection and we might well catch the need to assign the correct projection to the drawing and do so.

But if we already have the map created and then alter the assigned projection of the drawing used to create the map we'll end up with a drawing in one projection and a map using a different projection, such as **Orthographic**. That is not as efficient as the case where the map uses the same projection as the drawing from which it was created and it can be confusing to boot.

For that reason after importing a component it is best to pop it open to verify the projection and only after the projection has been verified should we use it to create a map. In contrast, the procedure used in this first example was overly trusting in that we created the map first and then treated the verification of the projection of...
the drawing as a mere formality. That works in the case of a reliable format like MapInfo .mid/.mif but it doesn't work all the time if devious formats like shapefiles are being used.
**Add Points with Instant Data**

Adding points to a map is a common task. We may wish to show the locations of stores, sampling equipment, fire hydrants or other items by marking their locations with points in a map. At times we will add points by importing geocoded tables. However, Manifold also makes it easy to interactively add points to a map. We can even add data at the same time we add a point to a map.

This example shows how to interactively add points to a map, using Windows *classic* style for the illustrations. We also use *Instant Data* mode and the *Object Fields* dialog to rapidly add a name for each point. We show how to move points by editing their coordinates in a table. Finally, we add labels.

**Step 1: Prepare the map to be used.**

In this example we will use the *Bay Area* map created in the My First Map example.

Open the *Bay Area.map* project file with *File - Open*. It appears as seen above when the map is opened.
Turn off the hydro layer by double clicking its layer tab and then turn off the roads layer by double clicking its layer tab. We don't need these layers for this example.

We do need an extra drawing layer in which we will add points.

To add a drawing layer, we right click on the roads layer and choose Add - New Drawing. A new drawing will be created in the project and will be added as a layer to the map just above the roads layer.

In the project pane we rename the new drawing to Stations and the drawing's table to Stations Table. We will pretend we are adding points that represent rapid response service stations for computer hardware repair.

**Step 2: Add a field and prepare to add points**

If we double click open the Stations Table we see it has no fields except the default ID field. We will add a text field called Name to the table. This will allow us to automatically add the name of each point as we enter it.
To add a field to the table we right click on a column head (like the ID column head shown above) and choose Add - Column.

In the Add Column dialog we specify "Name" for the name of the new field and choose its type to be ANSI text. Note that fields are created as integer numeric fields by default. Change the Type to ANSI text as seen above. Press OK and the field is created.

The table is still empty since there are no objects in the Stations drawing. Before adding points we will turn on Instant Data.

To do this, click on the map window so it has the focus with the Stations layer being active and choose Edit - Instant Data to turn on the check mark. When Instant Data is on, adding any objects to the drawing will pop open the Instant Data dialog that allows us to rapidly add a value to a field. Instant Data is extremely efficient when we need to add many objects with a note placed in a data field for each. See the Instant Data topic for details.

One last preparatory step: We click into the Format toolbar and choose bright green for the background color for points and 4 for their size. This will make the newly created points clearly visible.

**Step 3: Add points using Instant Data**

Click on the Insert Point tool to begin adding points.
Position the **Insert Point** cursor where the new point is to appear and click.

When we click to insert the point the **Instant Data** setting will cause the **Object Fields** dialog to automatically pop open. It will be pre-loaded with the **Name** field ready for editing since that is the only editable field in our table.
We can add the text value *Marin* and click **OK** (or simply press **Enter**).

A point appears in the **Stations** drawing in the map where we clicked.

If we look at the **Stations Table** we can see a record has been added for the point with the text value **Marin** in the **Name** field.
We can position the **Insert Point** cursor once more in the map and click.

When **Instant Data** is on, every time we insert a point the **Object Fields** dialog will launch to allow us to add a value. The dialog will launch with the last-edited field ready for editing with the last-used value already entered.
For this point we will use the text value **San Francisco** in the **Name** field and then press **OK** (or press **Enter**).

When we press **OK** another point appears in the **Stations** layer.

In the **Stations Table** another record appears for the new point with the text value **San Francisco** in the name field.
We can continue to click into the map in this fashion to add more points. With each point added we can specify the value for the Name field for that point in the Instant Data dialog. This is very fast.

For each point the Stations Table will be updated with the values we entered.

**Step 4: Adjust positions using intrinsic fields**

After adding a point to a drawing we may wish to adjust the latitude and longitude coordinates of the point to move it to a precise position. Suppose, for example, we've visited Intel in Santa Clara and have noted the exact coordinates of our service station location with a GPS. We would like to move the point we added for Intel to the exact latitude and longitude measured with the GPS.

We can accomplish this by showing intrinsic fields in the table and changing the values of those fields. Intrinsic columns are not shown by default in tables. We can use the View - Columns command to show intrinsic fields. See the Intrinsic Fields in Tables topic for details on intrinsic fields.
Turn on intrinsic fields by clicking open the Stations Table table and then choosing View - Columns. In the Columns dialog check the boxes next to the Longitude (I) and Latitude (I) intrinsic fields and press OK. The intrinsic fields will appear in the table. To change the Longitude (I) position for Intel we simply double click into the cell, specify the value desired and press Enter.

The intrinsic fields will appear in the table. To change the Latitude (I) value we likewise double click into the cell and edit the value as desired. The point will move to the new location specified by the intrinsic fields. [Depending on refresh settings, the points may not actually move in the drawing unless the drawing window is closed and then opened again.] Note: these values are made up values for the sake of this example. Intel is not located exactly at the position shown.

**Step 5: Add labels to the map**

If we like, we can use the Name field we’ve added to create labels for the new points. To do this, right click on the Stations drawing component in the project pane and choose Create - Labels in the context menu.
The Create Labels dialog will appear. The dialog knows we right clicked on the Stations drawing so it will highlight that drawing in the upper, Parent, pane assuming we want to create labels using the fields in that drawing.

We double click on the Name field in the Columns pane to add it as part of the label text in the lower pane. The other fields listed are intrinsic fields that we are not interested in using. Press OK to finish. See the Creating Labels from Fields topic for details on creating labels using this dialog.

The result is a new labels component called Labels that appears in the project pane underneath the Stations drawing. To show the labels in the map we drag and drop the Labels labels component from the project pane into the map window.
We can specify the alignment of the labels using the alignment controls in the format toolbar for labels. In the illustration above we’ve specified that the labels should appear below and to the left of their tie points. See the Aligning Labels topic for details.

**Latitude and Longitude Notation in Editing**

Manifold tables show latitude and longitude intrinsic fields using decimal degrees notation by default. When editing intrinsic fields, Manifold allows entry of values in either decimal or in degrees, minutes, seconds notation using almost any separator between the degrees, minutes and seconds values.

For example, if we want to enter a value of -122.55125 degrees we can double click into the Longitude (I) box and enter any of the following:

- -122.55125
- -122d33m4.5s
- -122 33 4.5
- -122^33'4.5"
- 122.55125W
- W122d33m4.5s

Manifold will interpret any non-numeric character in between the numbers other than a decimal point as a separator between degrees, minutes and seconds values. The letters W and S either before or after the other characters are commands to make the value a negative (west) longitude or negative (south) latitude.

Note that case is significant in NESW notation, so that 22d33m4.5s would be a North (positive) latitude and 22d33m4.5S or 22d33m4.5sS would both be South (negative) latitudes.

Whatever notation style is used to enter the new value, it will be displayed using the column format specified for that column.
Examples

Create a Projected US Map

Projections are used to give geographic maps a more natural appearance. They also allow accurate measurement in many ways not otherwise possible. We will often acquire GIS data in unprojected ("Latitude / Longitude Projection") form. This example shows how to present such data in projected form.

Important: If you have installed 64-bit Manifold, do this example in 32-bit mode by launching Manifold System using the Manifold System (32-bit) shortcut. See the note on 64-bit Manifold at the end of this topic.

We begin with an unprojected drawing of the United States. To show this in projected form we have two choices:

- Project the drawing into the desired projection and then use it to create a map. The map will automatically use the projection used by the drawing originally used to create the map. When creating maps from large drawings or images this results in faster display.
- Leave the drawing in unprojected form and then use it to create a map. We can then change the Edit - Assign Projection setting in the map to use whatever projection is required. This method is flexible because it leaves the drawing in the original state in which it was imported. However, with larger drawings or images it will result in slower display speed for maps because the native data within each drawing or image in the map must be re-projected on the fly to display in the desired map projection.

In the first part of this example we import a drawing of the United States and then project it into Lambert Conformal Conic projection. We then create a map from the projected drawing. In the second part of this example we import the drawing and leave it in unprojected Latitude / Longitude projection. We use it to create a map and then we change the map's projection.

This example uses a file in .mfd/.mdb format. In this format, there are two files, one ending in .mfd and one ending in .mdb, both with the same name, that make up the GIS drawing. When copying from the Manifold CD to your hard disk, make sure to copy both files. For example, when copying the US_Main drawing from the Manifold CD to your hard disk (if you choose to do so), don’t forget to copy both US_Main.mfd and US_Main.mdb together to the same hard disk folder.

First Method: Re-project the drawing and create a map.

Step 1: Import and open a drawing

We will use the US_Main.mfd example drawing. Launch Manifold and choose File - Import - Drawing with the Files of type box set to MFD Files.

| File name: | US_Main.mfd | Open |
| Files of type: | MFD Files (*.mfd) | Cancel |

Browse over to where the US_Main.mfd file is kept on your system and click on it to load the File name box in the Import dialog as seen above. Press OK to import the file. Press OK again in the Import MFD File dialog (not illustrated) to import the file with all fields by default.

The result in the project pane is a new drawing and its associated table. Double click the drawing name to open it in a drawing window. (A tool tip pops up to let us know this drawing is a local drawing, that is, it is stored entirely within the project file as opposed to being linked in from some remote data source.)
The drawing window shows us the **US_Main Drawing** as seen in the "unprojected" *Latitude / Longitude* projection.

**Step 2: Re-project the drawing**

Choose Edit - Assign Projection to confirm that the projection assigned to the drawing on import is correct. The command will launch the **Projection** dialog to **confirm** the projection assigned. Click OK. Now, choose Edit - Change Projection to project the drawing to another projection. The command will launch the **Projection** dialog to **change** the projection used by this drawing.

**Note:** We use Assign Projection to verify the projection before Change Projection because Manifold wants us to verify the projection of a drawing is correct before it will allow us to change the projection. Trying to re-project a drawing where the original projection was not correctly assigned will cause chaos, so Manifold insists we check that initial assignment of projection is accurate.

The **Latitude / Longitude** projection is highlighted in the projections tree to show us that is the projection currently in use for this drawing. We click on the **Conic** hierarchy to expand it.
In the expanded Conic projections hierarchy we choose Lambert Conformal Conic. This projection is well suited for maps of the lower 48 US states. See the Projections topic for discussion and links to other topics that provide advice on choosing projections.

Clicking on Lambert Conformal Conic loads the parameters pane with the parameters (such as the Center Latitude and Center Longitude) that may be set for this projection. By default the projection parameters are all set to 0.00. To provide sensible parameters for this drawing we press the Suggest button.
The Suggest button loads the projection parameters with suggested values to use. Note that latitude 37 and longitude -96 is about the center of the United States. See the Lambert Conformal Conic topic for information on suggested settings for these parameters. We press OK to re-project this drawing.

The result is that the drawing is re-projected into Lambert Conformal Conic projection using the parameters specified.

**Step 3: Create a map from the drawing**

If this single drawing is all we will use, there is no need to create a map. We can perform formatting and print directly from the drawing window if so desired. However, if we intend to have a map with other layers we can create a map from the drawing. We can then add other layers to the map.
To create a map we click on the **Create** button in the project pane.

In the pull-down menu that appears we choose **Map** to launch the **Create Map** dialog.

The **Create Map** dialog lists only one component, the **US_Main Drawing**, because it is the only component in our project so far. If we had other components in the project these would be listed as well. We change the name to **US Map**. By default the checkbox is checked for this component so all we need do is press **OK** to create the map.

A new map is created in the project. To open it we double click on the map name in the project.
The result is a map that shows our drawing. Because the map was created using a drawing that was in Lambert Conformal Conic projection, the map also uses this projection for its view.

**Second Method: Create a map from the drawing and change the map's projection**

In the method used above we imported a drawing, re-projected the drawing and then created a map. We could achieve the same visual effect in the map by importing the drawing, creating a map and then changing the projection used to show the view in the map.

The distinction is that in the first case the drawing is modified to a new projection so that when the map shows this drawing in that same projection both the drawing and the map are using the same projection. In the second case, the drawing is not modified: it retains the original projection. The map, however, will dynamically re-project the data within the drawing to show it in whatever projection view we choose.

The first step using the second method is to import the drawing. However, since we will not re-project the drawing there is no need to open it.

**Step 1: Import a drawing**

We will again use the US_Main.mfd example drawing. Launch Manifold and choose File - Import - Drawing with the Files of type box set to MFD Files.

Browse over to where the US_Main.mfd file is kept on your system and click on it to load the File name box in the Import dialog as seen above. Press OK to import the file. Press OK again in the Import MFD File dialog (not illustrated) to import the file with all fields by default. The result in the project pane is a new drawing and its associated table.

**Step 2: Create a map from the drawing**

Even if this single drawing is all we will use in our project in this case we will need to create a map to see the drawing in the desired projection.
To create a map we click on the Create button in the project pane.

In the pull-down menu that appears we choose Map to launch the Create Map dialog.

As before, the Create Map dialog lists only one component, the US_Main Drawing, because it is the only component in our project so far. We change the name to US Map and press OK to create the map.
A new map is created in the project. To open it we double click on the map name in the project.

The result is a map that shows our drawing. Because the map was created using a drawing that was in Latitude / Longitude projection, the map also uses this projection for its view.

**Step 3: Change projection used by the map**

Changing the projection used by a map to show its contents is very similar to re-projecting a component except that the **Edit - Assign Projection** dialog is used instead of the **Change Projection** dialog. The **Assign Projection** dialog is used because altering the projection used by a map does not re-compute the coordinate data inside the components used in the map: it simply changes the projection used by the map to view the layers in the map. To change the projection used by this map we choose **Edit - Assign Projection**.

The Latitude / Longitude projection is highlighted in the projections tree to show us that is the projection currently in use for this map. We click on the **Conic** hierarchy to expand it.
In the expanded **Conic** projections hierarchy we choose Lambert Conformal Conic.

To provide sensible parameters for this map we press the **Suggest** button.
The **Suggest** button loads the projection parameters with suggested values to use. It will suggest the same values as seen in the first method since the drawing in use in the map is the same. Press **OK** to change the projection view used by the map.

The result is that the map now shows its contents in the **Lambert Conformal Conic** projection using the parameters specified. The new projection is computed on the fly without changing the contents of the **US_Main Drawing** component.
In fact, if we double-click open the **US_Main Drawing** component we can see that it is still in **Latitude / Longitude** projection.

Leaving the **US_Main Drawing** in its original **Latitude / Longitude** projection is not a bad idea if this drawing will participate in other maps in our project that will use different projections. It takes computational overhead to re-project a drawing on the fly to display within a map that uses a different projection, but if the data set is small (that is, few coordinates defining the objects in the map and few objects in the map), then the overhead is not too burdensome. If we have large data sets (drawings with many, very detailed objects) then it pays to re-project the drawing or the map so that both use the same projection.

This example drawing is a relatively small data set so we can easily use it within different maps that use different projections and it will be re-projected on the fly for display.

**Using US_Main in a world map**

Suppose for example we wish to use **US_Main** as a layer in a world map. Using a procedure analogous to that shown in the second method above, we will create a world map using the **World_eg.mfd** example file. To do so we will:

- Import **World_eg.mfd**.
- Use **Edit - Assign Projection** to verify the projection used by the **World_eg** drawing.
- Create a map using the **World_eg Drawing** component as the only layer and name it **World**.
- Open the **World** map.
- Use **Edit - Assign Projection** to change the projection used by the **World** map into the Robinson projection.
At the end of the above sequence the World map will appear as seen above. Note that it shows its contents using the Robinson projection even though the World_eg drawing is in Latitude / Longitude form.

To add the US_Main Drawing to the World map we click on it in the project pane and drag and drop it the highlighted drawing from the project pane into the opened World map window.
The result is that the **US_Main Drawing** appears as a layer in the **World** map. In the illustration above we have taken a moment to click on the **Background Color** well for areas in the **US_Main Drawing** and have changed it to bright yellow. This makes the **US_Main Drawing** layer more obvious in the map.

We can have multiple windows open at once that show the **US_Main Drawing** component in different projections. In the upper left of the screenshot above we see the component open in a drawing window where it is seen in its native **Latitude / Longitude** projection. Drawing windows always show their drawing in the native projection of that drawing.

In the lower left we see the **US Map** map window that has been instructed to show its contents using **Lambert Conformal Conic** projection. At right we see the **World** map window that has been instructed to show its contents in the **Robinson** projection.
Note that changing the format of a drawing changes the appearance of that drawing in all cases. When we changed the background color of areas to yellow for **US_Main Drawing** the color change was updated in all three windows.

**Note**

The screen shot above shows an actual Manifold session open with three windows. The windows have been resized to be very small so that the screen shot can be made small enough to fit into this document. In normal usage of course the windows would be larger. Manifold users often will have large screen monitors with high resolution so they can keep several conveniently large windows open at the same time.

An interesting note for Manifold users who are unfamiliar with the world of legacy GIS applications is that some old-fashioned GIS packages can’t show more than one window open at the same time. Surprisingly, even though they may cost thousands of dollars they not only cannot show the same drawing re-projected on the fly in multiple windows, they can’t even show more than one window open at a time. Amazing!

### Important Note when Using 64-bit Manifold Editions

Due to a lack of required Microsoft facilities in 64-bit Windows systems, Manifold in 64-bit mode cannot export, import, export or link to DB, HTML, MDB, XLS or WKx format files. This includes no access to the MDB parts of Manifold MFD and MapInfo TAB imports. The workaround for importing or exporting such files is to launch Manifold in 32-bit mode by using the Manifold System (32-bit) shortcut, perform the export from or import into a .map project file and then re-launch Manifold in 64-bit mode using the Manifold System (64-bit) shortcut. Linking is more complex: the data must be in some format usable in 64-bit mode within 64-bit Windows systems, such as a SQL Server database. Alternatively, the data can be kept within a Manifold .map project file and linked using the Manifold ODBC driver.

Examples

Using Layers

Layers in maps are components such as drawings, images, surfaces or labels components. We can use layers to organize our data and to present it through good formatting. This example shows how to move objects between drawing layers and how to format different layers.

**Important:** If you have installed 64-bit Manifold, do this example in 32-bit mode by launching Manifold System using the Manifold System (32-bit) shortcut. See the note on 64-bit Manifold at the end of this topic.

In this example we begin with a map with one layer, the US_Main Drawing projected map created in the Create a Projected US Map example. We then select groups of states and move them into new layers to create a map with three layers.

Recall that layers in a map can be images, drawings, surfaces or labels components. Every time we add a drawing layer to a map we create a new blank drawing in the project pane. When a map consists of drawings only, each layer in the map is a drawing.

**Step 1: Copy and paste western states to a new drawing layer**

Import US_Main.mfd and project the drawing into Lambert Conformal Conic projection. Create a map using this drawing. Use the procedures in the Create a Projected US Map example.

We see the map in the illustration above. The drawing layer has been renamed US_Main for brevity.

Set up Add to Selection selection mode, Select Areas selection objects and the Select Touch selection tool as seen above. Each area we touch with the mouse will be added to the selection.
Touch eleven western states as seen above.

Cut the states out of the US_Main layer using CTRL-X or Edit - Cut.

Right click onto the US_Main layer tab and choose Add - Drawing to create a new drawing layer. Call this drawing West.
Paste into this layer using CTRL-V or Edit - Paste.

The Paste Objects dialog appears asking how to paste the fields associated with these objects. The US_Main drawing has several fields for each state. When the West drawing layer was created it had no columns in the drawing's table for that layer. If we use the default settings in this dialog it will create new columns in the table for the West drawing layer. Press OK to use the defaults.

The eleven western states appear in the West layer. Newly pasted objects are selected.

We can deselect them by pressing the Select None button. They will then appear in the default gray color format.

To change the color of the western states, we click on the background color well for areas in the Format toolbar.
Choose a light yellow color in the color menu that appears.

Changing the color to light yellow in the toolbar will change the color of the objects.

The western states areas will now appear using an areas background color of light yellow.

**Step 2: Copy and paste central states to a new drawing layer**

Copying states from a central region to a new layer uses the same procedure as in the preceding step.
Click on the **US_Main** layer to make it the active layer. Click on the states shown to select them (the selection tool should still be set to **Select Touch**). If we do not first click on the **US_Main** layer to make it the active layer we will not be able to select these states because they would not be in the active layer. Selection and Clipboard (Cut, Copy, etc) operations in maps work on the active layer by default. To extend the action of these operations to all visible layers, press the **ALT** key.

Press **CTRL-X** or use **Edit - Cut** to cut the states out of the map.
Right click onto the US_Main layer tab and choose Add - Drawing to create a new drawing layer. The new layer tab will be created to the left of whatever tab was right-clicked. Call this new drawing Central.

A brief digression: We can alter the appearance of the map window by turning the background off and on.

If we open up the Layers pane with a SHIFT-ALT-L or with a View - Panes - Layers menu command we can uncheck the Background box to turn off the background.

Without the background, the default checkerboard background pattern shows through. Note that we can also turn layers off and on very quickly by checking and unchecking their boxes in the Layers pane.

Check the Background box again to restore the white background.
Click on the **Central** layer tab to make it the active layer. Press **CTRL-V** or **Edit - Paste** to paste the objects in the clipboard into the layer. Once again the **Paste Objects** dialog will be raised (not illustrated). Press **OK** to accept the defaults in the dialog and to paste into the layer. The central states will appear in red selection color. Press **Select None** to deselect them.

To format areas in this layer a color different than gray, click on the background color well for areas in the **Format** toolbar.

Choose a light green color from the color menu that appears.

The color well in the toolbar will show the new color selected.
All areas in the **Central** layer will be colored using the new format.

**Step 3: Rename US_Main layer**

To provide a non-default color for the remaining layer, we click on the **US_Main** layer to make it the active layer and then click on the background color for areas in the format toolbar to change the color.

We can change the color to a light blue. To complete our map dividing the US into three regions, in the project pane we rename the **US_Main** drawing to **East**.

The layer tab for this drawing in the map will also automatically be renamed.

**Step 4: Moving objects between layers**

We've completed the map we set out to create. If desired, we can make changes in it by moving objects between the layers created. For example, suppose we decide that Michigan should be assigned to the **East** layer instead of the **Central** layer.
Click on the **Central** layer tab to make it the active layer and then click on Michigan to select the state.

Press **CTRL-X** or **Edit - Cut** to cut the state out of the **Central** layer. Click on the **East** layer tab to make it the active layer.

Press **CTRL-V** or **Edit - Paste** to paste Michigan into the **East** layer. Note that the **Paste Objects** dialog is not raised because the field structure from the origin layer matches the destination layer.
If we press Select None to deselect Michigan we see that it appears in the light blue format color used for areas in the East layer.

**Important Note when Using 64-bit Manifold Editions**

Due to a lack of required Microsoft facilities in 64-bit Windows systems, Manifold in 64-bit mode cannot export, import, export or link to DB, HTML, MDB, XLS or WKx format files. This includes no access to the MDB parts of Manifold MFD and MapInfo TAB imports. The workaround for importing or exporting such files is to launch Manifold in 32-bit mode by using the Manifold System (32-bit) shortcut, perform the export from or import into a .map project file and then re-launch Manifold in 64-bit mode using the Manifold System (64-bit) shortcut.

Linking is more complex: the data must be in some format usable in 64-bit mode within 64-bit Windows systems, such as a SQL Server database. Alternatively, the data can be kept within a Manifold .map project file and linked using the Manifold ODBC driver.
**Color a Drawing**

At times we would like to color a drawing of areas so that no two adjacent areas have the same color. To do so, we use the Color dialog to automatically color areas.

**Important:** If you have installed 64-bit Manifold, do this example in 32-bit mode by launching Manifold System using the **Manifold System (32-bit)** shortcut. See the note on 64-bit Manifold at the end of this topic.

**Step 1: Import and open a drawing**

We've imported a drawing of US states (the **US_Main.mfd** sample drawing) and have projected it into Lambert Conformal Conic projection. Seen in default colors, all of the states are drawn using default light gray background color. To import and project the drawing used the procedures described in the previous Example topic, Create a Projected US Map.

We've imported a drawing of US states (the **US_Main.mfd** sample drawing) and have projected it into Lambert Conformal Conic projection. Seen in default colors, all of the states are drawn using default light gray background color. To import and project the drawing used the procedures described in the previous Example topic, Create a Projected US Map.

If we open the table for the drawing we can see it has five fields.

**Step 2: Launch the Color Dialog**

Click on the opened drawing so it has the focus and choose **Drawing - Color** from the menu.

![Color dialog](image)
We use the default settings in the **Color** dialog. See the Color topic for details on operating this dialog.

The nearly instantaneous result is a drawing that's been colored so that no two adjacent states have the same color. Only four colors have been used. The drawing has been colored by creating a thematic format for the area colors.

The **Color** dialog creates a thematic format for both the **background** color as well as the **foreground** color as can be seen by the format toolbar colors for areas seen above. The foreground color theme is a darker version of the background color with the expectation that an area style using foreground color for apparent boundary is being used.

</tbody>
</table>

If we open the drawing’s table we can see that a new field called **Color** has been added to the table. This field contains the value 1, 2, 3 or 4. The field is then used in the thematic format to color the drawing.

**Step 3: Adjust Colors if Desired**

It’s easy to change the color scheme after applying the color dialog. Simply click on the background color well for areas and choose **theme** and then apply one of the preset color schemes. The color applied by the color dialog is simply a thematic format using the **Color** field with a **Unique Values** method. If we choose a different color preset we can alter the colors at will.
First we click into the foreground color well and change it to dark gray. Dark gray boundary lines will look better with whatever new color scheme we choose.

We click on the background color well for areas to change the thematic format for areas.

In the pull down color choice menu we choose Theme to launch the thematic formatting dialog.

In the thematic formatting dialog we choose Color for the field and Unique Values for the method and Yellows for the palette.

We press Apply to apply the color range and then press OK.
The result is a thematic format using a range of yellow colors. Instead of using a preset like Yellows, of course, we could have clicked into the color wells in the thematic formatting dialog and set whatever colors we liked.

**Extra Credit: Adjust Area Styles**

We can use thematic formatting with the **Color** field to adjust area styles instead of (or in addition to) color. Click into the foreground color and background color wells for areas in the format toolbar to change them to dark gray and very light gray respectively.

This eliminates the thematic format and results in the map seen above. However, the "coloring" values in the **Color** field are still there in the drawing's table.

We can use those values to do a thematic format that changes area style.
To do so, click on the styles well for areas and choose Theme.

In the Format dialog choose Color as the controlling field and Unique Values as the method. Click into the various styles wells for the values 1 through 4 and change them to a desired area style.

The result is a drawing where no two adjacent areas have the same area styles.

Important Note when Using 64-bit Manifold Editions

Due to a lack of required Microsoft facilities in 64-bit Windows systems, Manifold in 64-bit mode cannot export, import, export or link to DB, HTML, MDB, XLS or WKX format files. This includes no access to the MDB parts of Manifold MFD and MapInfo TAB imports. The workaround for importing or exporting such files is to launch Manifold in 32-bit mode by using the Manifold System (32-bit) shortcut, perform the export from or import into a .map project file and then re-launch Manifold in 64-bit mode using the Manifold System (64-bit) shortcut.

Linking is more complex: the data must be in some format usable in 64-bit mode within 64-bit Windows systems, such as a SQL Server database. Alternatively, the data can be kept within a Manifold .map project file and linked using the Manifold ODBC driver.

See the Thematic Formatting Example topic for an example of thematic formatting.
Examples

Import a Drawing from the Geocoding Database

Drawings may be imported from the Manifold Geocoding Database that is provided for free download from the manifold.net website. The geocoding database provides information on streets and addresses in the United States that is organized on a county basis, but it also includes supplementary cartographic information. Although the principal use of the geocoding database is to provide address range data for street address geocoding the data may also be used to create drawings that show streets and hydrological features within the United States.

Like the rest of Manifold's street address geocoding capability, import from the geocoding database becomes operational only when the optional Manifold Geocoding Tools package is installed. If you do not have the optional Geocoding Tools package, you will not be able to take advantage of the import capability described in this topic.

See the Import Drawing - Geocoding Database topic and the Geocoding Data Sources topic for additional information, including instructions for installing the Manifold Geocoding Database onto your hard disk. If you have not installed the Manifold Geocoding Database, you will not be able to follow the procedure described in this topic.

This example shows how to import a drawing for Placer County, California. We then separate hydrological features into a second drawing and combine the two drawings into a map. Even those users outside the United States who are not interested in drawings of counties in the US should still read this example for an illustration of the technique of using a data attribute field to select objects within a drawing and move them to a separate drawing.

Step 1: Import Drawing

Choose File - Import - Drawing to launch the Import Drawing dialog.

In the Import Drawing dialog choose Geocoding Database Files in the Files of type box and then browse over to the folder in which the Manifold Geocoding Database files have been installed. Double click on the states.dat file.

Note: to use this procedure you must know where the geocoding database has been installed and be able to find the states.dat file. By default, the geocoding database is installed in the C:\Program Files\Manifold
System\GCDB folder. If you or someone else installed the geocoding database in a different location, such as on a network share, make note of where it was installed and browse to that folder.

In the resulting Import Geocoding Database dialog specify Placer, CA as the county name. Note that even though the technical name of the county may be "Placer County" we don’t use the "County" appendage.

All fields are checked for import by default and for the sake of this example we don’t bother un-checking any fields. Since most people will use this particular import capability to create background maps of streets or other features in applications where technical details of address ranges and other fields are not required, in many cases users will import only the Street and CFCC fields. But for now we just import everything and click OK.

The result is that a new drawing appears in the project pane.
If we open that drawing we see that it shows features in Placer county and has already been thematically formatted by default.
Clicking open the thematic format for foreground color of lines, we can see that the thematic format uses the CFCC field to thematically format colors based upon the various feature codes in the CFCC field. Even if we were unfamiliar with the standard values used in by the Census Bureau to encode different features in the CFCC field, we could easily guess that feature codes beginning with an H represent hydrology, that is, water, features.

See the Import Drawing - Geocoding Database topic for a list of CFCC codes.

**Step 2: Select Hydrology Features**

As imported, the drawing contains all features available within the geocoding database. Features have been thematically formatted to set them apart. That is a typical way to use a drawing that contains many features, especially if it is just intended as a background for other layers.

At times it may be more convenient to separate out the contents of a drawing into different drawings, for example, to separate out hydrology features into a separate drawing. Or, perhaps we would like to simplify a drawing by removing features that are not of interest. Doing so within Manifold is easy: we select the desired features and Cut them out of a drawing. We can then Paste them into a new drawing or simply discard them. Let's use hydrology features as an example.

To select all hydrology features we use the selection toolbar to select all CFCC features that contain the letter H.

Since CFCC codes only contain one letter, the initial letter, using a relatively simple selection method such as "containing H" will select all records for hydrology features since all of the CFCC codes for such features begin with H, as we can see by reviewing the table of CFCC codes given in the Import Drawing - Geocoding Database topic.
When we press the **Select** button in the toolbar all of the hydrology lines (those lines with an *H* in their CFCC field) are selected.

**Step 3: Cut Hydrology Features and Paste as New Drawing**

To **Cut** the lines out of the **Placer** drawing we click on the drawing to make sure it has the focus and then we do either an **Edit - Cut** or simply a **CTRL-X**, the standard Windows keyboard shortcut for Cut. Doing a Cut as opposed to a **Delete** will not only delete the lines from the drawing but will also **Copy** them to the Windows clipboard.
The lines disappear from the Placer drawing. To put them into another drawing, we can right click onto the project pane and choose Paste to paste them from the Windows clipboard into a new drawing. We could also use, if desired, the Windows keyboard shortcut for Paste by doing a CTRL-V.

The result is that a new drawing, called Placer Drawing 2 appears in the project pane.
If we open that new drawing we see it contains the hydrology lines that were cut out of the original Placer Drawing.

**Step 4: Create a Map**

It’s often the case that we would like to keep different classes of lines, such as streets or hydrology lines, within different drawings and then show those different drawings together as layers in a map. Creating a map is easy.

We begin by renaming Placer Drawing 2 into a more descriptive name. We’ll call it Placer Hydro. Next, we right-click on the Placer Hydro component in the project pane and choose Create - Map.

In the Create - Map dialog we check the boxes for both Placer Drawing and Placer Hydro and we press OK.
When we open the resulting map we see it contains both drawings as layers.

**Notes**

Placer County gets its name from the nomenclature of the California Gold Rush in the late 1840’s. A **placer** is a deposit of gold-rich sand or gravel, as are found in the Western foothills of the Sierra Nevada mountain range on the border between California and Nevada in the United States.

Placers were formed tens or hundreds of thousands of years ago when streams eroded the mountains and carried bits of gold worn from the hard rock of the Sierras downstream. Where streams took a bend, the rushing water slowed down and the reduced velocity of flow allowed the very heavy gold to settle at the bend, often at the same location where a gravel bank or deposit of sand would also build up.

Over time the streams dried up and their beds and banks were covered up by soil and scrubland and forests, but the beds where gold accumulated remained. A lucky or skillful miner might find such a placer and discover extremely rich concentrations of gold. Placer County stretches from the California central valley Eastward up into the foothills and mountains of the Sierra Nevada. It includes territory in which some of the richest gold strikes in history were made.

Although made famous by the California Gold Rush, placer deposits occur throughout the world, wherever erosion of gold-bearing rock and the flow of ancient streams have accumulated a mix of gold and sand or gravel.

Import Drawing - Geocoding Database
Fun with Google Earth

If we have drawings or images we would like to publish in Google Earth we can export them to KML or KMZ files. Double-clicking a KML file will automatically open it in Google Earth (assuming Google Earth has been installed on the computer system), so using KML is a great way of sending GIS data to our friends when the intent is mainly visual.

We can send a KML file as an attachment to email or provide it on a web site. Our friends can click it open and then see what we want them to see in Google Earth. Although Google Earth has some limitations, such as an inability to work with more than two simple data fields, that make it unsuited for sophisticated GIS data, KML files allow us to use Google Earth as a free “GIS viewer” for simple data.

A KMZ file is simply a “zipped” KML file. KMZ is smaller because it is compressed but it is not immediately human-readable unless it is unzipped. KMZ is preferred for exporting images to Google Earth because the image will be embedded within the KMZ file.

Projections and KML Format

Google KML and KMZ formats support Latitude / Longitude projection using the WGS 84 Auto datum only. Drawings to be exported to KML or KMZ can be in any projection and will be re-projected on the fly into Latitude / Longitude during export; however, to avoid a potentially slow re-projection process it is wise to explicitly re-project drawings into Latitude / Longitude using the WGS 84 Auto datum before export. This not only avoids a slow export, it also provides an opportunity to catch errors before export if the re-projection results in a strange display as might happen if the initial projection was not correctly assigned, say, after importing projected data from some format that does not store projection information.

Unlike drawings, images must be in Latitude / Longitude projection to be exported to KML or KMZ.

Exporting Drawings with Points to KML

It’s easy to export drawings with points to KML.

Consider the table showing geocoded addresses of sushi restaurants near Menlo Park that was seen in the Linked Drawings from Geocoded Tables topic as well in the various street address geocoding topics.

In the Manifold project pane, Copy the table and then Paste As a drawing. The default dialog for pasting will know the table being pasted is Latitude / Longitude data and will pre-load column choices for us.
We rename the drawing to *Sushi Spots* and open it as seen above. We’ve formatted the points to a brighter color and have changed the point style a bit.

With the drawing open we choose *File - Export - Drawing* and then use *Sushi Spots.kml* as the file name. In the *Save as type* box we choose *KML / KMZ Files* and press *Save*. In the *Export KML File* dialog that pops up we choose the *Name* field and the *Address* field as the description. Press *OK*. That’s all!

We can now send the resulting *Sushi Spots.kml* to our friends, post it on web sites or whatever. Double-clicking the *Sushi Spots.kml* open launches Google Earth and causes it to zoom down from space to the Menlo Park / Palo Alto area where we can see our locations as above.
With only two fields to work with, Google Earth does not give us much in the way of data manipulation or display capability, but if we use it wisely we can still get useful effects. For example, using the name of the restaurant for the **Name** field works just fine as a label, and using the **Address** field (just the street address part of it) works well as a description in the auxiliary Google Earth information pane.

The above technique is simple and fast, especially if we remember to use drawings that are in **Latitude / Longitude**. The technique is nearly impossible to get wrong.

This example uses points that came out of a table, but we could have used any drawing of points. For example, we could have been using a drawing that showed fire hydrant locations collected by the public works staff for our city, or we could be doing surveys of parks and noting individual trees by GPS, citing abandoned mine locations, navigation buoys, dealer locations or anything else of interest.

**Exporting Drawings with Lines to KML**

Let's dial up the fun some more by exporting a drawing that contains lines to Google Earth. We will use the drawing of Placer County, California, created in the previous Import a Drawing from the Geocoding Database example.

The drawing appears above using new thematic formatting. Because Google Earth has a dark photographic image as background it is best to use very bright colors for lines so they display well in Google Earth. We created the above formatting by clicking on the format toolbar color well for line foreground color.
We then changed the thematic format used by default when importing from the geocoding database to brighter colors, as seen above.

Exporting to KML is trivial. With the drawing open we choose File - Export - Drawing, in the Save as type box we choose KML / KMZ Files, provide a suitable file name such as Placer County.kml (don't forget the .kml extension) and press Save.
Examples

Double-click open the .kml file and Google Earth launches and displays the contents on a background of local imagery, as seen above.

Zooming in a bit we see that even in distant areas and despite the intrinsic imprecision of Google Earth the correlation between government GIS data as used in the geocoding database and Google Earth is excellent. Google Earth adds some roads and roads labels by default, which is often useful and improves the display.

We can do a lot of work in Google Earth just using lines and points. Lines are especially popular to show tracks downloaded from GPS devices (see the Working with GPS Receivers topic) or for displaying any drawings of lines, as are created so often in ordinary GIS work. The next time you take your bike off-road for a cruise through the Sierra Nevada, leave a GPS device running on the bike to build a track. When you get home, download the track into a Manifold drawing, export it to KML and send the KML file to your friends so they can see where you’ve been on Google Earth.

Exporting Drawings with Areas to KML

Google Earth can also show areas, and Manifold can export areas to KML. The procedure is the same as exporting points or lines. Drawings exported to KML may include a mix of points, lines and areas. Points and lines are exported to KML using solid, opaque color, while areas are exported using partial transparency.
Consider a drawing showing selected congressional districts from the 109th Congress. The districts have been selected as exceptionally Gerrymandered based on their perimeter to area ratio. Districts are shown as areas, colored to be visually distinct, with black color for area border lines.

"Gerrymandering" is a method of rigging elections used in the United States by both parties. The practice nullifies the votes of the targeted minority party by drawing congressional districts so that the voters are grouped into voting districts that the minority party cannot win. It is a highly anti-democratic and corrupt practice that, of course, is enthusiastically embraced by incumbent politicians.

The drawing above is shown in Lambert Conformal Conic projection. It has been zoomed in to show only a few of the highly Gerrymandered districts.

The drawing of congressional districts was taken from the National Atlas of the United States. The table includes data fields for each district. Some districts consist of more than one area object (typically islands) so there is more than one entry in the drawing's table for each district. If we were creating this drawing for "real life" use instead of as an export example, we probably would have taken a moment to use Dissolve to collapse all of the separate area objects associated with each district into a single area object that is "branched," that is, it looks like different objects but in fact all the islands and other visually separate pieces are part of the same area object. We could use the NAME field to do a dissolve.
We export the drawing to KML by choosing File - Export - Drawing as in the previous examples, choosing a filename ending in .kml to create a KML file. In the Export KML File dialog we choose the NAME field for Name and the URL field for the Description. Press OK.

When we open the KML in Google Earth we see the areas have been rendered with partial transparency. The color of the area border line is black just as was the formatting in the drawing.

**Note:** Manifold can export from maps to KML, in which case the drawing objects sent out to the KML file will be rendered with whatever layer opacity was used for that layer in the map; however, areas are always rendered using partial opacity with that partial opacity being modified by whatever layer opacity setting has been used in a map. That is, areas can be made even more transparent but can not be made fully opaque.
If we zoom into the region in the lower right we can see an example of anti-democratic Gerrymandering, the contorted blue and purple districts. The purple district is the voting area for a single Congressional representative. It is one contiguous area and not several disconnected areas. For example, it is attached by fine corridors passing through enemy territory along the lower left portion of the district. The blue district looks like two or three disconnected regions, but each is indeed connected to the others by thin corridors. This sort of thing passes for democracy in some states, usually accompanied by chants of "let every vote count."

Let's go back to doing GIS. We note that exporting the NAME and URL fields to the Google Name and Description fields added information to the Google Earth Places pane.
We can travel to a desired district by double clicking on the Name next to the pushpin icon.

Google Earth will immediately zoom us to the district for Congresswoman Linda Sanchez in the Los Angeles area.

Google Earth is smart enough to know a URL when it sees one, so it shows the URLs in the Description field as live links. If we double-click on one of them we launch the browser built into Google Earth. We'll click on the Sanchez home page.
...and there we see the Congresswoman herself. Nice pearls!

We can click on the URL for Trent Franks to see his web site as well:

Interesting to see the PhotoShop manipulation of the background scene, which has been extended to the right through mirror repetition. A very nice effect, but like so much in Congress, on both sides of the aisle, not exactly true to reality.

Note: Manifold takes no sides in politics and has no knowledge whatsoever of the politics of the congressional representatives whose districts were picked out by the Gerrymandering rankings. They simply appear because their districts were identified by an automatic formula as especially flagrant examples of Gerrymandering given their perimeter to area ratios. Without any human intervention at all the automatic formula picked out exactly equal numbers of districts from both parties. Gerrymandering is used as an example because GIS is central to Gerrymandering, both as the central tool used to construct biased districts as well as the tool used to reveal them.

Areas Shown as Hatched Lines

Some authors like to show areas using a pattern of hatched lines. This allows a very bright, opaque color to be used that still allows some of the background to be visible. We can achieve this effect by creating a fake area of sorts that is cobbled up from lines arranged into a suitably dense hatch pattern to give the appearance of an area.
This is an advanced method not likely to be used by most people. After all, it’s easiest just to export areas as partially-transparent solid color and be done with it. But Manifold is so good at spatial manipulation and editing that we cannot resist including this method to show how such things are done. What follows is very straightforward and even fun for GIS people but may strike the beginner as annoyingly technical.

This section of the topic assumes the reader is familiar with making selections, using the transform toolbar and understands elementary copy and paste of objects between drawings that are layers in maps.

We've created a map from our drawing of Placer County and have added two new drawing layers, one called Drawing and one called Grid. The Grid layer is the active layer.

We choose View - Grid, check the Show grid box to enable the controls and choose a spacing of 0.01 degrees. We choose a Style of Solid Lines and then press the Create button. After pressing the Create button we uncheck the Show grid box as we don’t want to actually show a grid, we just want to create line objects where the grid would be shown.
A nice dense grid of lines appears in the Grid layer.

Click the Grid layer off so it does not distract. Click the Drawing layer tab so it is active and draw an area in that layer using the Insert Area tool as set forth in the Adding Shapes topic.

Usually, when we want to display an area in Google Earth it is some area that we get by importing a drawing that contains areas. To keep this example visually simple, we'll just create an area freehand using the Insert Area tool. The Placer CA Drawing layer is just being used as a background so we know where we are drawing the area. It doesn't really matter where the area comes from or whether we use a background layer to guide our drawing, as we can still use the techniques in this example regardless of where the areas come from or how many of them there may be.
In the transform toolbar we use the settings shown above with the Clip with (Intersect) operator and press Apply. This uses the area in the Drawing layer to “cookie cut” the grid of lines in the Grid layer. It still works even though the Grid layer has been turned off from view.

We next use the Boundaries operator in the transform toolbar to make a line that follows the edge of the area.

The new boundary line appears in red selection color. We want this line because otherwise the grid of lines in the Grid layer we have just cookie-cut with the previous command will have jagged edges (much as cutting a wire screen leaves pointy wires sticking out along the edge) and we would like to have a nice, neat line around the edges.

Next, with the Drawing layer still the active layer, click onto the area to select it and then press Delete to delete the area object. That will leave just the boundary line. (This step is not illustrated.)
Click on the Grid layer tab to turn on the layer and to make the Grid layer the active layer. We see that the gridlines cut out by the Clip with (Intersect) operator are still selected. Use Edit - Copy to copy these lines.

Click off the Grid layer and then click on the Drawing layer tab to make it the active layer. Choose Edit - Paste to paste the lines copied from the Grid layer into the Drawing layer. Press Edit - Select None to deselect all objects in the layer to get the view above. We've also reduced the opacity of the Placer CA Drawing layer so it does not visually interfere so much.
We change the name of the Drawing layer to Study Area to give it more credibility as a "real world" example. Next, we change the foreground color of lines in the Study Area drawing to a bright color so they will be more visible when viewed in Google Earth.

We open the Study Area drawing in its own window. All the work in the previous steps boils down to this one drawing, a neat section of grid lines cut out to fit an area we wanted to show, surrounded with a neat boundary line that exactly fits the edge of the area. Better still, this is a true GIS drawing that is perfectly georegistered and exists exactly in the region where it was drawn in Placer County.

We cannot create such a drawing in non-GIS tools like Illustrator because such packages do not create georegistered drawings. Without a true, georegistered existence within a real projection the lines could not be displayed in their true location and scale within Google Earth. Without some sort of background map layer to provide a visual context for the above drawing we might not notice it is indeed georegistered unless we pass the mouse cursor over it and see the geographic coordinates reported in the status bar, but it is still nonetheless completely and perfectly georegistered in a way that only a GIS package can do.

Exporting this drawing to KML takes no time at all. As before, with the drawing open we choose File - Export - Drawing, in the Save as type box we choose KML / KMZ Files, provide a suitable file name such as Study Area.kml (don't forget the .kml extension) and press Save.
We now can double-click the Study Area.kml to launch Google Earth to display it.

If Google Earth has been left open with the previous drawing of Placer County lines displayed, double-clicking the Study Area.kml drawing will display both sets of lines at once.

If Google Earth has been closed, then double-clicking the Study Area.kml drawing will launch Google Earth and display just those lines.

Note how precisely the grid lines forming the grid and the boundary line created from the edge of the area fit together. We can zoom however far we like into these lines and they will fit together seamlessly, because they have been built using the extraordinary precision of Manifold.

This example has been written using a single, simple area created freehand but the techniques it shows can be used with "real life" areas that are far more complex.
For example, the area above shows a contour area generated with the Contours command to show regions between 1000 feet and 1200 feet above sea level in the sample Montara Mountain digital elevation data SDTS file. We have been careful to re-project all components into Latitude / Longitude projection to assure a fast export.
Following the procedure given in this topic allows us to show that area in Google Earth by creating a KML file, seen above in Google Earth. That diagonal furrow, by the way, running just to the left of highway 280 is the San Andreas fault.

**Exporting Images to KML**

There's one last tool we have in our arsenal of techniques for exporting data to KML and that is to export an image. Images may be used to show the images themselves for special effects, to represent areas, or even to show surfaces as images for special effects or to display gradient data.

This example shows how to represent areas using an image, continuing with the same map used earlier.
We begin by adding a **Circle** drawing to the map and then we create a circular area using the **Insert Circle** tool. We format the area with yellow background color. Creating the circle in the map allows us to guide the creation of that circle using the background drawing of Placer County as a visual reference.

We open the new drawing in its own window and zoom in to the circle.
We use Tools - Make Image to make an image of suitable resolution.

We open the image in its own window and see it has some white pixels and is larger than necessary.
We crop the image down in size and then select the white pixels.

We delete the white pixels leaving yellow with transparent pixels. We export this image to KML in the usual way. This creates both a KML file and an accompanying .tif file. Both files must be kept together and provided to our friends if they would like to see the image in Google Earth.
We double-click open the KML file and the accompanying .tif is automatically loaded into Google Earth. We've kept a Google Earth session open after previously loading the Study Area.kml file so the contents of the two .kml files can be compared.

**Important:** For this example we've created a KML file so that it is clear how Manifold creates a .kml and an accompanying .tif image file. In "real life," when we export images we use KMZ format, ending the filename in .kmz. Manifold will then create a single “zipped” .kmz file that contains the image within it. This is far preferred to using .kml because then we don’t have to worry about keeping two files (the .tif and the .kml) together for use.

Note that the circle is no longer a circle. That is because drawing a circle in Latitude / Longitude projection results in an ellipse on the actual Earth's surface at the latitude of Placer County, and that is how it is shown using the visual display (a type of projection) employed by Google Earth. Looking carefully at the Study Area shape we can see it too is somewhat different in shape than it appeared in Manifold in Latitude / Longitude projection, as expected.

Note also that just as with drawings, we cannot create such an image in non-GIS tools like PhotoShop because such packages do not create georegistered images. Without a true, georegistered existence within a real projection the image could not be accurately displayed within Google Earth. To prepare images for accurate display within Google Earth we must use a package with real GIS capabilities.

Display Demographic Data in a Thematic Map

A frequent use of Manifold System is to display data on maps or drawings by coloring areas or points in a range of colors corresponding to the data values. Such a display is said to be thematically formatted and such maps are called choropleth or thematic maps.

**Important:** If you have installed 64-bit Manifold, do this example in 32-bit mode by launching Manifold System using the *Manifold System (32-bit)* shortcut. See the note on 64-bit Manifold at the end of this topic.

There is a huge amount of data available for download by Internet. In the case of the US, Manifold FTP sites and Census Bureau sites provide demographic data for US States, US Metropolitan Statistical Areas, and for the World by country. This data is very useful for the creation of thematic maps and for statistical analysis. In addition, numerous other sources on Internet provide downloads for vast amounts of statistical information.

Demographic data on the Internet is provided mostly in the form of database files, such as Access .mdb or dBase .dbf files. To create maps using this data, we follow a four step process:

- Find and import an appropriate base drawing to display the data (such as the various world, US states or other drawings provided on the CD).
- Import or link the table containing the demographic data of interest.
- Add a relation to the drawing’s table with the demographic table that makes fields of interest from the demographic table appear within the drawing’s table.
- Thematically format the drawing using fields of interest.

For the above process to work, the base drawing and the table containing the demographic data have to share at least one field in common that can be used as a key field. For example, if we want to display demographic data for each state in a drawing of the United States, both the drawing and the data table must each have a field that identifies the state (such as a state name field or two letter postal abbreviation).

In this example, we will use the *States_thematic* map and a table from the *StatesVital.mdb* database. Both of these files are located in the help examples folder on the Manifold CD. The example assumes you are familiar with basic Manifold concepts such as importing drawings and tables, adding relations and applying thematic formatting.

**Step 1:** Import the States_thematic drawing.

We begin by importing the *States_thematic.mfd* drawing into the project using **File - Import - Drawing**. Check all of the boxes to import all of the fields in the **Import MFD File** dialog.

The *States_thematic* drawing shows US States as areas, including a FIPS code for each state.
We can see the fields in this drawing's table by double clicking the table open in a table window.

**Step 2: Import the demographic data table.**

We import the StatesVital.mdb table into the table by choosing File - Import - Table. [If we desire a more dynamic link to the data, we could link the table using File - Link - Table - see the discussion at the end of this topic.]

When we open the StatesVital.mdb file we will see the Import MDB File dialog.

For this example we will import only one table by clicking on Death Rates by Leading Cause and pressing OK.

If we double click open this table after importing it we will see it is a very interesting table providing statistics on death rates from heart disease, cancer, accidents, motor vehicle accidents and many other causes of death for the various states. The rates are per 100,000 resident population in 1994.
So far we have imported a drawing and a table. If we look at the project pane we will see the States_thematic drawing with its associated table as well as the Death Rates by Leading Cause table.

Note that this table includes a FIPS field that contains values that match up to the FIPS field that is in the drawing's table. This is a very important observation, since we will be using the FIPS codes in the thematic states drawing to match the FIPS codes in the demographic data table.

**Step 3: Add a relation to the States_thematic drawing's table.**

Adding a relation to a table is simply adding a column to the table that is taken from a different table. To add a relation to the States_thematic Table, we click it open and then choose Table - Relations.

The Relations dialog for the table opens with no relations, since none have yet been added. We press the New Relation button to add a relation.
The Add Relation dialog asks us which fields will be used to match up records between the States_thematic Table and the new table from which we will bring in a column. In the pane on the left we choose FIPS as the field to use for the States_thematic Table. The combo box over the pane on the right allows us to choose which table will be used to supply fields for this relation. Since we have imported only one other table it is already loaded in the combo box. We choose FIPS in the pane on the right to use as the key field for the Death Rates table. Press OK. Note that it is a happy accident that the key fields on both sides have exactly the same name. The important thing is that the contents of the fields correspond.

Back in the Relations pane we now have a new relation added in the upper pane. This relation uses the FIPS field as a key to bring columns in from the Death Rates table using the FIPS field in that table as a corresponding key. The lower pane shows various cheerful columns available from the Death Rates table that we can bring into our States_thematic Table as relations.

We will check the Accidents and adverse effects rate box as well as the Cancer Rate, Cerebrovascular disease and Homicide (scrolled out of view in the illustration) boxes. Press OK.
Like magic, new columns such as Accidents and adverse effects rate column appear in the States thematic Table. (If you don’t see the columns, use View - Columns to click them on).

We can see the columns better by using View - Columns to hide the other fields in the table and show only the state name field and the new columns. The new columns provide data from the Death Rates demographic table.

**Step 4: Apply thematic formatting to drawing.**

We click onto the drawing to move the focus there.

We will thematically format the drawing by changing the background (“fill”) color of the areas. To do this, click on the area background color well.
In the pull down color menu, choose Theme.

The **Format** dialog launches with default values. We will change the default values by changing the choices in the **Field**, **Method** and **Palette** boxes. We will also check the **Preview** box so we can see a preview of the effects in the drawing window.
We choose the *Accidents* column in the field box and the *Natural Breaks* method. We choose *Reds to Yellows* as our color palette and press *Apply*. The resultant colors are nice, but since we are indicating death rates we would prefer to have redder colors indicate higher values.
Pressing the **Reverse** button reverses the colors so that redder colors are used for higher values. Press **OK** to apply the thematic format.

The resulting drawing shows how various states compare in terms of accidental death rates (excluding motor vehicle accidents). It's no surprise that states representing a frontier, outdoors lifestyle such as Alaska, Idaho, Wyoming and Montana have higher accidental death rates than do states with population concentrated in urban areas. However, why the cluster of high accidental death rates in the deep South? Why does New Mexico have a significantly greater rate of accidental deaths than Arizona? Could it be that a higher population of retirees in Arizona than in New Mexico skews mortality statistics away from accidental deaths?

To see the other demographic data we imported we can open the thematic format dialog and change the field used.
For example, we could choose **Cancer rate** as the controlling field and press **Apply** (and then also press **Reverse** to reverse the present color range) to see the states colored by cancer rates.

This is a very interesting drawing. Note that Utah is exceptionally low in cancer rates while the Rust Belt, Appalachia and the southern regions feature high cancer rates. As expected, Florida has high rates as well, perhaps from the high percentage of older residents. We’d bet that this map would be very similar to a map created of smoking rates per 100,000 citizens. Note that Utah has a high percentage of Mormons who as a statistical cohort tend to show a bias against smoking. Both West Virginia and Pennsylvania have high cancer rates, no doubt due to the higher percentage of persons occupied in coal mining in those states. An anomaly: why the higher cancer rates in Maine?

Finally, we will look at death rates by homicide (murder). To do so we open the **Format** dialog one more time and choose **Homicide rate** as the controlling field, press **Apply** and then press **Reverse**.

The **Natural Breaks** algorithm assigns states to intervals based on clustering of homicide rates. The drawing shows a classic observation, that increased homicide rates are correlated with warmer weather. New York state and the District of Columbia (the seat of Federal government in the US, too small to be seen in this zoomed out view) are clear exceptions.
The States_thematic Drawing

For the convenience of users, we have provided the States_thematic drawing that shows Alaska and Hawaii in the same view as the lower 48 US states. Here is how it was created:

1. Project the States map into Lambert Conformal Conic projection using an origin approximately in the center of the US.
2. Move Alaska and Hawaii next to the lower 48 states.
3. Resize Alaska to reduce the size (using the Scale transform) and rotate it counter clockwise about 28 degrees (using the Rotate transform).
4. Resize Hawaii to enlarge it (using the Scale transform) and rotate it about 30 degrees counter clockwise.

This drawing is useless for serious measurement since Alaska and Hawaii have both been re-scaled and moved, but it does provide a handy drawing for presentations. Just make sure to note somewhere that Alaska and Hawaii are not shown to scale!

Using drawings such as the States_thematic drawing which take geographic entities and apply crafty GIS tricks to move them into different locations and scales within what is purportedly a “real” projection is in some respects an amateur hack, beloved though it may be for expediency even by professionals. Sometimes it is best to simply cringe, clench our teeth and just do what works quickly.

A more elegant and rigorous way to accomplish a presentation like that of the States_thematic drawing is to use a print layout that has different views in play as elements in the layout. Even within an IMS application we can code a web page that uses frames to show multiple IMS views of multiple maps that contain the same drawing, but with different views or projections used so that the continental US as well as Alaska and Hawaii can all be present on the same page.

Discussion

This example explored a few fields from one table out of many thousands of fields available. The same methods may be used to explore demographic data downloaded from the Manifold FTP site or from other web sites, such as the Census Bureau's web site. For example, from the Manifold FTP site we can get and explore the WorldData.mdb database of world demographic data in conjunction with the World_demographic drawing. All of the tables for world data are in the one WorldData.mdb database file.

Note: Manifold FTP sites (drill down through the Manifold web site to find them) require an FTP client that can autoswitch between PASV and non-PASV modes. Ordinary browsers usually won't work, so acquire and learn to use a dedicated FTP transfer program. See the notes on the Manifold web site for more about using FTP.

This example imports an Access .mdb table to keep all parts of the example conceptually simple and as transparent as possible for new users. After all, most Microsoft Office power users know all about how to create a new Access table and save it in an .mdb file. It would be just as easy to import or link a table from some other data provider, such as a table within an SQL, Oracle, IBM DB2, MySQL or other more sophisticated database system.

A more advanced approach than importing the table would be to link a table into the project to be able to exploit the dynamic properties of linked tables within the project. See the Importing and Linking Tables topic for information on linked tables. If the table were linked, then any change in the external database file or system that provided the table would be automatically reflected in the linked table. For example, suppose the table came from a SQL Server table that gave the total number of automobile accidents per state for the previous week. If we linked the table and then formed a relation between our drawing's table and the linked table, any change in the external SQL Server table would automatically be updated in the drawing as well.

We could exploit this by, for example, creating a Manifold IMS web site that showed a thematic map of the United States showing the rates of automobile accidents in the preceding week, where the data to color the map would be automatically taken from the originating SQL Server table. As our other programs or user interfaces updated the SQL Server table the Manifold IMS display would always be automatically up to date as well.

Tech Tips
Be alert to possible problems when using fields as key fields to form relations. Tables may store information differently than expected. For example, the FIPS codes are stored as text strings in both the States_thematic Table and the StatesVital database even though they are numbers. The text string "35" is not the same as the text string "00035" or as "35.0" even though humans would read all three text strings as the same numeric value. Manifold, however, would not be able to match the string "35.0" to the string "35" in the automated key field matching process. If your drawings and databases use inconsistent representations change the types of the fields to match. You may also have to use Transform toolbar operations to alter field contents into compatible form.

The States_thematic Table has FIPS codes in the "concatenated" format favored by the US Government for use when States and Counties might be in the same database. These are five character codes where the first two characters give the state FIPS code and the last three characters are significant for the county within the state. Therefore, "23000" is the FIPS code for Maine and "23003" is the FIPS code for a county within the state of Maine.

One often encounters State FIPS codes in non-concatenated form. In such instances, the FIPS code for Maine is 23, not 23000. A further complication is that Federal databases often express the FIPS code as a text string and not as an integer. Finally, Federal databases often utilize FIPS codes for countries that are multiplied by 100 and also contain extra leading "0" characters. All of these issues may arise when one combines data and maps from various sources. Each may be easily dealt with through the use of the Transform toolbar or the Convert Type command in the table column head context menu.

How to produce leading zeros with the Transform toolbar? Suppose we wish to create text "numbers" like "00035." Start with an integer field. Add a large multiple of ten (say, 1,000,000) to that field. Convert the integer field into a text field. Cut off as many starting characters as desired, leaving as many leading zeros as desired.

Important Note when Using 64-bit Manifold Editions

Due to a lack of required Microsoft facilities in 64-bit Windows systems, Manifold in 64-bit mode cannot export, import, export or link to DB, HTML, MDB, XLS or WKx format files. This includes no access to the MDB parts of Manifold MFD and MapInfo TAB imports. The workaround for importing or exporting such files is to launch Manifold in 32-bit mode by using the Manifold System (32-bit) shortcut, perform the export from or import into a .map project file and then re-launch Manifold in 64-bit mode using the Manifold System (64-bit) shortcut. Linking is more complex: the data must be in some format usable in 64-bit mode within 64-bit Windows systems, such as a SQL Server database. Alternatively, the data can be kept within a Manifold .map project file and linked using the Manifold ODBC driver.

Thematic Formatting Example

Thematic Formatting and Labels
Selection in Images

This example topic shows use of selections in an image, using the globe.jpg sample image from the Manifold Release CD. We will use saved selections and selection commands to select only South America. We then apply visual effects only to the land area of South America.

Step 1: Create a new project

Use File - New to create a new project.

Step 2: Import the globe.jpg image

Use File - Import - Image to import the globe.jpg image into the project.

Step 3: Open the image in an image window

Double-click on the image in project view to open it. The system will display an info bar warning that the projection of the image has not been verified. In this example, we are not concerned with the projection of the image, so click the info bar to launch the Assign Projection dialog and click OK in the dialog to confirm that the projection is OK.

Step 4: Increase contrast

We will increase the contrast in the image to make it easier to "touch select" the pixels representing the ocean. Do this by choosing Image - Adjust - Brightness / Contrast and entering a value of 40 for the Contrast. Enter the "40" value either by moving the slider bar or by clicking into the number box and entering 40 from the keyboard. Click OK.
The result is an image with brighter light tones and darker dark tones.

**Step 5: Open the saved selections pane**

We will be saving some of the selections we make. Open the saved selections pane by choosing **View - Panes - Selections** or by pressing the **SHIFT-ALT-S** keyboard shortcut. Drag the saved selections pane to a convenient place on screen where it does not cover South America.

**Step 6: Select oceanic pixels**

Using Select Touch in Replace Selection mode, **SHIFT** - click anywhere on an ocean to select all pixels in the ocean, as well as all other pixels with this color. The **SHIFT** click is an instruction to select all pixels of the touched color, including those pixels not contiguously connected to the touched pixel. This command is necessary because at the resolution of this image there is not a continuous run of pixels between the Red Sea, Black Sea and other oceanic areas. Therefore, simply clicking on an ocean area will not also select the isolated pixels. Using a **SHIFT** - click will select the isolated pixels as well.

The result is that all pixels in oceanic regions are selected.

Note: Using **SHIFT** - click to select all of the oceanic areas at once depends on the color used for oceanic pixels being unique. If the same shade of blue also appeared within continental areas we could not take this approach. Instead, we would use Add to Selection mode and then with Select Touch we would click the main ocean region, the Black Sea, the Red Sea and so on to build up the selection by clicking each contiguous region of pixels having the color we wish to select.

**Step 7: Save oceanic selection**

In the saved selections pane, click the **New Selection** button to add this selection to the saved selections.

**Step 8: Change the saved selection's name to "Oceans"**
In the saved selections pane, double-click into the “Saved Selection” name and change it to "Oceans" and press Enter.

**Step 9: Select overlapping circles to cover South America**

Clear the selection.

With selection mode set to **Add to Selection**, use **Select Circle on Center** to select a circle that covers much of South America.

Repeatedly use **Select Circle on Center** to cover all of South America with overlapping circles.

We don't have to be very precise, since the next step will trim the selection. We can safely overlap ocean areas.
We only need to be sure that the circles do not overlap land areas (such as various islands) we do not wish to select as part of South America.

**Step 10: Subtract the Oceans saved selection**

In the saved selections pane, click on the **Oceans** saved selection and then press the **Subtract from Selection** command button. The pixels in the Oceans saved selection will be subtracted from the current selection created with overlapping circle selections.

The result is a selection that covers only the land area of South America.

Note: had we wished to see what effect subtracting the Oceans saved selection would have before pressing the **Subtract from Selection** button, we could have checked the **Preview** box in the saved selections pane. This would have previewed the Oceans selection in blue color when the Oceans selection was highlighted. This would let us see how it overlaps the existing selection. For examples of using **Preview**, see the Invisible Pixels and Selection and the Modifying Selections topics.

**Step 11: Save the South America selection**

Just in case we would like to later recall just the South America selection, we can save it in the saved selections pane. In the selections pane, click the new selection button to add this selection to the saved selections.
Double-click into it to rename it to "South America."

**Note:** The selections pane can hold up to six saved selections for each image or surface with a seventh selection reserved for invisible pixels. Drawings and labels components can have seven saved selections.

**Step 12:** Alter only the South America selection

We can pull down the Selection Style menu to choose a **Border** style of selection.

This outlines the selected region with a border line in red selection color so that the red selection pattern does not interfere with our view of the selected region.

We can choose **Image - Adjust - Hue / Saturation** to alter the hue of the pixels in the selected region. Changing the hue to **-90** will shift the colors towards greener hues. Press **OK** to apply the change.
The result is that South America is colored in green hues.

We can use the above techniques to alter the rest of the image as desired. For example, to create the image above we selected land areas in North America using overlapping circles, and then in the saved selections pane we used the Subtract from Selection command button to subtract the Oceans selection and to subtract the South America selection. We then changed the hue of the remaining North America selection. We also selected the Oceans selection again by clicking on the Oceans selection in the saved selections pane and choosing Replace Selection. We then reduced the brightness of the ocean regions to make these pixels black. Finally, we deselected everything and applied Image - Effects - Relief to give the continents and mountain ranges a 3D appearance.
Displaying Data in a Gradient Map

In the Display Demographic Data in a Thematic Map topic we saw how Manifold can display data by coloring the objects in drawings. At times we have data that is point data which we would like to display in the form of a gradient map, like that illustrated below, that shows smooth changes from one color to another that reflect the values of data in the map.

Gradient maps are usually created from data points. The task of the GIS software is to smoothly interpolate data between the points and to then color it as we desire. In Manifold, we use surfaces to easily accomplish these tasks.

This example shows how to take a collection of data points and create a gradient map. There are two main parts to this procedure: The first part is creating a surface from a collection of points and then coloring it. This is very fast and easy. The second part is trimming the surface so that it neatly aligns with other drawings or maps we might create. This takes a few more steps.

We begin with a drawing of data points. Each point has one field, that gives the percentage of students who drop out of school before completing high school.
We created this drawing by opening the `Counties98_demog.map` in the `Data\US` folder of the Manifold CD. We deleted all counties in the US except those in the continental, lower 48 states. We then created centroids for those counties and used those points as a drawing of data points.

The points are positioned at approximately the center of each US county. The drawing showing the points has been projected into Lambert Conformal Conic projection to show a more natural view of the US.

If we show the drawing of points together in a map with a drawing of the United States we can see how the data points are distributed throughout the country. (Some data points in Southern California are offshore, apparently the result of data points collected for offshore islands such as Catalina Island.)

**Step 1: Create a Surface**

Creating a surface is easy. Right click on the data points drawing in the project pane and choose **Copy** from the context menu. Next, right click on an empty part of the project pane and choose **Paste As - Surface**.
The Paste As Surface dialog pops up. By default, it offers a pixel size in meters, which we will adjust to a pixel size of 5 x 5 kilometers, for a total image size of 912 x 580 pixels (shown in the lower left corner) and about 2 megabytes. There is no extremely precise reason why we chose this pixel size and resulting surface size…it just seems like a good number considering the density of the points and the size of the United States. We check the Use radius option with a radius of 100 km to constrain the interpolation to a reasonable distance from the available data points.

The result is a surface. We will rename this surface Data Surface. When we open the surface we see the display above, which is something of a disappointment before it is colored with a palette. Note that some regions in the Southwestern part of the US are not filled in by the interpolation. The default interpolation radius and other parameters we chose do not allow the interpolation to entirely fill in this region because points there are too sparse. That's OK: Sometimes it is more important to leave an interpolation unfilled to warn the viewer that data for that region is lacking than it is to form a display that is beautifully filled in but fundamentally deceptive.

Note also that the surface has been created using the same projection as the drawing of points from which it originated. It is precisely georegistered.

**Step 2: Color the Surface**

The grayscale display is so ugly that before we do anything else we will color it using more appealing and informative colors. To color the surface with a palette we choose the View - Display Options dialog.
The dialog opens with default settings not using any palette to color the surface. For now, we will leave the Shading and Autocontrast options checked. Choose Spectrum for the Palette.

Press the Apply button in the toolbar to apply the palette to the Colors pane.
The result is a series of equal intervals colored by the palette colors. We will adjust these by manually clicking into each interval number and editing it to make it a round number.
Examples

The above intervals seem reasonable at first glance, as a casual effort to round the intervals automatically created for the Spectrum palette. However, note that whereas the automatically created intervals were exactly the same our casual rounding to the nearest five or tens place has created uneven intervals. Some intervals are five units apart (such as 20.00 to 25.00) and some intervals are ten units apart (such as 30.00 to 40.00). This is sloppy.

If we were more rigorous and creating this example for a paper for publication and not just as an example of how to operate dialogs, we would probably have used intervals that were exactly the same size. This would have involved some tinkering to get even intervals that were reasonably well rounded. For example, we might have used intervals of 8, 16, 24, 32, and so on, or we might have used 20, 25, 30, 35, 40, 45 and 50.

Press OK to apply the display options to the surface.

The result is that the surface is neatly colored. Dark blue colors indicate regions where most students finish high school. Yellow, orange and red colors indicate regions where very many students fail to finish high school.

If we show the new surface in a map overlaid by the drawing of data points we can see the relationship between the points and the surface created from them. Note how the surface cannot be completed in the Southwest because the allowed interpolation radius does not extend far enough to fill in the gaps between the sparse points in that region.
If we overlay a drawing of the United States (the US_Main.mfd drawing found on the Manifold CD, with area background set to transparent color) we can see that the interpolation extends beyond the geographic borders of the US.

**Step 3: Trim Surface to US Boundaries**

Although at this point we already have a perfectly functioning gradient map, as a matter of neatness and better presentation we will trim the surface so that it does not extend beyond the borders of the US.

We begin by showing a drawing of the United States (the US_Main.mfd drawing) in a map together with the surface.
We select all of the areas in the US_Main drawing clicking on its layer tab in the map and choosing Edit - Select All (or by pressing CTRL-A).

Next, we right click on the US_Main drawing layer tab and we choose Transfer Selection.

In the Transfer Selection dialog we choose Data Surface as the component to modify, using the US_Main drawing. Since this is the only component in our project that has a selection in it, it is the only component that appears in the Using pane. Press OK.
The selection will be transferred to the surface, as we can see by clicking off the US_Main drawing that overlays it.

To trim the surface we choose **Edit - Select Inverse** (or, press `CTRL-I`). This inverts the selection so that all pixels are selected except those that had been previously selected. Choose **Edit - Delete** (or, press the **Delete** key) to delete these pixels.
The result is a surface that has been neatly trimmed to the borders of the US.

To provide some context to our map we can turn on the US_Main drawing again, set the background color of areas in the drawing to transparent color and then change the foreground color to medium gray. We can then change theOpacity of the US_Main drawing to 50%. This will provide a faint overlay of state and US boundaries to provide context for the gradient map underneath.
To complete the map, we can add a legend, editing the values in the legend so that the numbers are not too long. See the Adding a Legend example topic for a step by step procedure for adding a legend.

**Comments**

This example used a collection of data points to create a gradient map. The data points used were US Census data from 1990 that gave the dropout percentage for each US county similar to what is in the counties maps on the CD such as *Counties98_demog.map*. To create the data points we simply took the centroid of each county within the continental US.

This is something of a contrived example that takes advantage of a handy data set. To display demographic data, such as the dropout percentage, that is collected on a per-county basis it might make more sense to use a thematic map like that shown in the Display Demographic Data in a Thematic Map topic.

If we thematically format a map of US counties with the same data and the same palette we can compare the visual effect of the thematically formatted drawing to that of the similarly colored gradient map.
In one sense, the drawing is more accurate because this particular data set was collected for each county. In another sense the gradient map surface is more accurate because human phenomena like populations and educational achievement do not suddenly change at the sharp boundary of a county. They are more likely to smoothly vary from place to place.

Gradient maps are typically used to show data arising from natural phenomena that are fundamentally continuously variable over a geographic region, so that one would see a smooth variation beyond the boundaries of just one county or one state. For example, temperatures, pollution, the percentage of ozone in the upper atmosphere or the distribution of algae in a region of an ocean are all cases where we would expect there to be some smooth variation between data points recorded. The technique described here works with all these cases.

The process is always similar: acquire the data points, noting the latitude and longitude at which each sample was collected. Collect the data points into a geocoded table. Create a drawing of points from the geocoded table and then create a surface and color the surface as desired. If desired, trim the surface neatly to whatever geographic boundaries are convenient for the area of interest.

Note that we could create the surface directly from a geocoded table by copying the table and pasting it as a surface. However, it is usually wise to create a drawing of points from the table first as a way of checking that the points really are in the region we desire (and no systematic error has occurred) by viewing them overlaid upon a drawing showing the area of interest.
Turning Layers Off/On by Zoom

We would often like to create a map where different layers turn on and off as we zoom in and out. This allows us to hide dense layers when zoomed far out and to make them visible when zooming in. This example creates a simple map of Mexico with different layers.

Important: If you have installed 64-bit Manifold, do this example in 32-bit mode by launching Manifold System using the Manifold System (32-bit) shortcut. See the note on 64-bit Manifold at the end of this topic.

We would like to create a map of Mexico that has boundaries, highways and railroads layers plus a drawing layer showing data points and a labels layer.

Without the use of zoom ranges, the map looks very busy when zoomed out.

If you do not have an analogous map of your own to use and wish to follow along in this example, do the following to create a map like the one illustrated in this example:

Step 1: Import the drawings to be used in the map

Drawings used in this example are in the Examples directory of the Manifold CD. Use File - Import - Drawing with file type set to MFD Files to import Mex boundaries.mfd, Mex highways.mfd and Mex railroads.mdb.

This creates three drawing components in the project pane, as seen above.

Step 2: Create a Labels Component

Create a new labels component by clicking on the Create button in the project pane toolbar and choosing a new Labels component (or, by choosing File - Create - Labels from the main menu).
In the Create Labels dialog, click on the Mex boundaries drawing component. This will make its fields appear in the dialog's Columns pane. [For the sake of brevity in this topic henceforth we will refer to the Mex boundaries drawing as simply the "boundaries drawing" and likewise for the other drawings used.]

![Create Labels dialog]

In the Create Labels dialog, double-click on the Place name field to add it to the labels text and press OK.

![Creating labels for the map]

A labels component appears in the project pane, indented under its parent boundaries drawing.

**Step 3: Create a Map**

To create a map, we use File - Create - Map and in the Create Map dialog check the boxes for the components we wish to appear in the map.

![Create Map dialog]

In the illustration above we named the new map Mexico. We also changed the default order of the layers using the Move Up and Move Down buttons so the map will be created with the order of layers seen above.
The result is a new map component in the project pane. We can double click the map to open it in a map window. Use Zoom commands to zoom as desired into the map.

**Step 4: Apply a projection to the components**

Zoom ranges only work with projected components. They do not work with components in Latitude / Longitude that have not yet been projected. The fastest way to project the components in the map is to first apply a projection to the map using the Edit - Assign Projection dialog. Choose the Orthographic projection centered on Latitude 24 and Longitude -102 (about the center of Mexico, the defaults suggested by the Suggest button). There will be little change in the appearance of the map since the Orthographic projection so close to the Equator is visually very similar to Latitude / Longitude coordinates.

To apply the projection to all of the components in the map, first confirm the original projection of each component by using the Assign Projection dialog, and then project each component to the projection of the map by right clicking its layer tab and choosing Project to Map. This will re-project the component into the same Orthographic projection used by the map. Alternately (and more slowly) in the project pane double click open each of the components in turn, choose Edit - Change Projection and set the projection to Orthographic with a Latitude center of 24 and a Longitude center of -102.

**Step 5: Format the Map Layers**

Seen in default formatting, the map is somewhat confusing.

We will make it more comprehensible in two steps: first, we will apply formatting to distinguish different layers by color and second, we will use zoom ranges to turn layers on and off as needed as we zoom. Apply formatting using the format toolbar using the methods described in the Formatting Drawings topic.

Using the format toolbar change the foreground color for lines of the railroads layer to a dotted style using dark blue foreground and white background colors. Leave the highways layer in the default colors. Change the background color for areas in the boundaries layer to your choice of color (we used a beige color in this example).
The illustration above shows a cluster of green points in the center of Mexico. This example uses a points layer for illustrative purposes. To create such a layer, right-click on the highways layer tab in the map and choose **Add - New Drawing**. This will add a new drawing layer (and create the drawing in the project pane) as a layer just above the highways layer. Use the Insert Point tool to add some points in the center of Mexico and then use the format toolbar to change those points to a bright green background color.

**Note:** The Mexico drawings provided in the **Examples** folder on the Manifold CD don't have any points in the line drawings such as the highways or railroads drawings. This is unusual, since most drawings created for transportation analysis have points at the ends of each line to enable them to be used for network analysis. If you use different drawings in the examples, you may find that line drawings are imported with numerous points. These may be easily deleted. See Point Styles and Sizes for examples.

**Step 6: Open individual components and assign zoom ranges**

In the following section we will open each drawing in its own drawing window. Do this by double clicking on the component in the project pane. It will open in a drawing window (or, a labels window for the labels component). Note that we can have a component window open at the same time we see that component as a layer in the map window.

Let's begin by adjusting the zoom range on the **railroads** drawing layer. To do this, we double click open the **railroads** drawing in its own window and then choose **View - Properties** and click the [...] button to the far right of the **Zooms** caption.

This opens the **Zooms** dialog. By default the zoom range displays the drawing from the **Minimum zoom** (lowest value) to the **Maximum zoom** (highest value). The **Current Zoom** number shows the current zoom in the opened
railroads drawing window. It will vary as we zoom in or out of the window. It has no effect in setting zoom ranges except to provide a guide that may be used to estimate which zoom values to enter in the Minimum zoom or Maximum zoom boxes based on the current appearance of the component window.

In the Maximum zoom list box, we will choose the 1:10000000 preset and then press OK to apply this new zoom range to the drawing. This means that the railroads drawing will be visible in the map from any lowest zoom level up to a highest zoom level of one to ten million. At higher (further out) zoom levels the drawing will not be displayed.

If the map is zoomed out farther than one to ten million the railroads layer will disappear. There will be no change visible in the drawing window for railroads since zoom range only affects the visibility of drawings in maps.

We can repeat this process with the other drawings in the map. For example, we can alter the zoom ranges for the highways drawing.

We double-click open the highways drawing in a window. We can then choose View - Properties and click the […] Zooms button to set zoom range for the highways.

By default the Minimum zoom and Maximum zoom boxes offer preset zoom ranges as factors of ten. We can also enter a zoom range that is not an even factor of ten.

For the Minimum zoom range we can choose 1:1000000. For the Maximum zoom range we can enter 3000000 to specify a zoom range of 1:3000000. These values mean that the highways layer will be displayed in maps at zoom levels between 1:1000000 and 1:3000000. At zoom levels below 1:1000000 or zoom levels above 1:3000000 the highways layer will not be displayed in maps. Applying this zoom range to the drawing instantly
causes the highways to disappear from the map if the map window is zoomed farther out than one to three million.

Next we can click open the points drawing layer and set the zoom range for the points.

We will set it from any lowest zoom up to a highest Maximum zoom value of 1:1000000. In the map window, the data points layer immediately disappears if the map window is zoomed higher than 1:1000000.

Finally, we can click open the labels component and set the zoom range for the labels.

We will leave the zoom range for Minimum zoom blank so there is no minimum zoom value and we will set the Maximum zoom to 1:5000000.

Within the map window we can now zoom in and out and the drawing layers will appear as directed by the zoom ranges we have specified.
Suppose we begin with the zoomed out view seen above. The view is zoomed out farther than 1:10000000 so no layers except the boundaries appear. As we zoom in, the different layers will appear. We will zoom in to the central part of the illustration in each case.

As we zoom in closer than a scale of 1:10000000 the railroads appear in dotted lines.
As we zoom closer than 1:5000000 the labels layer appears. Labels, surfaces and image components can have zoom ranges specified as well as drawings. Assigning different zoom ranges to different labels layers is an essential method to keep maps from becoming cluttered with labels that are too close together.

As we zoom to below 1:3000000 the highways layer appears.
Finally, as we zoom to below 1:1000000 the highways disappear, leaving only the railroads, labels and data points layers.

**Notes**

What does a scale of 1:1000000 (one to one million) really mean? It means that what is shown in one unit of measure on the computer screen is one million of those units on the surface of the Earth. If we measured a feature on the screen that was five centimeters wide it would be five million centimeters (50 kilometers) wide on Earth.

**Important Note when Using 64-bit Manifold Editions**

Due to a lack of required Microsoft facilities in 64-bit Windows systems, Manifold in 64-bit mode cannot export, import, export or link to DB, HTML, MDB, XLS or WKx format files. This includes no access to the MDB parts of Manifold MFD and MapInfo TAB imports. The workaround for importing or exporting such files is to launch Manifold in 32-bit mode by using the Manifold System (32-bit) shortcut, perform the export from or import into a .map project file and then re-launch Manifold in 64-bit mode using the Manifold System (64-bit) shortcut.

Linking is more complex: the data must be in some format usable in 64-bit mode within 64-bit Windows systems, such as a SQL Server database. Alternatively, the data can be kept within a Manifold .map project file and linked using the Manifold ODBC driver.
Create a Table and Add Records

This is a small example showing the mechanics of creating a new table and adding records. Manifold has great table and database capabilities. We will often create small Manifold tables as a means of keeping track of things, almost like a GIS personal information manager. Some users will actually pop open tables in Manifold to keep track of logins for emails, the configuration of their systems and other useful information that has nothing to do with GIS or mapping.

In this example we create a small table and enter a series of records. The records will be later be used as control points to georegister an image.

**Step 1: Create the Table**

To create the table, right click into the project pane and choose **Create - Table** from the context menu that pops up.

In the **Create Table** dialog we press the **Add Column** button to create new fields and then for each new field created we double click into the **Name** and **Type** cells to specify the name desired and the data type of that field. Press **Enter** when done specifying the name or choosing the type to accept the choice into the **Name** or **Type** cell for each field.

We create three new columns, called **Longitude** (of type Longitude), **Latitude** (of type Latitude) and **Name** (of type variable length ANSI text). Pressing **OK** in the dialog creates the table.

**Step 2: Add Records to the Table**

The new table is empty. We double-click into the **Longitude** cell for the first, asterisked record to create a new record.
We can then enter in the value for the longitude for the first record. The default display format for latitudes and longitudes in Manifold is decimal degrees. However, Manifold is smart enough to understand almost any reasonable format in which we enter such values. For example, it knows that if we enter \(-122 20\) where the two numbers are specified by a space we mean the values as 122 degrees, 20 minutes West longitude. An entry like \(-122 20 10\) would be interpreted as 122 degrees, 20 minutes and 10 seconds West longitude.

We can press \(\text{Enter}\) to accept the longitude value. The row handle changes to a pencil icon to indicate we are editing the record. We can double-click into the \(\text{Latitude}\) cell for the row and enter \(37 50\) to mean 37 degrees 50 seconds of latitude. Pressing \(\text{Enter}\) accepts the edit into the cell. To create the record we press the row handle.

This creates a new record using the edit values and adds another row with the new row asterisk record handle. Note that when the new record is created it will be displayed in the format specified for that column. Because the default format for latitude and longitude types is decimal degrees, the values in the cells are now displayed in the decimal degree equivalents to the degrees, minutes and seconds notation we used to enter the values.

To add another record we can double click into the \(\text{Longitude}\) cell for the new record.
We add a longitude value and a latitude value and then click on the row handle.

This creates the new record and moves the new record handle down one position.

At any time we can double click into the Name cells for the records to add values there. At any time we can double click into any of the cells to edit the values if desired.

Notes

It’s easy to create new tables in Manifold. After creating a new table we can add records to it or edit existing values. People will often use Manifold tables as personal database managers. These can be saved in a .map file or exported as desired to database formats such as .mdb or .dbf.

Because Manifold can accept different formats for latitudes and longitudes when entering values, we can use tables as a way of converting from degrees, minutes and seconds format into decimal degrees format or vice versa. At any time we can change the format of the column and see the values in different format.

If we wanted to use the table created above for control points, we could create a drawing from it by copying the table and pasting it as a drawing. See the Create a Map from a Geocoded Table example for the step-by-step procedure for doing so.

Tech Tip

Manifold can read so many different database formats that we can use the system as a converter between different database formats. For example, we can read tables from Access 2000 .mdb format and then export them to Access 97 .mdb format. Or, we could read tables in .dbf format and export them in .mdb format.

**Edit a Table with the Transform Toolbar**

It is often the case that a table contains data in a form that we would like to change so it can be more useful. A frequent task is changing coordinates from various legacy formats to modern digital formats.

In this example, we will use the transform toolbar to change the coordinates in a table from old-fashioned latitude and longitude coordinates as seen in the table above to modern decimal degrees as seen in the table below.

<table>

In this example, we will use the transform toolbar to change the coordinates in a table from old-fashioned latitude and longitude coordinates as seen in the table above to modern decimal degrees as seen in the table below.

<table>

</table>

Tables that use decimal degrees for coordinates are geocoded tables and may be immediately used to create drawings.

This example uses a long sequence of very simple steps. It shows a typical use of the transform toolbar to edit tables using temporary columns as a "scratchpad" to save intermediate results. While it is certainly possible for an expert user to simplify this sequence by using Active Columns or a script, for many one-time tasks it is quicker to simply do conversions manually through a sequence of steps than it is to conceive and debug a programmatic conversion.

The table we will be working with comes from the NOAA's "Ocean Relief" CD, which was published in the late 1990's and provides bathymetric data (underwater terrain elevation) for the entire world. The CD also contains a gazetteer, a listing of underwater features with their types, names and locations contained within a table called **BGNGAZ** (apparently a contraction of "background gazetteer").
The table shows latitude and longitude values using degrees and minutes notation (with a space character between the degrees and minutes) and uses a postfix character instead of modern positive and negative numbers to show latitude and longitude quadrants. This is easy to convert.

**Step 1: Prepend "-" Prefixes to South Latitudes**

The table indicates North or South longitudes and East or West latitudes using "N", "S", "E" and "W" postifixes. Our first task is to prepend "-" characters to South latitudes and West longitudes. We may then eliminate the letter postfixes.

We begin by hiding all columns that are not of interest, such as the **TYPE** and **INDEX** columns.

Next, we create a Unicode text column called **tmp** that will be used to store intermediate results.

Using the query toolbar we select all latitude values ending in **S**.
The illustration above shows the table after unnecessary columns have been hidden, the tmp column has been added and records with latitudes ending in S have been selected.

We use the transform toolbar to prepend a "-" character to all selected values in the LATITUDE column. Note that the transform toolbar is auto-scoped, that is, if there is a selection the action of the transform toolbar is automatically applied only to selected records.

The result is that we have prepended a "-" character to all South latitudes.

**Step 2: Prepend "-" Prefixes to West Longitudes**

We use a similar procedure to prepend a "-" character to West longitudes.

We begin by using the query toolbar to select all longitude values ending in W.

Records with West longitude values will be highlighted.

We can then use the transform toolbar to prepend a "-" character to the LONGITUDE values of all selected records.
Because the transform toolbar is auto-scoped only records that are selected will be altered.

**Step 3: Delete "NSEW" Postfixes**

We no longer need the "NSEW" postfix characters and can delete them. We begin by deselecting all records, since we want the following operations to apply to all records.

No records are selected.

Using the transform toolbar we delete the rightmost single character from all records in the **LATITUDE** column.
This step depends upon our observation that the last character in the LATITUDE column values is the postfix "NSEW" character. In some cases, we may be working with a table with unknown characteristics, where there might be a space character or other "white space" character to the left or right of the value. In that case, it would be wise to use a TRIM transform operator to make sure that the postfix character is indeed the last character (remember, white space characters like a space character are still characters).

Using the transform toolbar we delete the rightmost single character from all records in the LONGITUDE column.

We have now successfully converted all latitude and longitude values from "NSEW" postfix notation to ".-" prefix notation for South latitudes and West longitudes.

**Step 4: Convert Degrees and Minutes to Decimal Degrees**

Our next step is to convert the old-fashioned degrees and minutes values into modern decimal degrees form.

We begin by adding a floating-point numeric column called minutes. This will be used as a temporary workspace column when converting text values into numeric values.
The column appears to the right of the previously created `tmp` column.

```
<table>
<thead>
<tr>
<th>trp</th>
<th>Copy Last Token from</th>
<th>LONGITUDE</th>
</tr>
</thead>
</table>
```

Next, we copy the last token from the `LONGITUDE` column to the `tmp` column. If default settings are in play for token delimiters, the last token is simply the two characters after the space in the longitude values.

<table>
<thead>
<tr>
<th>FEATURE</th>
<th>LATITUDE</th>
<th>LONGITUDE</th>
<th>trp</th>
<th>minutes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abbott Seamount</td>
<td>31 18</td>
<td>174 18</td>
<td>18</td>
<td>0</td>
</tr>
<tr>
<td>Abington Reef</td>
<td>-18 00</td>
<td>139 45</td>
<td>45</td>
<td>0</td>
</tr>

<td>05</td>
<td>0</td>
</tr>
<tr>
<td>Adams Bank</td>
<td>-41 20</td>
<td>176 00</td>
<td>00</td>
<td>0</td>
</tr>
</tbody>
</table>

Note how this operation copies the two-character token representing the minutes values from the longitudes into the `tmp` column.

```
<table>
<thead>
<tr>
<th>minutes</th>
<th>Copy from</th>
<th>tmp</th>
</tr>
</thead>
</table>
```

The `Copy Last Token from` operator is only available when copying text information between text columns. We used it to get the minutes portion of the longitude text values isolated in the `tmp` text column. We can now copy the values from the `tmp` text column into the `minutes` numeric column and they will be automatically converted into numbers.

```
<table>
<thead>
<tr>
<th>FEATURE</th>
<th>LATITUDE</th>
<th>LONGITUDE</th>
<th>trp</th>
<th>minutes</th>
</tr>
</thead>
<tbody>

<td>5</td>
</tr>
<tr>
<td>Adams Bank</td>
<td>-41 20</td>
<td>176 00</td>
<td>00</td>
<td>0</td>
</tr>
</tbody>
</table>
```

Although the values look almost the same, the values in the `tmp` column are text and those in the `minutes` column are numbers. Note that leading zeros are lost in the conversion from text to numbers. Numbers may be divided, multiplied and otherwise processed in a way that text values cannot.

```
<table>
<thead>
<tr>
<th>minutes</th>
<th>Divide by</th>
<th>60</th>
</tr>
</thead>
</table>
```

We can use the transform toolbar to divide the minutes values by 60.
This converts the whole minutes values into decimal fractions of degrees. However, we don't need so many digits after the decimal point. We can right click on the column head of the minutes column, choose Format and then change the format so that only three digits after the decimal point are displayed.

This provides a cleaner display with a significant number of digits consistent with the two-digit minutes values originally used.

We now copy the new decimal degrees values back to the tmp column to automatically convert them back into text form.

The result is a table that has text values for decimal degree fractions in the tmp column. We will "glue" these onto the LONGITUDE whole degree values with a few more operations.
We delete the leading zero in the tmp text values using a Delete Left operator.

<table>
<thead>
<tr>
<th>FEATURE</th>
<th>LATITUDE</th>
<th>LONGITUDE</th>
<th>tmp</th>
<th>minutes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abbott Seamount</td>

<td>0.083</td>
</tr>
<tr>
<td>Adams Bank</td>
<td>-41.20</td>
<td>176.00</td>
<td>.000</td>
<td>0.000</td>
</tr>
</tbody>
</table>

This makes ready the tmp text values for appending to the longitude data.

We use the Delete Last Token operator to eliminate the minutes values in the longitudes that we no longer need.

Although the last two digits are gone, there is still an invisible space character at the end of each of the text values in the LONGITUDE column.

We can eliminate the unwanted space with a Trim operation.
The table is now ready to append the values in `tmp` to the values in `Longitude`.

This is easily accomplished with an Append operation in the transform toolbar.

The result is a table that has had longitude values converted from an old-fashioned form into modern decimal degrees notation.

The procedure to convert the values in the `LATITUDE` column is exactly the same. Let's take a look at the first few steps:

We copy the last token from `LATITUDE` to `tmp`.

```plaintext
<table>
<thead>
<tr>
<th>FEATURE</th>
<th>LATITUDE</th>
<th>LONGITUDE</th>
<th>tmp</th>
<th>minutes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abbott Seamount</td>
<td>31.48</td>
<td>174</td>
<td>.300</td>

</tr>
<tr>
<td>Adams Bank</td>
<td>-41.20</td>
<td>176</td>
<td>.000</td>
<td>0.000</td>
</tr>
</tbody>
</table>
```
This isolates the text in the token so that it may be copied to a numeric column.

We copy the *tmp* text values into the *minutes* numeric column.

This converts the values into numbers, which can then be divided by 60, copied back to the *tmp* column to be converted back into text, and so forth. The rest of this procedure will not be shown since it is identical to that used for the *LONGITUDE* column.

After completing the procedure for the *LATITUDE* column we can delete the *tmp* and *minutes* temporary columns. The result is a table that lists features using modern decimal degrees. It is a geocoded table that can be used to create drawings.
Here is an example of a drawing where the geocoded table points are labeled using the values in the **FEATURES** column.

**Comments**

This is obviously a long procedure, but it consists of very simple steps that quickly become second nature to users who need to manipulate tables. Note how the different operations that are possible for text types and numeric types were exploited to get the desired result. Note also how selection was used in the beginning of the procedure to operate on only some of the records.

It’s true that a sophisticated user could write a script, or even an Active Column that would programmatically make the desired conversion. However, it is often quicker to simply use a series of transform toolbar operations, where all results are visually obvious at each step, to accomplish the desired transformation than it is to write and debug a script that accomplishes the same result.

When undertaking lengthy procedures, don’t forget to take a moment to save your work from time to time, just in case a mistake is made that cannot be conveniently undone!
Create a Map from a Geocoded Table

In this example we create a map from a geocoded table created in Microsoft Access. Before beginning this topic, please read the Creating Drawings from Geocoded Tables topic.

Important: If you have installed 64-bit Manifold, do this example in 32-bit mode by launching Manifold System using the Manifold System (32-bit) shortcut. See the note on 64-bit Manifold at the end of this topic.

There are two ways of creating drawings from geocoded tables. A simple, straightforward way if the geocoded table has already been imported into the project is to Copy the table and to Paste it as a drawing. When the drawing is created as a result of the Paste process the coordinates for points in the drawing and their data attributes (if specified for transfer) will be copied from the table. This example shows that process.

Another way of creating a drawing from a geocoded table is to link the drawing to a geocoded table, which might be in the project or might be an external, geocoded table. In this case every time the linked drawing is opened or refreshed it will be dynamically recreated on the fly based on the data in the table from which it is linked. The position of points and their data attributes will be dynamically taken from the table. If the table is altered to add, delete or change the coordinates of records then the points in the drawing will appear, disappear or move as the table records are updated. For an example of this process see the Create a Linked Drawing from a Geocoded Table topic.

The distinction between the above two scenarios is subtle, but critically important. In the first case the spatial data from a table are copied and used to create a new, independent drawing is created. In the second case, a "virtual" drawing is created that remains linked to the table and is controlled by it.

Let's begin this example by considering a geocoded table in an Access .mdb file.

The illustration above shows our table in Microsoft Access. The table is called Waypoints and is saved in an Access .mdb file called waypoints.mdb. There are three fields in this table, called Waypoint, Latitude and Longitude. The table represents a list of GPS waypoints that were measured with a Garmin GPS receiver.

The three fields in this Access table are all text fields. Each waypoint has a name given in the waypoint field. In this example each waypoint has a number for a name, but there is no reason that the text values in the waypoint field could not have been something like "Position A", "Position B", "Bridge", "Buoy 13", "North East Oil Well" or any other string value. In this example they are simply "1", "2" and so on.

For the sake of this example, it doesn't matter how we got the GPS waypoints into a table in Access. Perhaps we entered them into Access by hand while looking at the GPS receiver's readout, or perhaps we downloaded them using software, such as some freeware GPS waypoint download package. The point is that now we have a geocoded Access table that we would like to use in a Manifold map.

Step 1: Launch Manifold and create a new project

Use File - New to create a new project.
**Step 2: Import the waypoints.mdb table**

Use **File - Import - Table** to import the table into the project.

In the **Import** dialog we choose .mdb files in the **Files of type:** box and choose the **waypoints.mdb** database to open. Press **Open**.
The secondary import dialog will show a list of tables that are available in the database. There is only one table in this database file, so we choose the **Waypoints** table and press **OK**.

A new table, called **Waypoints**, will appear in our project pane as a result of the import process. Moving the mouse cursor over the table will show a Windows tooltip that indicates what type of table it is. In this case, we see that it is a **Local** table, that is, it is a table that is stored within the project file and is not linked from some external file or data source.

If we are curious as to what this table contains, we can double-click on this table to open it in a table window.

If we double-click open the table we can see that it contains the fields and records imported from the Access table.

**Note:** The above procedure imports the table into the project. If desired, we could have linked the table into the project by using **File - Link - Table** to link an external table into the project.

**Step 3: Copy the table and Paste As a drawing**

Click on the project pane to move the focus there, and click on the **Waypoints** table to highlight it if it is not already highlighted.

Choose **Edit - Copy** to copy the table to the Windows clipboard, or (as illustrated above) **Right Click** onto the table and choose **Copy** in the context menu. Experienced Windows users will know they can click on the table to highlight it and then choose **CTRL-C** as the Windows keyboard shortcut for **Copy**.
Click on any empty location in the project pane and...

... choose Edit - Paste As - Drawing to paste the table as a drawing.

The Paste As Drawing dialog will appear to ask us which fields we would like to paste from the table, and which fields should be used for the latitude and longitude coordinates. If we have fields in our table that are called "Latitude" and "Longitude," Manifold will make the reasonable guess that these are the fields we wish to use for coordinates and will, for our convenience, pre-load the combo boxes with those choices. If we would like to use other fields, all fields in the table will be available in the choice boxes as well.

A note for experts: unchecking the Latitude / longitude coordinates box will set the coordinate system to the default Orthographic projection. This is the starting point when the X and Y coordinates represent something other than ordinary latitude and longitude coordinates: the drawing is created in Orthographic and then we can assign whatever coordinate system (such as some State Plane projection...) we like.

The Skip zero latitude / longitude records option tells Manifold to skip any records that have empty values for latitude and longitude. Sometimes we will use tables that include erroneous or incomplete records that don't have latitude and longitude values. This might arise, for example, if we have a table of geocoded street addresses where some addresses were not found by the geocoder and thus do not have latitude and longitude values.

In this example, we have checked only the Waypoint field because we don't wish to also import the latitudes and longitudes for each waypoint as data attributes. Manifold will automatically use the latitude and longitude fields to
place each resulting point: we only need check these fields if we also want to have a written copy of them in the drawing’s table’s attributes.

The result of the *Edit - Paste As - Drawing* operation is a new drawing in the project together with its associated table. By default, since there is already a component in the project called *Waypoints* Manifold takes the name of the table that was pasted and appends “2” to create names like *Waypoints 2*. These names can be changed, of course, to something else if desired by right clicking on the drawing and choosing *Rename*.

We can double-click open *Waypoints 2* to see how our new drawing looks.

The new drawing shows our waypoints plotted as points in a drawing. The position of each point is given by the latitude and longitude fields for the corresponding record in the table that was pasted.

If we like, we can also double-click open the *Waypoints 2 Table* associated with the drawing to see what data fields are in the table.

The table has an **ID** as well as the **Waypoint** field we checked in the *Paste As* dialog. Every object in a Manifold drawing has a unique object **ID** field that is the key field used to link rows in the table to objects in the drawing. If we do not wish to see this field we can always *Hide* it in the table.

**Step 4: Create a Map**
To create a map using the points drawing we would most likely import another drawing or two to provide a "base map" drawing that shows the geographic context of the points. Otherwise, if we just look at the drawing of points we don't know where it is located.

In this example, we have imported a drawing, called `bay_land_eg`, which shows the San Francisco Bay region as areas. This drawing is on the Manifold CD.

To create a map that contains `bay_land_eg` and the `Waypoints 2` drawings as layers we right click anywhere in an empty location in the project pane and choose Create - Map. In the Create Map dialog we see all of the components in the project from which we can create a map, only two such components in this case. We check both of them to be used and move the `Waypoints 2` drawing to the top position. For lack of any deeper inspiration we will call this new map component `Map`. Press OK.

The result is a new map component in the project. We can double click it open to see how it looks.
If we click open Map we can see that the GPS waypoints in our geocoded table are various locations in the Southern part of San Francisco Bay. We have taken a moment to change the background color of the points in the Waypoints 2 drawing from gray to yellow.

However, for a more visually appealing presentation we can click on the Bay_land_eg Drawing layer and change the color of the land areas to green. We can then choose View - Properties for the map and change the background color of the map to a custom background color, a shade of blue. That's better!

**Comments**

This same process as used above can be used to display any geocoded table as a drawing of points. The example used a table of GPS waypoints, but it could have just as easily been any other geocoded table. For example, we could copy a table that listed radio stations by call sign and the locations of their antennas in latitude and longitude and paste it into a drawing with points at the location of each antenna.

This very simple example had no fields except for the name of the waypoint and the latitude and longitude. We could have pasted many more fields if they were present in the table. For example, if we had a geocoded table of cities where each city had a name, population, country name or other fields in addition to the latitude and longitude fields we could have pasted such a table as a drawing. The table created for that drawing would include whatever fields we checked in the Paste As dialog during the Paste As operation.

If the geocoded table does not have latitudes and longitudes in the form shown above it is not yet geocoded. Many different formats are used to write down latitudes and longitudes. For example, on occasion one might encounter the coordinates of waypoint 1 above in the form N 37 41.750 W 122 20.380, which is intended to mean North 37 degrees and 41.750 minutes latitude and West 122 degrees 20.380 longitude. If such coordinates
appear for each record it is not yet geocoded. These coordinates must be converted into standard decimal degrees before the table can be used as a geocoded table.

**Tech tip:** Although it is true that Manifold will attempt to understand coordinate values (that is, latitude and longitude values) written in degrees, minutes and seconds notation when pasting a geocoded table as a drawing, as a practical matter due to the wide variation of styles for writing coordinates in such notation (some such styles being utterly unfathomable to humans, let alone to computers) it is wise to first convert latitudes and longitudes into decimal degrees notation, to be sure Manifold can understand. This documentation is therefore written to require decimal degrees notation. If someone disregards that advice and Manifold manages to make sense of the degrees, minutes and seconds notation they are using, that should be regarded as unexpected good luck.

**Changing Ordinary Fields in a Drawing's Table does not Move Objects**

Recall that there are two ways of creating drawings from geocoded tables: one method is shown in this example, to copy the table and paste as a drawing. This creates an independent drawing that has no connection with the table. The second way of creating a drawing is to link the drawing to an external, geocoded table.

In either case, the drawing is created with a table of its own that hosts whatever data attributes are associated with the drawing. When pasting a drawing from a table, we may choose to include latitude and longitude fields from the table. It is important to understand that such latitude/longitude values that occur as data attributes in the drawing’s table **cannot** be used to "move" points. They are simply additional copies in written form of the data that was used to create the drawing and are not the controls that define the drawing.

The positions of objects in drawings are embedded within the geometry of the drawing. They are an intrinsic, built-in part of the drawing that are not listed in the drawing's table except in the form of normally-hidden intrinsic fields in the table. If the drawing has been pasted from a table, the moment the drawing was created the coordinates for each point in the drawing were taken from the table and embedded into the geometry of the drawing and stored within the drawing component. Even if the drawing's table were empty, that geometry would still be inside the drawing. If the drawing is a linked drawing, the geometry is dynamically updated on the fly deep inside Manifold from the table to which the drawing is linked. In either case, the drawing "knows" where the points are located even if there are no coordinate fields (like latitude and longitude) in the drawing's table.

Sometimes we create drawings from geocoded tables that have a latitude and longitude for each record. We might wish to have the latitudes and longitudes that were used to position the points immediately at hand in the drawing's table, perhaps as a handy, human-readable reference of where each point is located. To do so, when pasting the geocoded table as a drawing we may tell Manifold to bring along the latitude and longitude fields along with the other fields, making a copy of the latitude and longitude values to put into the drawing's table.

Whatever the motive or process that was used to create a drawing, it is often the case that "latitude" and "longitude" numbers will be copied to fields in a table as well as being embedded within the geometry of a drawing. GIS beginners often mistakenly think that the positions of items in the drawing are determined from the listings of latitude or longitude fields in the table, so that editing these fields will move the objects. That's not the case.

The position of points in a drawing are determined entirely and exclusively by the geometry information that is embedded within the drawing. Whether the drawing's table has any latitude or longitude fields at all, or whether such values are changed will have no effect on the position of the objects in the drawing.

It is possible to use normally hidden fields inside the table to see the geometry of objects in human-readable form. Manifold has many cool capabilities and one of them is the ability to reach inside a drawing via that drawing's table and to show in human-readable form the geometry of objects. The intrinsic fields in a table display the actual latitudes and longitudes of objects associated with records. However, intrinsic fields are special, system-generated fields and are different than "latitude" and "longitude" fields we might bring into a table that are ordinary text or numeric fields. The rest of this topic explains why this is so.

Drawings are often created in Manifold from geocoded tables. A geocoded table is a table where each record has latitude and longitude fields that specify the location of that record.

Suppose we have an Access database that contains a list of towns together with their latitude and longitude coordinates:
We can import this Access table into a table in Manifold [either by importing the data or by linking to the external table]:

To create a drawing from this table we use Edit - Copy to copy the table and then we use Edit - Paste As - Drawing in the project pane to create a new drawing based on the data in the table.

If our table was called Towns, by default the new drawing will be called Towns 2 and the drawing's table will be called Towns 2 Table. Each geocoded record will appear as a point in the drawing.
We can combine this new drawing in a map together with a base map of the United States to see at a glance where the various points are located.

When we use the Edit - Paste As - Drawing command to create a new drawing, Manifold will automatically create the associated table for that drawing. By default, that new table will have at least one field, the object ID field. During the Paste As operation Manifold will give us the option of copying additional fields from the original table into the new data attribute table for the drawing. The dialog presents a list of check boxes for each field in the original table. We can copy any of the fields we desire.

For example, if our geocoded table is a list of customer records containing fields such as name, address, city, state, and so forth together with a latitude and longitude for each record, we might wish to copy the name, address and other informational fields. There is no particular technical reason to copy the latitude and longitude fields (these fields in the original table will be used automatically to position the points in the drawing for each record) but we can do so if for some reason we want to have this information in the table.

If we do copy the latitude and longitude fields into a table associated with the drawing, we will see them in the table window when the table is opened. It is very important to realize that these are just table fields that were copied from the original table. They are not a “handle” into the geometric coordinates that define the position of the points within the drawing’s internal structure. Altering the values will not move the points, nor are the fields even necessary to keep the points “positioned” at the right spots.

</table>

If we checked the latitude and longitude fields to be included in the drawing’s table when we pasted the drawing, they will appear in the drawing’s table as seen above. But these latitudes and longitudes are just copies of the data that was used to create the drawing. They do not define the drawing.
For example, in the Table window we could delete the entire "Longitude" column, and the points in the drawing will still be there.

We could delete the "Latitude" field as well. If we do so the points do not magically disappear from the drawing. They will still be there. All that we have done is delete a column from the table associated with the drawing. The points in the drawing have already been created when Manifold read the original database. Changing the text data in the table (either the original one or the new table created with the drawing) changes nothing about those points and does not alter the coordinate numbers inside the drawing.

The above discussion may seem obvious to experienced GIS users; however, for new users it is easy to look at a table full of records with latitude and longitudes and to forget that changing the values in the table does not actually move the points about.

Changing the Location of Points

How then can we change the actual location of points? There are three main ways:

- We can show the (normally hidden) Latitude (I) and Longitude (I) intrinsic fields and then change their values. See Editing Intrinsic Fields in Tables. This is the best method when points must be moved to given coordinates.
- We can right click on individual points in the drawing and use the Object - Coordinates dialog to change the location of the geometric coordinates that define the points. This is a seriously tedious approach.
- We can use any one of a wide variety of interactive editing tools in a map or drawing window to move the points by selecting them and dragging them to a new location.

Note that none of the above options will change the contents of any "latitude" or "longitude" text fields we might
see in a table window. For example if we click and drag a point to a new position using an editing capability that will not change the values of any fields other than the intrinsic fields.

Notes

In this example we created a table using Access. We did this deliberately to show how a geocoded table might look in an application outside of Manifold and then how it is imported into Manifold and used within Manifold.

Some times users who are new to Manifold may think from the use of Access in various examples that Manifold somehow requires the use of Access or is somehow tied to the use of Access .mdb files. That is not the case. Manifold does not need any other DBMS software to function, nor does Manifold require the use of Access or Access .mdb files.

For that matter, we don’t need Access or any other DBMS to create tables in Manifold. We can create tables entirely within Manifold as is set forth in the Create a Table and Add Records example. Manifold includes a built-in database engine of tremendous power and sophistication to facilitate the creation, editing and use of tables, either as standalone tables or as tables that belong to drawings. In addition to that built-in capability, Manifold can also work with virtually any DBMS system or database file format.

This example began with an Access .mdb file because quite often we might encounter geocoded tables in that format. We could have just as easily begun with an Excel .xls file or have given an example using a table from SQL Server or from an Oracle database.

Important Note when Using 64-bit Manifold Editions

Due to a lack of required Microsoft facilities in 64-bit Windows systems, Manifold in 64-bit mode cannot export, import, export or link to DB, HTML, MDB, XLS or WKx format files. This includes no access to the MDB parts of Manifold MFD and MapInfo TAB imports. The workaround for importing or exporting such files is to launch Manifold in 32-bit mode by using the Manifold System (32-bit) shortcut, perform the export from or import into a .map project file and then re-launch Manifold in 64-bit mode using the Manifold System (64-bit) shortcut. Linking is more complex: the data must be in some format usable in 64-bit mode within 64-bit Windows systems, such as a SQL Server database. Alternatively, the data can be kept within a Manifold .map project file and linked using the Manifold ODBC driver.
Create a Geocoded Table from a Map

The previous example showed how to create a drawing from a geocoded table. Sometimes we have a map of points and would like to create a geocoded table from that map.

Important: If you have installed 64-bit Manifold, do this example in 32-bit mode by launching Manifold System using the Manifold System (32-bit) shortcut. See the note on 64-bit Manifold at the end of this topic.

For example, one of the most frequent requests in GIS newsgroups is to get a list of cities with the latitude and longitude of each city together with some data for each city, such as the name, population or other fields. It is often the case that we can acquire a digital map that shows the locations of points such as cities but which does not have the latitude and longitude of each point explicitly set forth in the data attributes. Manifold allows us to use that map to create a geocoded table.

In Manifold, we can create tables that include the latitude and longitude of each point in a drawing by simply copying the drawing and pasting it as a table. This example uses a drawing that shows cities in Europe; however, the same method can be used to create a table with latitude and longitude coordinates (a geocoded table) for any set of points in a drawing. The points could be oil wells, obstructions in a nautical chart, the location of campsites or any other point data.

Step 1: Create a project

Open a new, blank project and import the Europe_eg.mif drawing from MapInfo .mid/.mif format and the Ecities.mfd drawing from Manifold 4.50 .mfd format. Create a map using the Europe_eg drawing, open the map and then drag and drop the Ecities drawing into the map. Format it as shown below.

In this example our project contains two drawings: Europe_eg, a drawing of Europe, and Ecities, a drawing that contains a series of points. A map (called “Cities in Europe” in a stroke of literary inventiveness) shows the two drawings together.

If we click open the map we can see the cities shown as yellow dots on the European background drawing.
The cities drawing by itself is just a drawing that contains points.

If we click open the **Cities Table** table associated with the **Cities** drawing we can see there is one data field, **Place_name**, in the table that gives the name of the city. Note that there are no latitude or longitude fields in the table. [The ID object ID data field that is part of every record associated with an object in a Manifold drawing table has been hidden to keep the table illustrations less cluttered.]

**Step 2: Copy the drawing**

To create a geocoded table we begin by copying the drawing.

Right click on the **Cities** drawing in the project pane and choose **Copy** to copy the drawing.

**Step 3: Paste the drawing as a table**

Next, right click onto any blank location in the project pane and choose **Paste As - Table**.
The Paste As dialog appears to ask which fields we would like to paste into the table for each record. We will scroll down and check the Place_name, [Longitude (I)] and [Latitude (I)] fields. Fields with (I) in their name are intrinsic fields that are automatically computed by Manifold based on the geometry of the objects in the drawing.

There are several options for computed fields that are designed for use when pasting areas or lines as geocoded records. With points we simply choose the [Longitude (I)] and [Latitude (I)] fields.

The result is a new table in the project called Ecities 2 that is not bound to any drawing.

If we click open this table we can see that in addition to the Place_name field it also has Longitude and Latitude fields for each record.

**Step 4: Export the new table**

If desired, we can export the Ecities 2 table to any database format supported by Manifold. To do so we click open the table and then choose File - Export - Table to export it to the desired database format. For example, we could save it as a Microsoft Access database file by exporting it to a .mdb file.

**Notes**
The Manifold CD contains a file called `ecities.mfd` in Manifold 4.50 format that is similar to the `Ecities` file used in this example. The difference is that the version on the CD already has explicit `Latitude` and `Longitude` fields for each city in the drawing's table. If you would like to use the version on CD to follow along with this example, after importing the `Ecities` drawing, open the drawing's table and delete the `Latitude` and `Longitude` columns.

**Important Note when Using 64-bit Manifold Editions**

Due to a lack of required Microsoft facilities in 64-bit Windows systems, Manifold in 64-bit mode cannot export, import, export or link to DB, HTML, MDB, XLS or WKx format files. This includes no access to the MDB parts of Manifold MFD and MapInfo TAB imports. The workaround for importing or exporting such files is to launch Manifold in 32-bit mode by using the Manifold System (32-bit) shortcut, perform the export from or import into a .map project file and then re-launch Manifold in 64-bit mode using the Manifold System (64-bit) shortcut. Linking is more complex: the data must be in some format usable in 64-bit mode within 64-bit Windows systems, such as a SQL Server database. Alternatively, the data can be kept within a Manifold .map project file and linked using the Manifold ODBC driver.
Create a Linked Drawing from a Geocoded Table

In this example we create a linked drawing from a geocoded table created in Microsoft Access. Before beginning this topic, please read the Creating Drawings from Geocoded Tables topic.

Important: If you have installed 64-bit Manifold, do this example in 32-bit mode by launching Manifold System using the Manifold System (32-bit) shortcut. See the note on 64-bit Manifold at the end of this topic.

There are two ways of creating drawings from geocoded tables. A simple, straightforward way is to copy the table and paste it as a drawing. When the drawing is created the coordinates for points in the drawing and their data attributes (if specified for transfer) will be copied from the table. The created drawing (and its table) will be new components that are completely independent from the table that was copied. This process is shown in the Create a Map from a Geocoded Table topic.

Another way of creating a drawing from a geocoded table is to link the drawing from a geocoded table, which may be within the project or which may be some external geocoded table. In this case every time the linked drawing is opened or refreshed it will be dynamically recreated on the fly based on the data in the geocoded table. The position of points and their data attributes will be dynamically taken from the geocoded table. If the geocoded table is altered to add, delete or change the coordinates of records then when the drawing is refreshed the points in the drawing will appear, disappear or move as the table records are updated. This topic shows an example of this process using a geocoded table in an external Access .mdb file.

The distinction between the above two scenarios is subtle, but important. In the first case the data from a table are copied and a new, independent drawing is created. In the second case, a "virtual" drawing is created that remains linked to the table and is controlled by it.

If we have been working through the examples in order we have seen use of import and linking dialogs using simple file types.

In such dialogs the Files of type choice acts as a filter for what is displayed in the browse pane in the File - Import or File - Link dialogs. Simple file types are imported directly from the Import dialog by choosing the desired type in the Files of type box. More complex imports from data sources such as databases are imported by choosing Data Sources ( ) in the Files of type box and then using the Data Source dialog.

Using the File - Link - Drawing dialog takes us into more advanced territory, because whenever we link a file the Data Source dialog is always used to make the connection, even if we would like to link to a simple file type such as Access .mdb.

The reason for this is that a linked drawing is normally a bidirectional, live connection between the linked drawing within Manifold and the originating data source. It is not a simple matter of reading some file, importing the data into Manifold and then forgetting about the original file. Linking a drawing means that Manifold must do all possible to propagate any changes made within the Manifold product back into the originating data source. That normally requires more complicated machinery within Manifold and to maintain modularity within Manifold's internal programmatic structures a more sophisticated access method, the Data Source dialog, is used in all cases of linked drawings.

**Step 1: Create a table in Access**
We begin by launching Microsoft Access and creating a geocoded table called **Towns** in the Access database. The table shows various towns in the United States together with a latitude and longitude location for each town given in decimal degrees. It also includes a URL for the official website for each town and a size field giving the relative population of each town. The fields are all text fields except for the size field which is a number. We save the Access database as a file called **towns.mdb**.

Although Access is a fairly simple DBMS it can be used for multi-user work. More than one program at the same time can use a .mdb database file. In this example we will use the **towns.mdb** database file within Access and at the same time we will use it within a Manifold session by linking to it from Manifold.

**Step 2: Create a linked drawing in Manifold**

Keep the Access session running with the **Towns** table open. Launch Manifold and create a new project. Choose **File - Link - Drawing** to link a drawing into Manifold using a DBMS table.
That launches the Data Source dialog to allow us to choose a data source. This dialog lists previously-created data sources. On the system used for this example there are some spatial DBMS data sources created but not yet one for the file containing the *Towns* table. We’ll create a new data source by pressing the **Add Data Source** button.

![Connect To dialog](image1)

That launches the *Connect To* dialog (very similar to the standard Windows *File - Open* dialog). We choose **MDB Files** in the **Files of type** box and then browse over to the *towns.mdb* file and click **Open**.

![Data Source dialog](image2)

That launches the *Data Source* dialog. We enter *Towns mdb file* for the **Name** and type in the directory path to the *data*townsmdb file and click **OK**.
This creates a new data source in the Data Source dialog, initially named something forgettable like OLE DB Data Source. We immediately rename it to something we will remember, Towns mdb file. We can then double-click the new data source to use it.

This gets us to where we want to go, a Link Drawing dialog. This dialog allows us to choose which table in the .mdb file we want to use to control the drawing and which fields we would like to include in the drawing's table. This is a geocoded table (latitude and longitude values for each record), so the Type is Table with coordinate columns.

We choose the Towns table and choose all columns for import. We use the Longitude and Latitude fields for the coordinates. [Advanced users will be interested to learn that it is possible to choose a query from the database file (if one exists in it) and not just a table. Queries provide a set of records just like a table does and can be used to control a linked drawing just like a table. The only limitation is that parameter queries cannot be used since there is no way to interactively provide a parameter to such queries.]

The dialog also includes a Line ID box that allows us to choose a field that can be used to create lines in the drawing. We will not choose a field since for this example we will only create points. See the Linked Drawings from Geocoded Tables topic for information on creating lines in linked drawings.

Press OK and the result is that four new components appear in the project: a new linked table called Towns, a query called Towns Points and a linked drawing called Towns Points Drawing and the linked drawing's table. Note that the linked components are shown with icons that include a yellow "database" cylinder to indicate they are created from a database.
This is a classic example of a linked drawing created from a geocoded table. Manifold first links a table within the project to the external table, and then creates an intermediate query that transforms the coordinate column data (that is, the data in the latitude and longitude columns) into geometry form so that a linked drawing can be created from that query.

If we open **Towns Points Drawing** we see it contains points, as might be expected from the default name given this drawing by Manifold. In the screenshot shown above we've taken a moment to format the points in a bright green color and to increase their size slightly.

Each point is automatically created from one of the records in the .mdb table, with the data for each point coming from the .mdb table into the linked table in the project, through the intermediate query and then finally into the linked drawing and the linked drawing's table.

If we open the drawing's table we can see that the data attributes for each point are taken from the originating .mdb table as well. All fields appear in this table because we selected all of the .mdb table's columns in the **Link MDB File** dialog. Note that the fields in this table maintain a "live" connection back to the originating external database table. If we change a value in this table the corresponding value in the external .mdb table will change as well.

**Step 3: Show the drawing in a map**

We can import the **US_main** basemap drawing from the Manifold CD, create a map using it and then drag and drop the **Towns** drawing into the map as a layer.
The map shows us that the towns are, in fact, located in the correct geographic locations. To show a more elegant illustration we’ve also taken a moment to specify the projection for the map as an Orthographic projection.

**Step 4: Alter the Access table and see points move**

The useful thing about linked drawings is that if the external database table changes in Access then the linked drawing in Manifold that is created from the table also changes. We can see this by editing the table in Access even as we leave Manifold running.

Using the Windows taskbar we switch back to the Access session.

In Access, let's change the longitude value for Palo Alto.

We'll change it to **-132.15** and then press the pencil icon to make the edit take effect.
The Access table has now been changed. Since Access instantly propagates all changes to the .mdb file in use, the towns.mdb file used to control the linked drawing in Manifold has also changed.

Using the Windows taskbar we switch back to the Manifold session. We click on the map window that displays our drawing and we refresh it to update it with any changes.

In Manifold, we choose View - Refresh Data to make sure that the map in Manifold is updated. When working with Manifold as a desktop application we refresh linked components to see changes. When using Manifold as an Internet map server, the refresh time can be automatically controlled to refresh every given number of minutes or on every image served.

[The Autorefresh View setting seen in the illustration above is used to control windows for things like updating red selection color when items are selected. It does not relate to data refresh as used with linked components.]

After we do a View - Refresh Data command we see the dot for Palo Alto has moved farther West into the Pacific Ocean. As the longitude changed in the .mdb table the point moved to the new location. Any changes made to the external table will appear in the linked drawing as soon as it is refreshed. If a record is added to the external table a new point will appear in the drawing. If a record is deleted from the external table the record's point will be deleted from the drawing.
The creation of linked drawings from external tables is extremely useful, because it allows the use of generic external tables as a data exchange interface for our GIS applications. There are many applications in which the locations of items of interest are captured within a geocoded table. For example, we might have some third party software that monitors the output of GPS transmitters in trucks and updates the location of each truck within a database table, or we might have a table from a web service that publishes the locations of recent earthquakes, the locations of ocean buoys, or the locations of lightning strikes.

There are many more programmers who know how to write code for DBMS manipulation than know GIS, and so as a result there are many more applications that know how to place locations of interest into some sort of geocoded table than know how to interface with any particular GIS package, or, for that matter, with Manifold. The use of linked drawings allows Manifold to interface with such applications without the application needing to know anything about Manifold. The application continues to write locations into the database table as it has long been accustomed to doing. Manifold automatically grabs the data from that table and updates the linked drawing created from it.

In this case, the database system in use is not just a convenient, centralized data warehouse for our organization - it also functions as a "firewall" of sorts between the knowledge needed to get information into the database and the knowledge needed to do something with that information in Manifold.

**Step 5: Thematically format the drawing**

We can use the data fields in the drawing's table just as we would any drawing's table. For example, we can use them to thematically format the linked drawing.

We could format the size of the points and their colors based on the size data field in the drawing's table. As the size field changes in the .mdb file the points will automatically change their size and their colors accordingly. This is a very useful way of presenting varying data in an IMS-driven website.

Note also that double-clicking on a point will launch the hyperlink in the URL field, which is also taken from the table that controls the linked drawing. In sophisticated IMS web sites we can use linked drawings to display information from tables that are changed by other Internet processes. For example, a table might be edited to update the contents of URL fields for each record based on the results of other programs.

**Step 6: Propagating Changes back to the Access Database**

Now, let's do something that usually proves endlessly confusing to beginners. We will edit the longitude and latitude values in the drawing's table and make the corresponding point move in the drawing. But, according to the Tech Tip discussion in the introductory Creating Drawings from Geocoded Tables topic this is not supposed to be possible, true? Let's see for ourselves:
We open the linked drawing’s table and note that, as expected, after we changed the Longitude value for Palo Alto to -132.15 it not only moved the point in the linked drawing but it also changed the corresponding data value in the drawing’s table, which was copied from the Access .mdb table.

We double-click into the cell to edit it...
...and we change the value back to the original value of \(-122.15\).
When we changed the Longitude value for Palo Alto in the linked drawing's table, because of the "live" connection between the linked drawing and its origin, that change was propagated backwards through the linked table back into the Access table, where the value was also changed to 122.15.

![Diagram of cascading links]

We can diagram what happened as shown above. It is not that the change in the longitude cell in the linked drawing's table move through some sort of hard-wired connection from the table directly to change that table's drawing. Instead, what happened is that the change in the linked drawing's table changed the value in the Access table (blue arrow).

When the linked drawing was refreshed, the change in the Access .mdb table was updated into the Towns linked table in the Manifold project and the change in that linked table was propagated through the Towns Points intermediate query into the geometry information used to build the Towns Points Drawing linked drawing.

Linked drawings in this case are different from standalone drawings. Changing the data fields in a standalone drawing's table won't result in any changes in the drawing, since those fields are not linked to anything and are just copies of the data used originally to create the drawing. But with a linked drawing, that linked drawing's table maintains a dynamic link back to the originating table, so changing the fields in the linked drawing's table in a roundabout way comes back to influence the geometric structure of the linked drawing.

This is a bit tricky and sophisticated for beginners, but it is nonetheless a good illustration of how cascading links work within Manifold and how such cascading relationships are preserved even though the data types within each link may be different. We can exploit these capabilities to build IMS sites and other useful applications.

For example, suppose we would like to build an IMS site that allows people to add and move points by editing their latitude and longitude values. A simple way of doing this is to use a linked drawing that takes its data from a geocoded table. Without needing the relatively more sophisticated ability to edit internal drawing geometry we can simply allow users to edit fields in database tables, a task usually well within the skill set of most web developers, who tend to have greater experience with the manipulation of database tables through web sites than they do with the programming details of working with a specific GIS package such as Manifold.

Important Note when Using 64-bit Manifold Editions

Due to a lack of required Microsoft facilities in 64-bit Windows systems, Manifold in 64-bit mode cannot export, import, export or link to DB, HTML, MDB, XLS or WKx format files. This includes no access to the MDB parts of Manifold MFD and MapInfo TAB imports. The workaround for importing or exporting such files is to launch Manifold in 32-bit mode by using the Manifold System (32-bit) shortcut, perform the export from or import into a .map project file and then re-launch Manifold in 64-bit mode using the Manifold System (64-bit) shortcut.

Linking is more complex: the data must be in some format usable in 64-bit mode within 64-bit Windows systems, such as a SQL Server database. Alternatively, the data can be kept within a Manifold .map project file and linked using the Manifold ODBC driver.

Formatting Lines in a Linked Drawing
Formatting Lines in a Linked Drawing

This example shows how to create lines in a linked drawing and then how to format those lines using information stored in an external table. The form of linked drawing used is a limited one normally used only for the display of points from geocoded tables. A more sophisticated form of linked drawings stores line objects in databases uses geometry in tables in a much more powerful way that does not encounter the key issues explored in this example.

However, it is often the case that the only data available to us is not in sophisticated form stored as geometry in databases but instead comes to us in the form of relatively primitive geocoded tables. This topic shows how to use such data. It also embraces the added complexity of leveraging such data to show line objects as an opportunity to teach more advanced notions of how queries can create drawings.

In this example we simulate an application where we have a geocoded table that shows ship tracks, and we have another table in our database that shows information about each ship. We use the two tables together to format the lines that show the ship tracks.

The geocoded table used is similar to the example set of data illustrated in the Linked Drawings from Geocoded Tables topic. Please read that topic before continuing with this example.

Step 1: Create Linked Drawing

We will create a linked drawing from a simple geocoded table. The table is in a comma-separated value format in an ordinary text file called Ship tracks.txt.

If we open the Ship tracks.txt file in notepad we can see it is similar to the tabular data used in the Linked Drawings from Geocoded Tables topic for simple illustrations.

To create a linked drawing, we choose File - Link - Drawing to launch the Data Source dialog and then we add a new data source to the dialog using the same procedure as used in the Create a Linked Drawing from a Geocoded Table example topic. In the Connect To dialog we open the Ship tracks.txt file using a Files of type setting for CSV (comma separated values) text format.
We use the settings shown above in the Link Drawing dialog. Note that the LineID field is used for the Line ID option and the Order field is used for the Coordinate order option.

The result is that seven new components are created in the project pane. The Ship Tracks table is a new linked table that is linked to the external text file. It brings the data from the external file into the Manifold project.

Two new queries, Ship tracks Lines and Ship tracks Points, are also created. Their job is to take the coordinate column information from the linked Ship tracks table and to convert it into geometry form so that it can be used to create drawings. The queries also bring along whatever columns have been requested in the Link CSV File dialog. The Ship tracks Lines query extracts geometry information for lines and the Ship tracks Points query extracts geometry information for points.

Finally, two new linked drawings (and their tables) have also been created. One drawing is created from the geometry information for lines and the other is created from the geometry information for points (Manifold will create a point object for each record in the geocoded database regardless of whether the record is involved in a line or a point).

Open each of the created drawings and confirm its projection by using the Edit - Assign Projection dialog.
**Step 2: Create a Map**

To see the lines drawing together with the points drawing we can create a map.

Pull down the **Create** menu in the project pane toolbar and choose **Map**.

We check both the lines drawing and the points drawing. Since it is usually better style to show points above lines, we will click on the points drawing entry and move it to the top of the stack.
This will show the points drawing as a layer in the map above the lines drawing layer. Press **OK**.

This creates a new map component in the project.

We can click the map open to see that it shows the two drawings as layers with the points drawing above the lines drawing. We confirm the projection of each drawing by clicking on the info bar and clicking **OK** in the **Assign Projection** dialog. After that, we click on the lines drawing layer tab and format the drawing so that lines have a thickness of **3**.
If we open the line drawing’s table we can see that line objects have been created in addition to the point objects, using the LineID field to guide the creation of the line objects. The lines have inherited the LineID values from the points used to create them. Note that the table’s ID column is shaded because it is read-only.

We cannot modify the contents of columns in a linked drawing's table if the drawing is linked from a query and the records returned by the query do not correspond in one-to-one fashion to records in some physical data source, such as a table. In this case, there is not a one-to-one correspondence because the line objects have been created from multiple records in the original table.

Note that a second effect of not having a one-to-one correspondence between line objects and the various points from which they are created is that there is no guaranteed method by default to say what fields or field values, if any, those line objects should inherit from the many points aggregated into each line.

To see why this is the case, consider a line that is created from five points. It is possible that all five points might have exactly the same fields and exactly the same values in those fields. In such a case we may think, “OK, let's have the line created from those points have the same fields and the same values in those fields as well.” But it is not at all guaranteed that such a happy coincidence will occur in all cases. In the case of points representing ship track locations, for example, the time the data for that point was measured, the bearing of the ship at that moment and the sea water temperature and salinity at that location. How should those values, by default, be aggregated into a line object created from such points?

If we were working exclusively with tables within a Manifold project we could have Transfer Rules assigned to say how the "many to one" aggregation should take place, but there are no such things as transfer rules within ordinary text files like the one from which we drew the data, or within plain, ordinary database files of various kinds from which simple geocoding data of this nature is usually sourced. Therefore, the query that is built in such cases to aggregate lines from points simply creates line drawings and can not guess at what is intended.

The ideal, long term solution for aggregating data points into line objects is to use a more sophisticated data storage medium than text file tables. For example, we could use a real database capable of storing geometry in tables such as Oracle spatial or similar, and we could use sensible procedures for building line objects within that database at the time the data is acquired. Drawings could then be linked from such databases and the lines and data attributes for those lines would be created exactly as stored within the data source with no guesswork or manual intervention required.

The pragmatic, short term solution to dealing with such aggregation is to decide what we want out of the data that we have on hand, primitive though it may be, and to make adjustments in the default queries in our Manifold project so that we can have our way with the data as we'd like. This example shows us how.

**Step 3: Create and Link a Table**

For the purpose of this example, let's pretend that these lines represent the tracks of ships. We would like to format the lines based upon an external table.
We launch Microsoft Access and create the **ShipData** table seen above and then save the Access database in a file called **Ship Data.mdb**. There's no particular reason why we used Access to create the table or why we saved it in an **.mdb** file. However, using Access and an **.mdb** file makes the point for the purpose of this example that we can use external programs and external databases to control things within Manifold. We could have, of course, created the table within Manifold and then used **File - Export - Table** to save it to an **.mdb** file, but that would not be as good an example of work outside Manifold.

Using **File - Link - Table** we link a table into our Manifold project using **Ship Data.mdb**. See Importing and Linking Tables for information on how to link a table into a project. If we open the table it appears as shown in the illustration above.

**Step 4: Modify the Query**

So far, so good. We now have a linked drawing that shows points and lines and a linked table that lists some colors and ship names. We need to put the two together using a **Relation** so the colors and ship names appear in the drawing's table.

Before we establish a relation, we need to bring the **LineID** column into the lines drawing. To do that, we modify the **Ship tracks Lines** query to include the **LineID** column.

This is easy to do. We pop open the query, which is shown above. (We've inserted a line break before the **From** statement to allow a more compact screenshot.)
We add a [LineID] column reference as shown by the red arrow above. (The red arrow has been added to the illustration. Manifold does not show red arrows in queries when something new is added.)

We then refresh the drawing by selecting its layer tab and clicking the **View - Refresh Data** command in the main menu. If we open the drawing's table we see that it now has a LineID field brought in from the query from which it is generated, as seen above.

**Step 5: Form a Relation**

Open the drawing's table and launch the Table - Relation command.

Add a new relation that uses the LineID field in both the Ship tracks Lines Drawing Table and the ShipData table as a common field.
Check the **Color** and **ShipName** fields to appear in the relation.

The result is that the drawing’s table will acquire two additional columns, **Color** and **ShipName**, which are taken from the **ShipData** table.

If we pause to think about this for a moment, this is a very interesting situation. This is a relation in a linked drawing, after all, so data in drawing’s table appears in our project as a result of a dynamic linkage to an external table.

We cannot alter the contents of cells in the drawing’s table (which is created by the spatial query that aggregates info from the geocoded table to create lines) but we can add other columns to the table by relations.

The two columns we’ve added are brought in dynamically from a linked table. The linked table appears in our project courtesy of a dynamic linkage to another external table. Everything we see in this table is controlled by two tables that reside outside of Manifold, one table residing in an ordinary text file and the other table residing in an **.mdb** file.

**Step 6: Format the Lines in the Drawing**

Even though the data in the drawing’s table appears dynamically within Manifold as a result of linkages to external tables, we can use the table just as we would any drawing’s table for thematic formatting.
We open the map and click on the Ship tracks Lines Drawing layer to move the focus to the drawing’s layer and then click on the foreground color for lines in the format toolbar and choose Theme to format the lines using a thematic format. We can format the lines by the Color field as seen above.

The result is that the lines are colored red, green, blue or black depending on the value of the Color field.

Again, we have a very interesting situation: the colors of the lines are determined by text fields written into the Ship Data.mdb file that is located outside of Manifold.

**Step 7: Edit the External Table to change Formatting**

Because the colors are taken from an external table, we can change the formatting of by editing the external table.
We can launch Access, open the `Ship Data.mdb` file and change the `Color` value for the first record from `red` to `green`.

Within Manifold, the table that is linked to the `Ship Data.mdb` table also will show a change in the value of `Color` for the first record from `red` to `green`.

If we click on the drawing to give it the focus and then choose `View - Refresh Data` to refresh the drawing's data we see that the ship track in the lower left changes color from red to green.
Refreshing the drawing also refreshes the drawing’s table. We can see that all of the Color values for objects having a LineID value of 1 have changed from red to green.

**Comments**

This example shows how tables outside of Manifold can be used to create points and lines within Manifold and then to format the lines. If we published the above drawing to a Manifold IMS web site, IMS would automatically refresh the drawing for us. We could thus create a web site where other programs could easily write to tables in standard database formats and thus control objects and the appearance of those objects within the maps served by Manifold to the web site.

In this example we had only two data fields, Color and Ship Name, within the external Ship Data table. We did not use the Ship Name field in this example, but it would have been easy enough to create a labels component from this field to show the ship names for each ship track in the drawing.

For that matter, there could be any number of fields in the external table that could be incorporated via a relation within the drawing’s table. We could have fields that provide URLs so that when a line is clicked a hyperlink would be followed to a new web site, perhaps a web site that gives information about a particular ship’s cargo. There are no reasons why external programs could not edit those fields as desired based upon the business logic required for the web site.

We used .txt and .mdb format files for the external tables for no particular reason other than to provide a very simple example that anyone can recreate. While use of .mdb may be fine in a typical web site, in a web site expecting very many visitors it is more likely that the tables used would be hosted on a higher performance database system, such as SQL Server or Oracle.

When recreating this example in an IMS web site, keep in mind the need to make sure the IUSR_login used for the Internet visitor served by IIS has correct access permissions. For example, the IUSR_account must have read permissions for the .map file involved as well as all database files used for linked drawings. If a .mdb file is used, the IUSR_account must also have read and write permissions for the folder in which the .mdb file is located, so that the map server process can create a lock file as is required when working with .mdb.

We used just one field for formatting the color of lines. There’s no reason why other fields could not be used within the external tables to format the points or to format other characteristics such as style or size.

Linked Drawings
Create a Linked Drawing from a Geocoded Table
Storing Drawings in SQL Server

This topic shows how to export drawings into spatial DBMS within SQL Server using Manifold spatial DBMS facilities. We can then link those drawings from the database into our projects and get the benefit of concurrent, multiuser editing. This example requires Enterprise Edition, since storing a drawing into a database using a spatial index for spatial DBMS capability requires Enterprise Edition or higher edition. Once stored in this way, any Manifold edition can import or link the drawing from the database.

The project also shows how to use Administrator Console, a wonderful feature in Database Administrator Edition, to prepare drawings stored on the server for storage of formatting and use of more easily understood friendly names.

This example shows the entire process of uploading a drawing into SQL Server and then linking it into a project. We'll use the SQL Server 2005 Express Edition installation downloaded from Microsoft, so the example assumes we have already installed SQL Server on our computers. Whenever working with SQL Server 2005 (including SQL Server 2005 Express SP 2 or more recent) we should install the Manifold Spatial Extender for SQL Server on the server machine; however, because the Manifold spatial extender is transparent to Manifold functioning (it makes spatial DBMS work with SQL Server 2005 faster and more robust), this example will be identically the same whether we have installed the Manifold spatial extender or not.

The example is written to assume that we are using Manifold on the same machine on which SQL Server has been installed. We can, of course, use a SQL Server installation other than one on the same machine as Manifold and usually will. See the Microsoft documentation for use of OLE DB connections to learn how to set up the dialogs to connect to SQL Server in whatever configuration your installation happens to use.

In Microsoft networks this can be as simple as using the server's name in the connection string instead of (local) for example, if our SQL Server machine's Windows computer name is REDMOND we could connect using REDMOND\SQLEXPRESS instead of using (local)\SQLEXPRESS as cited below.

This assumes, of course, that Windows access permissions and SQL Server have been correctly arranged so that user logins and client machines can connect to and use SQL Server on the server machine. See the SQL Server Express Edition topic for an example of a procedure that enables access to SQL Server from other machines and users in the same domain.

For an example of export to a native spatial DBMS using Oracle, see the Example: Storing a Drawing in Oracle topic.

Step 1: Create a Drawing

The first task is to create a sample drawing we can use to show how to upload drawings in SQL Server. We will do so by importing an existing drawing, since that is significantly faster than drawing a few thousand roads freehand. This also gives us a chance to use this example to show how to import a drawing from the Geocoding Database provided on the Manifold download site.

If we have the optional Geocoding Tools extension installed and have installed the Geocoding Database onto our hard disk, we can import drawings of any county in the United States. To do so, choose File - Import - Drawing and in Import Drawing dialog's Files of type box choose the Geocoding Database Files (states.dat) option.

Navigate to whatever folder holds the Geocoding Database files and double-click on the states.dat file.
The **Import Geocoding Database** dialog opens. Since every Manifold user on the planet is dying to learn more about Carson City, the legendary capital of the state of Nevada, we will use Carson City county in Nevada as the sample county for which we will fetch a drawing. We will also check the **Import Formatting** box so that the drawing appears with default formatting. Press **OK**.

**Note:** Strange as it sounds, there really is a county in Nevada known as “Carson City” even though “City” usually means something explicitly other than “county” in the hierarchical sequence of city-county-state-country. There is such a county name in Nevada because when one has a metropolis of the size of Carson City in the middle of what is otherwise exceptionally bleak, uninhabited terrain the region tends to become known by the name of the sole point of habitation. Carson City is also the state capital of Nevada so no doubt the prestige of such a famous seat of government had a role in the matter of naming the county as well.

Using this particular “county” is slightly misleading within an example topic because some readers will just look at the pictures and not read this text and might therefore believe that this particular importer can fetch drawings for individual cities. That's not the case. It works for county names only and fetches the entire county. It's just that this particular county has a weird, misleading name.

![Carson City NV Drawing](image)

We can open the drawing thus imported and see that it shows the epic scale of Nevada's state capital and surrounding wasteland. Several watercourses are optimistically indicated in blue to show those dry channels in
the desert through which flash floods rage on rare occasions. Contrary to popular belief, it does rain in Nevada, at times strongly enough for water to flow vigorously over the otherwise hard-baked, alkali desert surface.

**Step 2: Save Formatting for Later Use**

We are going to take a moment to save the formatting for this drawing because later on we will need that formatting again.

To do so, click into the foreground color well for lines, choose Theme... and in the Format dialog choose the Save to File command. Save the formatting to a file, perhaps using a name like carson_formatting so it will be easy to remember what that file is for.

**Step 3: Export Drawing to SQL Server**

OK. Enough preliminaries... let's do this. Choose File - Export - Drawing
In the Save as type box we choose Data Sources (). This will launch the Data Source dialog.

The Data Source dialog has not yet had any data sources added to it, so we will click the Add Data Source to add a new data source.

In the resulting Connect To dialog we choose OLE DB Data Sources. Note that we do not use the SQL Server Data Sources option, as that is a special connection used to connect to Microsoft's new SQL Server 2008 spatial (Katmai) spatial DBMS. In this example, we are using Manifold-managed spatial DBMS capabilities within ordinary SQL Server 2005.
This launches the **Data Link Properties** dialog, a standard Microsoft dialog used to connect to OLE DB data sources. In the **Data Link Properties** dialog we choose the **SQL Native Client** and press **Next**.

**Note:** The above assumes we have installed SQL Server Native Client on all client machines so that the SQL Native Client provider is available.
This moves us to the Connection tab, where we enter (local)\SQLEXPRESS for the Data Source. We click the Use Windows NT Integrated security option to log on to the server. This option uses our Windows login status to determine our access to the database. That's usually a more convenient way to set up access to the database (and is the default suggested in the installation topic for SQL Server in this documentation) because most people have trouble enough remembering their Windows login and password let alone a separate user name and password for a database.

Although it is not strictly necessary, we like to press the Test Connection button to see if a connection can be made to SQL Server. It's handy to do that now so that if we made any typographic errors in the Data Source string or if SQL Server is for some strange reason not alive it is best to find that out right now.

When the connection succeeds, a cheerful message box pops open to tell us so. Press OK to close the message box, and then back in the Data Link Properties dialog press OK once more to continue with the export of the table.
Back in the Data Sources dialog we see that a new data source has been added using the default name for the connection. It is usually wise to enter some more memorable name that will help us recognize data sources in a more useful manner. This is easy to do.

In the Name box we can enter the friendly name we would like to use to identify this data source. For this example we will name this data source **Local SQL Server Express**. To use it we either double-click it or we highlight it and press **OK**.
The **Export Drawing** dialog allows us to choose how we will export the drawing, including which columns we would like to export from the drawing's table. Manifold has already helpfully loaded the dialog with reasonable defaults, which we will accept.

We are exporting into a database using Manifold-managed spatial DBMS technology, so the **Type** will be **Manifold**. The pre-built **Geometry** and **Version** columns will be used to convey drawing geometry and make ready for multi-user editing versioning, respectively. The geometry type will be Manifold's native **Geometry** type, the best choice for speed, perfect storage of coordinate system (projection) information and robustness. Manifold will automatically create a spatial index by default.

To store data attributes from the drawing's table we could check or uncheck as many columns as we like. For this example, we will use defaults. We press **OK**.

At this point we have created a drawing and have uploaded it into SQL Server.

**Step 4: Connect to SQL Server with Database Console**

Let us now see how to use within other Manifold projects the drawing uploaded into SQL Server. That drawing will now be available to us whenever we launch Manifold and import or link the drawing from the server.
Suppose it is a few days later and we want to use that drawing. We launch Manifold and choose Tools - Database Console to launch the Database Console.

Database Console remembers the last-used Data source. If we have not previously used Database Console or if we last used some other data source we can instantly get the Local SQL Server Express data source we desire by pressing the [...] browse button to the right of the Data source box in Database Console and choosing Local SQL Server Express in the Data Sources dialog. The Data Sources dialog is extremely useful because once we configure a data source in that dialog it is remembered for future use.

Press the Refresh button to refresh the Database Console display from the Local SQL Server Express data source.
Database console will now light up with a view of our SQL Server database. This particular SQL Server database has been used to store many components. Manifold will helpfully provide drawing, image and table icons to help recognize the different components.

**Note:** If Administrator Console has not yet been used to turn on friendly names in the database the above display is what we see. If we are experimenting with a database in which friendly names have already been established, Database Console will automatically have the **Component View** toolbar button pushed in so that only friendly (that is *component*) names are displayed.

In that case, to see the above display we will have to make sure that the **Component View** toolbar button is pushed out so that we can see all items in the database and not just those to which friendly names have been given.

**Step 5: Link a Drawing from SQL Server**

We will link this drawing into our Manifold project to take a look at what was uploaded into SQL Server. To link the drawing into our project, click on the drawing entry to highlight it and then press the **Link** button in the Database Console’s toolbar.
Manifold knows this drawing was uploaded using Manifold spatial DBMS technology, including a spatial index, so we can choose if we want to import all objects in the drawing or only those within a particular area of interest. This latter option is very useful when working with very large drawings stored in databases. Quite often in enterprise applications we can have immensely large drawings, many gigabytes in size, which cover entire countries or regions as a single, seamless drawing stored within a large database cluster.

However, it is often the case that we might need to work with only a small portion of that large drawing, such as the area of interest involved in some local work, such as the region surrounding a particular city. The area of interest specification provided by this dialog makes such work possible, because otherwise the very large drawing stored on the database server would be far too unwieldy to conveniently use on a desktop machine.

For this example we choose the **Use all objects** option and press **OK**.

A new drawing appears in the project pane, using a database cylinder pictorial element as part of the icon to indicate that it is a linked drawing.

When we click open the drawing we see that it does contain the Carson City drawing, albeit without any formatting. We can only use formatting in such linked drawings if we have previously prepared the database table to store formatting through the use of Administrator Console.
The drawing appears in the correct projection exactly as it was when exported, since Manifold automatically stores full coordinate system information into the database when Manifold spatial DBMS storage is used.

So far in this example we have uploaded a drawing to SQL Server and now we have linked that drawing back into a project. If we are using Enterprise Edition we can have many people work with this linked drawing at the same time doing concurrent, multi-user editing of the drawing, albeit without formatting.

**Step 6: Using Administrator Console**

If we have Database Administrator Edition on hand we can configure the database table using **Administrator Console** so that subsequent use of the drawing by users employing lesser editions is much more convenient. In particular, we can provide a friendly name for the drawing stored and we can turn on formatting.

Assume for the moment that Database Administrator Edition is running on our machine. We launch Manifold and choose **Tools - Administrator Console**. If we have previously connected to the SQL Server database on this machine Manifold will remember the data source used in the **Data Source** box. If we have not previously connected to SQL Server, then we have to press the [...] browse button and use the **Data Source** dialog to connect to the desired data source.

We press the **Refresh** button and the Administrator Console will show the various tables that are in the database, identifying raster data with an image icon. However, because Administrator Console allows more advanced manipulation of tables it will not tag tables with a drawing icon, since we can decide whether a table should be treated as a drawing or not. Just like Database Console, the global filter settings in Administrator Console by default hide various internal tables.

We can determine which table is our uploaded drawing from the name of the table and also by noting the assignment of a projection and spatial index to that table. (The similarly-named table below our drawing's table is the spatial index for that drawing.)

Our first task is to assign a friendly, component name to use for our drawing.
We double-click into the Component cell and enter Carson City as a friendly name.

Our next task is to turn on server-side formatting storage for this drawing. This will allow Manifold to maintain formatting for the drawing within the database. We can do this using either of two methods: we can either open the Properties dialog for the drawing and turn on the Store formatting on server option, or we can turn on the Format column in the main display and click formatting on that way.

To set the properties, we click on the drawing to highlight it and then click the Properties button in the Administrator Console toolbar.

The Properties dialog shows how Manifold is managing this drawing within Manifold’s spatial DBMS infrastructure. As shown above, we check the Store formatting on server box to turn on server-side storage of formatting.
While we are at it, if this drawing will be edited as a linked drawing in a multi-user environment by more than one simultaneous user it pays to check the **Rely on server to increment version automatically** when we are working with a high performance DBMS like SQL Server. This offloads versioning incrementing onto the server for better performance when many users are simultaneously editing objects in the same drawing.

The other way of turning on formatting is to add a **Format** column to the Administrator Console display and to use that. This is just a different way of displaying and setting the same formatting option.

To add the **Format** column to the display, we click the **Columns** button in the Administrator Console toolbar.

In the **Columns** dialog we check the **Format** box and press **OK**.
This adds a **Format** column to the display. We can then double-click into the **Format** cell for our drawing and set the value to **Yes**. This turns on formatting for the drawing.

We can now closeAdministrator Console. Henceforth, any Manifold edition which connects to the database will now be able to use both friendly names and formatting in linked drawings.

**Step 7: Fast linking with Database Console**

The preceding step used Administrator Console to prepare the drawing. Now, whenever someone else connects to that database using Database Console they will have an enhanced experience with that drawing.

Let's assume we connect to the database again using Database Console.

![Database Console](image)

The first thing we see is that the **Component View** toolbar button has been automatically enabled so that the database listing shows only those items for which friendly names (that is, **component names**) have been assigned.

Database Console can tell that friendly, component names (like in a Manifold project) have been designated so it automatically comes up with component names turned on. It also knows to show the **Carson City** item as a drawing.

It is much easier to recognize our drawing when it is shown with the friendly name **Carson City** and when many other database objects do not clutter the display. In the above screenshot, we can see that the particular database we are using has had other Manifold components exported to it, a drawing and an image, and friendly names for those components have been established as well.
We can link the drawing by clicking on it to highlight it and then pressing the **Link** button.

That launches the **Import / Link Options** dialog which allows us to choose to use all objects in the drawing or only those in a given area of interest. The **Version** column is automatically set, as would be the server-side incrementing of version if that had been set using Administrator Console. Press **OK**.

The linked drawing immediately appears in the project pane using the friendly name assigned and a database cylinder in the drawing icon to indicate it is a linked drawing. It has been linked with correct projection information and correct location precision.
We can click open the drawing and see that it is exactly as we expect, albeit without any formatting. It has been enabled to use formatting but, so far, no formatting has yet been specified for the drawing.

**Step 8: Formatting**

Because the drawing has been prepared by Administrator Console to support formatting we can now add formatting. This is easy to do since we thoughtfully saved the desired formatting from the original drawing into a file.

With the drawing open we click into the foreground color well for lines, choose Theme... and in the Format dialog choose the CFCC field and the Load from File command. We load the formatting from the same file to which we saved formatting earlier in this topic.
This reloads the formatting previously saved into a file. Press **OK**.

The drawing now appears with thematic formatting. It has been enabled not only for concurrent, multi-user editing of features, but also for multi-user changes to formatting as well.

**Notes**

The above formatting process is something that is often done by the database administrator at the time the drawing is exported into SQL Server. The usual workflow is to have someone assigned to loading the database with required drawings and to have that person export the table, configure it with Administrator Edition and to assign initial formatting. Because most organizations are naturally protective of their centralized data warehouses and SQL Server installations those functions are normally accomplished by someone trusted to be a database administrator using Database Administrator Edition.
To the beginner the above example from start to finish may seem long because it enumerates every step, including routine steps that experienced users won’t even notice. It’s actually a simple process of uploading a drawing into SQL Server by exporting that drawing to a data source for SQL Server. The first time we create a data source for SQL Server that requires clicking through a few dialogs, but that is done only once. After that, Manifold remembers the data source for us and connecting to it is a simple point and click in the Data Source dialog. The drawing may then be imported or linked from the database using Database Console. Easy!

There are a few extra steps to configuring a drawing in the database for those who want to use friendly names and allow formatting within linked drawings stored in the database. That requires use of Administrator Console and a few extra steps. But the end result is so much simpler for ordinary users if we employ Administrator Console that virtually all organizations working with linked drawings in databases will have at least one copy of Database Administrator Edition available.

This example uses SQL Server Express, a free database product from Microsoft. It’s amazing that we can use free database products in this way, even those which do not have built-in spatial DBMS capability provided by their vendors. That expands usage of spatial DBMS with Manifold to just about every DBMS system one encounters.

One really interesting thing about using linked drawings as in the above example is that we can link drawings from different DBMS sources into the same project. For example, we could link drawings from Oracle, from SQL Server 2005, from SQL Server 2008, from PostgreSQL, from DB2 and even from various alternative DBMS products like MySQL into the same project and then proceed to open those drawings and copy and paste objects from one drawing into another, thus transferring data from within, say, Oracle storage into SQL Server or DB2 storage or vice versa.

Does storing drawings in databases make sense for smaller users, who might not have invested in even a single license of Database Administrator Edition to gain access to Administrator Console, and thus not have the ability to store drawings with formatting? Yes, because even without server-side formatting databases thus used provide vast capacity plus the ability to very efficiently work with only that part of the drawing that is desired. If drawings are not linked but imported, the entire drawing or a portion of the drawing can be imported into the project and then formatted in the usual way, perhaps using a previously saved format as in this example.

For those organizations that wish to perform multi-user editing of formatted drawing "in place," that is, the editing of linked drawings that remain in the database and are not imported into a Manifold project, the cost of a single license of Database Administrator Edition is still a bargain. Only a single license is required (to upload drawings and to enable formatting with Administrator Console), since all other users can import or link drawings from Manifold spatial DBMS using any Manifold edition, even Personal Edition, and from native spatial DBMS (such as Oracle, DB2, SQL Server 2008 or PostgreSQL) with Enterprise Edition.

A further reason to use spatial DBMS for storage is that only Enterprise Edition is required to upload images, which any Manifold edition can then import or link into a Manifold project. Linked images stored in databases are amazingly fast, as fast as using a linked image from an ECW. A very active GIS organization or professional user will therefore almost certainly will already have a database server in play if for no other reason than to store linked images in a high performance way.

**Technical Note on Primary Keys**

This example uses SQL Server, which has full support for the use of primary keys; however, even though it seems that all of the mainstream databases allow creating a primary key for a table, it is possible that one might encounter some database that does not. When exporting a drawing into a spatial database, Manifold attempts to create a primary key column in the destination database table using the OID field cited in the dialog at the end of the third step above.

Having a primary key column is important, because many ODBC drivers and OLE DB providers expose limited functionality for tables that do not contain a primary key. Depending on the software in use, a primary key can be one key column or a combination of columns, which taken together form a unique key.

If a table does not contain a primary key, some drivers will make that table read-only while some other drivers will consider that table read-write but with restrictions. A typical restriction when a primary key is lacking might be for the driver to make the table read-write so long as the database cursor (an internal programming concept) is forward only, which means that the client software can access row A and row B and row C in forward order but cannot access row A, then row B and then row A again.

Manifold contains a lot of internal code to deal with such goofy limitations and tries mightily to work around the limitations of various ODBC and OLE DB drivers. Manifold can even make some tables with restrictions like those above read-write in some cases. But no matter how Manifold may strive to work around such limitations arising from lack of primary keys it cannot do so in all cases.
A further reason for using primary keys is that many drivers contain optimizations aimed specifically at tables with primary keys. As a result, the driver and any client using that driver, such as Manifold, will perform much faster on tables containing primary keys.

The above limitations of drivers may also affect the ability of Manifold to interact with tables without a primary key in matters other than simple access. In some cases, linking a drawing from a table without a primary key might disable editing objects, but still allow adding or removing objects. In more extreme cases, the drawing might end up being read-only.

For these reasons, it is important to always use a DBMS that allows creation of primary keys and also not to later manually go into the database and mess with the primary keys Manifold creates. Manifold can work with a very wide range of DBMS packages that use a seemingly endless variety of ODBC and OLE DB drivers, so this is not a problem for anything remotely resembling normal use. However, programmers bent on doing custom, tricky things with the innards of databases should consider themselves forewarned.

**Tech Tip: Deletions in Database Console**

Deleting an unwanted drawing stored to SQL Server can be complex. See the discussion in the Database Console topic.

A Flashy Demo - Web Queries and KML

Every Manifold advocate should have at least one flashy demo that he or she uses to show off Manifold. While it is the deep power of Manifold doing things like topology overlays that impresses the GIS elite, to avoid putting to sleep those guests who may not have a deep appreciation of GIS it is important to keep the demo light and visually appealing.

Important: If you have installed 64-bit Manifold, do this example in 32-bit mode by launching Manifold System using the Manifold System (32-bit) shortcut. See the note on 64-bit Manifold at the end of this topic.

This examples shows a sequence of moves using Excel to grab dynamic data from the web, using it in Manifold and then grabbing part of that data and exporting to Google Earth. Fast and easy, it's a proven crowd pleaser.

Practice this routine. It's slow at first but after a few practice sessions can be accomplished with confidence in less than ten minutes. It goes so fast you'll spend more time explaining various wonderful things about Manifold than doing the demo.

This demo requires a web connection for the machine being used. In addition to Manifold we also need Microsoft Excel and Google Earth installed on the machine.

Step 1: Create a Web Query in Excel

Excel can be setup to automatically grab data from a web site using an Excel facility called web queries. Experts can create a web query in Excel by opening an Internet browser to the web site desired and then dragging and dropping the target data into an Excel session, using a special Paste As option. That's very flashy but easy to do wrong.

Another way to create a web query in Excel is the more traditional way using Excel menu commands shown in this topic. This is easier to remember, still flashy and virtually impossible to get wrong. For this example we will use the traditional way to create a web query that grabs data about recent earthquakes. Here's how:

Launch Excel
Choose Data - Import External Data - New Web Query

The resulting New Web Query dialog launches like an Internet Browser. It opens to your home page so you might want to set your home page to something respectable before doing this for an audience.

In the Address box, enter the URL to the USGS web page that gives a list of recent earthquakes in the US greater than magnitude one. The URL happens to be...

...but that's not possible to remember. Most people will launch an Internet browser just ahead of the demo and then use their favorite search engine to search for recent US earthquakes USGS or some similar search terms. That will find the USGS earthquake page, which has links to pages giving lists of recent earthquakes in the US and worldwide.

In fact, some people like to start this demonstration with a web browser already on the web site showing the list of recent earthquakes saying something like, "Wouldn't it be great if we could show the data in this page on a map in our GIS system and have it automatically updated, all without any programming?" A good performer always dangles a bit of bait in front of his or her audience to get their attention.

Once you have the page in your Internet browser you can copy and paste it into the Address box of the New Web Query dialog and press the Go button.
The earthquakes page can take tens of seconds to appear, because the USGS server is generating a table of recent quakes and sending it out to the page. This is your chance to distract the audience from the delay by talking about how this technique will work with any web page of locations, such as navigation buoy locations, locations of storms, locations of tracked animals or vehicles and so on.

When the page appears, the **New Web Query** dialog will place a yellow box with an arrow at the location of every table that is embedded in the page.

To find the data of interest, scroll down on the page (scroll bars in the dialog are not visible in the screenshots shown) to get to the table of recent earthquakes. The table is marked with a yellow box with an arrow. Note that the table has the magnitude, time and latitude and longitude locations of the quakes. Those who have been following along in previous examples know it is a **geocoded table**.

Press the yellow box with an arrow to select the table.
When the table is selected it will be highlighted and the box next to it will turn green.

Press the **Import** button on the **New Web Query** dialog.

That launches the **Import Data** dialog. Press the **Properties** button.
We are here in the **External Data Range Properties** dialog mainly for one very interesting box, the one we just checked that says **Refresh every ... minutes**. We’ve set the value to 30 minutes. What is immensely cool about this box is that we can tell Excel to go fetch data in background from the website so it always has current data in the spreadsheet. Our web query is like a robot in Excel that interrogates the USGS list of recent quakes every 30 minutes to get the most recent list.

In this case, we’ve told Excel to grab a table of recent earthquakes and to update the data from the web site every 30 minutes. That seems often enough for quakes. Press **OK** to exit the properties dialog and then **OK** to exit the **Import Data** dialog.

Back in Excel we see that the spreadsheet now contains data from the web site. If we were to sit around for 30 minutes we could see the numbers change as the spreadsheet automatically updates itself from the web query.
The table looks a bit messy, with missing values and a first column that looks like junk, but Manifold will digest this nonetheless.

Save the Excel spreadsheet to a file called **usquakes.xls** in some convenient folder.

**Step 2: Create a Linked Drawing in Manifold**

Launch Manifold and choose **File - Link - Drawing**. This immediately launches the **Data Source** dialog to allow choosing a data source from which the drawing should be linked.

We click the **Add Data Source** button to add a data source for our desired **.xls** file.

In the **Connect To** dialog choose **XLS Files** in the **Files of type** box and navigate over to the **usquakes.xls** file and open it.
This adds a new data source, but the default name used is not particularly helpful. We will give it a more memorable name.

In the **Name** box we enter a name that will help us remember what this data source is for. Press **OK**.
In the resulting Link Drawing dialog Manifold has already examined the .xls file and has pre-loaded the dialog with sensible choices. Manifold knows that LON likely means the longitude field and LAT the latitude field so these come pre-loaded with the right field choices. We’ll select all the fields except the first F1 column which is just empty junk at the beginning of the Excel table.

Pausing a moment to enjoy the priceless value of a demo where most dialogs work fine using default values, we press OK.

The result is that an ensemble of new components appear in the project. When giving this demo to an audience of very sophisticated GIS people who understand something about spatial SQL, we might take a few minutes to discuss how Manifold works with geocoded tables, using the information in topics like the Creating Drawings from Geocoded Tables topic. However, tread lightly on such matters when beginners are in the audience.

The new components created do have ugly names because of the naming conventions within spreadsheets, but this is an opportunity to do something with Manifold that even a novice will enjoy: we will rename a file.
Right click onto the linked drawing and choose Rename. Rename it to US Quakes so the audience can see it automatically renames dependent components and that doing things in Manifold is really easy, using clicks and context menus as one would expect in Windows.

When we click open the drawing the GIS people are impressed to see a drawing created on the fly from geocoded table in the XLS, but less technical people may be bored by the lack of pretty colors or lack of a map. Let's add pretty colors first and then later on (whet their appetites) we'll add a map.

**Step 3: Format the Drawing**
Click into the background color well for points in the formatting toolbar and choose Theme.... In the Format dialog use the MAG field with Natural Breaks and the Spectrum palette. We like to change the first color in the palette to a darker purple. Doing so shows how easy the dialog is to operate. Press OK.

After doing this demo once or twice most people cannot resist showing off different palettes while clicking the Preview box on and off so that people can see how interactive Manifold is. Cheap and flashy, perhaps, but fun and impressive as a matter of detail.
Examples

The result shows earthquake points colored by their magnitude, with more dangerous quakes colored more towards the red end of the spectrum. Someone in the audience will almost inevitably ask if points could be made larger for more powerful quakes.

Click into the size well for points and click **Theme...**. In the **Format** dialog choose a size range for points similar to that shown above. Sometimes it is fun to turn on the **Preview** box and ask for audience feedback as different sizes are tried. Getting the audience involved is Rule Number One for performers.
That's better. Now we see larger quakes with larger points. By now the audience is clamoring to see the points on a map. They've probably asked for this before but have been put off by the demonstrator. Making the audience ask for more is Rule Number Two for a performer.

**Step 4: Create a Map**

![Create Map dialog](image)

Import the **World_eg** sample drawing from the Manifold download site. The drawing is shown above, but the steps to import it are not shown in this example as the elementary importing of drawings is covered in many other places.

Right click on the **World_eg Drawing** in the project pane and choose **Create - Map**. In the **Create Map** dialog check both drawing boxes to participate in the map and press **OK**.
Open the map to oohs and aahs as people see where the quakes are on a real map. Pan and zoom a bit. Note that using the USGS site ends up creating at least one point at the 0,0 origin of latitude and longitude (by Africa) because the first row in the table after the column names does not have lat/lon values. You can promise the audience that later you’ll show them an expert Manifold trick that can be used to whip such deficient data into shape. For now, we ignore it.

**Step 5: Create a KML File**

Everyone likes to share the fruits of their work, so you can set up the next step by telling the audience you’ll show them a fast and easy way of communicating the data you have to others. We can do that by creating a PDF (a variation of this demo) from a print layout, or use the following technique of creating a Google Earth KML file that can be emailed to colleagues.

**Note:** Drawings ideally should be in *Latitude / Longitude* projection before export to KML or KMZ. Our drawing already is in *Latitude / Longitude* projection. See the note at the end of this topic for discussion of projections and KML.

Zoom into Southern California where there are always plenty of small earthquakes and select some of them (make sure you are on the quakes layer in the map).
With the quakes selected, choose **Edit - Copy** to copy those points.

Right click onto a blank spot in the project pane and choose **Paste**. A new drawing appears, helpfully named in a like fashion to its parent. GIS people in the audience with Windows skills know they are seeing something very interesting here, as this sort of thing is not done with legacy GIS systems.

Open the drawing and people will see that the formatting is retained. In the above illustration we've taken one step more (not shown) and have changed the thematic formatting for point size to increase the point sizes a value or two, say, from 2 to 4 and so on, so that the points appear larger. We have a reason for doing that, as will soon be clear. We've also renamed the drawing to **SoCalQuakes**.
With the SoCalQuakes drawing open, we choose File - Export - Drawing. In the Export Drawing dialog we choose KML / KMZ Files in the Save as type box and we provide the filename socalquakes.kml as the File name. Press Save.

The Export KML File dialog pops open to ask us which fields we would like to use for Name and Description. We'll use the MAG field giving magnitudes for the Name and the date and time field for the Description. Press OK.

What we've now created is a file called socalquakes.kml that is a "document" file for Google Earth. We can email it to someone and if they have Google Earth installed on their machine when they double-click the socalquakes.kml to open it, Google Earth will launch and display the contents of the file.

**Step 6: Display KML File in Google Earth**

Switch out of Manifold and into Windows Explorer and browse to the folder where the socalquakes.kml was stored. Double-click the socalquakes.kml file to display it in Google Earth. Google Earth will launch automatically and will zoom in from space to show our earthquake points in southern California.
The MAG field we used for Name will result in the points in Google Earth being labeled with the magnitude of the earthquake represented by each point. The points are still colored by the strength of the quake because that's how they were sent out by Manifold. The points are large and obvious against the clutter of the photographic background because we enlarged point size slightly before exporting the drawing.

If we look at the Google Earth information panes we can see that individual points have a description of sorts which is the date and time field. This is not the most powerful interface for handling data information, but then Google Earth is about visual interest, and lots of it, and not about manipulating or displaying data.

**Step 7: Adult Talk about Spatial Queries**

Google Earth is fun for all ages, but some folks with GIS expertise might be interested in just how you propose to use spatial magic to get rid of that spurious point near Africa. That's a chance to talk about how the drawing created from the XLS was actually created by an intermediate query from the linked table in the drawing.

```sql
OPTIONS CoordSys("Latitude / Longitude");
SELECT [Sheet1$].\$,
    AssignCoordSys(NewPoint(CAST([LON] AS LONGITUDE), CAST([LAT] AS DOUBLE))
FROM [Sheet1$];
```

You can open the query so that people with some familiarity with SQL can see how it works.

```sql
OPTIONS CoordSys("Latitude / Longitude");
SELECT [Sheet1$].\$,
    AssignCoordSys(NewPoint(CAST([LON] AS LONGITUDE), CAST([LAT] AS DOUBLE))
FROM [Sheet1$] WHERE [MAG] > 0;
```
The next step is to add just one line at the bottom, `WHERE [MAG] > 0`, which adds a qualifier to do all that spatial query stuff only for cases where the magnitude of a quake is greater than zero. Spurious lines in the table that don’t have data for latitude and longitude won’t have earthquake magnitudes greater than zero either, so this is a quick and dirty way of accomplishing the task.

After modifying the query in the above manner you’ll have to Run the query and then Relink the drawing back to the query. Practice this a few times before doing a live demo so you feel confident with the operation and show that confidence in your demo.

Operating the Relink dialog shows people how the drawing is linked to the query, and GIS people with computer science expertise are never failed to be impressed how the system can hang together so well that after the Relink the formatting is still intact.

The result is a map of earthquakes with no spurious points near Africa.

**Projections and KML Format**

Google KML and KMZ formats support Latitude / Longitude projection only. Drawings to be exported to KML or KMZ can be in any projection and will be re-projected on the fly into Latitude / Longitude during export; however, to avoid a potentially slow re-projection process it is wise to explicitly re-project drawings into Latitude / Longitude before export. This not only avoids a slow export, it also provides an opportunity to catch errors before export if the re-projection results in a strange display as might happen if the initial projection was not correctly assigned, say, after importing projected data from some format that does not store projection information.

Unlike drawings, images must be already in Latitude / Longitude projection to be exported to KML or KMZ.

**Notes**

Some demonstrators like this demo so much they go on to create a web site in Manifold IMS. this is especially interesting because as Excel refreshes itself with recent earthquake data Manifold IMS can also be told to refresh itself at a specified interval. This is a fast and easy way of creating a web site showing current earthquake data, with less than 15 minutes required for the entire process. If you add IMS to the demo, practice creating the web site on the target machine so that something dumb, like forgetting a Windows permission, won't trip you up in the live demo.

In addition to using export to Google Earth, many demonstrators will create a linked image in the Manifold map, taking imagery from TerraServer or other image server. That shows how Manifold can be used to bring together data from different web sources within the same project. For example, some people bring the World_eg
background into the map as an image linked from a Manifold Image Server. If you use that idea in a demo, work it out in advance so that you create a map from the linked drawing (which cannot be re-projected) and then show earthquake points on that.

Once pasted, the points copied from southern California will create a static drawing that has no link back to the original XLS. That's OK, as it illustrates how Manifold can grab data and move it from remote to local form.

This demo example was inspired by the magnificent presentations given by Manifold expert Dr. Arthur Lembo, who has used web queries together with Manifold at Cornell University to create rapid response web sites to help with disaster relief.

**Important Note when Using 64-bit Manifold Editions**

Due to a lack of required Microsoft facilities in 64-bit Windows systems, Manifold in 64-bit mode cannot export, import, export or link to DB, HTML, MDB, XLS or WKx format files. This includes no access to the MDB parts of Manifold MFD and MapInfo TAB imports. The workaround for importing or exporting such files is to launch Manifold in 32-bit mode by using the Manifold System (32-bit) shortcut, perform the export from or import into a .map project file and then re-launch Manifold in 64-bit mode using the Manifold System (64-bit) shortcut.

Linking is more complex: the data must be in some format usable in 64-bit mode within 64-bit Windows systems, such as a SQL Server database. Alternatively, the data can be kept within a Manifold .map project file and linked using the Manifold ODBC driver.

Although Microsoft is slowly moving forward towards 64-bit operation of Office and the JET components used by Access and Excel, at the present writing (2010) this is such a total kludge that while it is possible to get 64-bit access to Access or Excel it is just easier for most to continue using the 32-bit versions. See comments in the 32-bit and 64-bit Manifold Editions topic.

Creating Bordered Lines

When illustrating roads we will often want to show principal highways or other roads using lines that have "borders" on the edge of the lines with the borders naturally being spliced together at intersections.

This is an easy effect to achieve in Manifold. Although Manifold includes a bordered line style, using the default bordered line style does not achieve "splices" at places where several line segments come together. The technique described in this topic will create seamless splices at such intersections.

Step 1: Import and clean up the drawing

For this example we will import the `bay_roads_eg.mif` drawing.

After importing, we will create a map from the drawing, open the map and zoom in as seen above. Note that the example drawing contains points at the intersections of the road lines. We will eliminate them.

To do so, we set selection modes to select points and to not select areas or lines.
Choosing **Edit - Select By Type** will select all of the points in the drawing.

We can then choose **Edit - Delete** (or press the Delete button or press the Delete key) to delete the points.

**Step 2: Duplicate the layer**

Next, we will duplicate the layer. To do so, right click on the **Bay_roads_eg Drawing** layer tab and choose **Duplicate**.
A new drawing layer called **Bay_roads_eg Drawing 2** will appear in the map just above the original layer. The map will not change appearance since the duplicate exactly overlays the original layer and (thus far) is formatted identically.

**Step 3: Format the layers**

The final step is to format the two layers to provide the desired appearance. We begin by clicking on the lower layer tab (**Bay_roads_eg Drawing**) so that the focus is on that layer.

![Image of map with layers](image)

Change the thickness of the lines in that layer by clicking on the size button for lines in the Format toolbar and choosing 6 for the size.

![Image of map with thicker lines](image)

The result is that the lines in the lower layer become very much thicker.

We now click on the layer tab for the upper layer (**Bay_roads_eg Drawing 2**) so that the focus is on that layer.
Change the color of the lines in that layer by clicking on the foreground color well and changing the color to yellow.

With the color change we can see the yellow lines in the upper layer above the thick black lines in the lower layer.

We can now increase the thickness of the yellow lines in the upper layer by changing their size to 4.

This provides the desired effect.

Variations

We can create many variations by mixing different format styles in different layers.
For example, if we format the upper **Bay_roads_eg Drawing 2** layer as seen above we can create dotted line highways.

The dotted lines in the center of the highways are created because the upper layer uses black for the dots and a wider, size 4 yellow line for the outline of the dotted line.

We can create maps of great complexity using the above method. In fact, we can combine many layers into a map and arrange Zoom Ranges on the layers so that as we zoom in road lines that are initially shown as single, thin lines begin appearing as bordered lines as seen above. To do this, specify **Zoom Ranges** so that the layers showing thin lines switch off at the zoom level at which the bordered line layers switch on.

**Tech Tip: Interweaving Lines**
Maps of great depth can be created by stacking layers and using the formatting shown above. However, all objects in a given layer will be seen above all objects in layers below them. On occasion we may want to create an "interwoven" line that is sometimes above and sometimes below objects in different layers. This requires additional work, but it can be done if the visual effect merits the extra work. The rest of this topic describes an intermediate method that would rarely be done but is nonetheless interesting as an example of the great flexibility of Manifold tools.

Suppose we wish to draw an interwoven line that is sometimes above the yellow roads and sometimes below them. We create two drawing layers called above and below where the above layer is above the yellow roads layers and the below layer is below the yellow roads layers. Beginning at the lower left of the curved black line we draw a line in the above layer. We then click on the below layer to move the focus there. Turning on Snap to Lines, we can then draw another line that continues the curve, using Snap to be sure it starts exactly at the end of the previous line. We finish this next line before we need to go above the yellow roads.

We then click on the above layer and draw a line that continues the curve above the yellow roads. We continue in this way switching between the above and below layers as necessary to draw the line. The illustration above has had the above layer formatted in red and the below layer formatted in blue so we can see how the intertwining line is made up of many different lines in the above and below layers.
To achieve a bordered line effect for the interwoven line we duplicate both the above and below layers. The lower layer of each pair we format in black color with a size of 6. The upper layer of each pair we format in bright green with a thickness of 4.

An unpleasant effect occurs at the end of each green line where a black border appears. Because Manifold rounds the ends of lines with increased sizes, the black pixels at the end of the above layer are appearing above the green pixels of the Below 2 layer. Curing this is tedious, but possible.

The visually best way of fixing this is to create an additional drawing layer called ends and creating a line that crosses the boundary between the green lines.
If we zoom in we can see how these lines were created. With Snap to Lines turned on we can create a line that runs from the next to last coordinate of one line to its end to the next to last coordinate of the following line.

Zoomed out once more, we format the ends layer in green color with a size of 4. This achieves a seamless effect of an intertwining green line that sometimes goes above and sometimes below the yellow lines. Because the pixels line up perfectly there is no visual clue that the effect is made up of many layers.

The above exercise could be very tedious for a large map. Is there an automated way to sometimes move a line above and sometimes below another layer? If our data set consists of multiple lines where lines at intersections have some data attribute code such as a bridge or underpass code we can select "above" segments by this attribute, cut them out of the initial drawing and paste them into an "above" drawing layer.

If our drawing has no such data attributes, we can take a semi-automated approach of using a grid of lines at suitable resolution and the Intersect Lines transform to chop up a continuous line into many smaller lines. We can then visually select all portions that should be "above" the other lines using Add to Selection mode, cut them out of the layer and paste them into an "above" drawing layer. We can then use Join Lines to reassemble into a smaller set of lines the many lines created by the Intersect transform and left behind in the original layer.

In both of the above cases, creating "end" lines to bridge the dark pixels that appear between lines will be tedious, but at least we will not have to create the many parts of the intertwining line itself.
Georegister a Scanned Paper Map

A common use of Manifold is to create drawings that are based on paper maps. Although many maps are already available as drawings in digital GIS formats there are still many maps published on paper in the world's archives. To use information from paper maps we first use a scanner to create an image. We can then import the image, georegister it, and use it within Manifold.

This example uses a map originally published in a book that shows climatic zones in Australia. Our objective is to get this image into Manifold and to georegister it. The image is a small one printed as a small part of a page in an atlas. However, the data is interesting and we would like to make as much use of it as we can.

Before reading further in this example please read:

- Georegistration
- Georegistering an Image to Known Coordinates
- Error Surfaces
- Create a Table and Add Records

This is a long example even though the material it covers is quite elementary. It is lengthy because it includes many small details that a reasonably experienced Manifold user would take for granted.

In most cases of georegistration we will georegister an image to a drawing where both image and drawing contain discernable geographic features that can be used as control points. For example, the image might clearly show an intersection between highways that is also obvious in the drawing. Georegistration in such cases is fairly obvious and how to do georegistration in those cases should be readily apparent based on the topics cited above.

This example takes a much more complex case, which goes into a major diversion to create "control points" within a table. It shows how even if we don't have a drawing to which we can georegister we can still georegister if there are locations within the image that can be assigned latitude and longitude locations. In this example those locations are intersections of graticule lines in a printed map. In other cases, the locations within the image might be some clearing or other visible location for which we have latitude and longitude locations, perhaps because we have visited such locations with a handheld GPS and have recorded their coordinates.

For example, it's often the case in forestry applications where an image of a forest must be georegistered but there is no drawing to which it can be georegistered. In such cases foresters might visit actual locations seen in the image and note the latitude / longitude coordinates of such locations using a handheld GPS. Such locations might be clearings, intersections of logging roads or other features that can be distinctly identified in the image.

For this example we assume the Project pane and the Control Points pane are both open.

**Step 1: Scan the Image and Import into Manifold**

We lay the book on our scanner and scan in an image. Our scanner produces a .tif or other graphics format image that we can import into Manifold. We crop the image to Australia and convert it to RGB. We've named the image Oz, a friendly nickname for the enchanted land of Australia.
The paper map was printed in the book using a Winkels projection. When imported into Manifold the image is imported using the default Orthographic projection. We really don’t care what projection was used initially or how it was imported since the georegistration process will re-project the image as needed. Likewise, we really don’t care if the book was placed on the scanner with imperfect alignment. If the image was rotated the georegistration will remedy that as well.

**Step 2: Place Control Points in the Image**

Most paper maps have a graticule (lines of latitude and longitude) printed on the map. The graticule lines are usually placed at round numbered latitudes and longitudes.

If we examine the book we see that the graticule lines for our example have been placed every 10 degrees of latitude and every 15 degrees of longitude. By inspecting the map we can immediately read the latitude and longitude location of each graticule intersection. For example, in the illustration above the intersection immediately to the North of the printed "Wellington" caption is located at longitude 180 and latitude -40. [South latitudes and West longitudes are written as negative numbers.]

We will use graticule intersections in the image as control points. We intend to follow a procedure similar to that given in the Georegistering an Image to Known Coordinates topic.
Opening the Control Points pane we click on the **New Control Point** button and add control points at graticule intersections near Australia.

We name each control point with a short name that helps us keep track of which control point is which. When placing control points in a regular grid it is often helpful to use names like A1, A2, A3 and so on for the control points in the first row and then B1, B2, B3 and so on for the next row.

Note that when placing control points on graticule lines in this way all of the A points have the same latitude value, as do all of the B, C and D points. Likewise all the points on the same longitude line have the same longitude value. We will exploit this coincidence later in this topic to enter more rapidly the values of control points that will be used to guide georegistration.

We do not show the full illustration in this example, but the printed book shows that all of the A control points are at latitude -10, the B points are at latitude -20, the C points are at latitude -30 and the D points are at latitude -40. The 1, 2, 3 and 4 points are mostly at longitudes 105, 120, 135 and 150. The D4 control point is at longitude -165.

**Note:** When placing control points, it is often helpful in Tools - Options to uncheck **Autoscroll window on edit or selection process.** This prevents the image window from scrolling as we move the control point insertion cursor into the window. Also, it is often helpful to zoom into the image for each control point so we can place it more precisely.
After we finish placing control points the control pane will have a list of control points as seen above. [The coordinates for each don't really matter since they are abstract coordinates giving their position within the Orthographic coordinate system of the image.]

**Step 3: Create a Table with Control Points**

By reading the paper map we can determine the exact coordinates of each of the sixteen control points marked on the image. This will allow us to use a procedure like that in the Georegistering an Image to Known Coordinates topic. In that procedure we created a blank drawing and placed control points in the drawing and specified the latitude and longitude coordinate of each control point in the Control Points pane.

In this procedure we will take a slightly different approach. We will first create a table and then enter control point values into that table. We will then copy the table and paste it as a drawing of points. We will then load the control points pane using those points. This is a more indirect approach, but when large numbers of control points must be entered it is usually faster in the long run to exploit the editing and organizational powers of Manifold tables.

Follow the procedure set forth in Create a Table and Add Records to create a new table and to add sixteen records to it. Create each record with a value in the Name field only. Because this example places control points at the intersection of round-numbered latitude and longitude lines we will enter whole numbers only. It's often the case that we will want to enter latitudes and longitudes using either decimal degrees notation or degrees - minutes - seconds notation. Manifold tables can accept entry in either style as shown in the Create a Table and Add Records topic.
For each record we will specify only the Name, using names corresponding to the names we used for control points in the image. Since we don't specify the latitude or longitude value, each record will be created with a 0 value for latitude and longitude. The table appears as seen above after we have added sixteen records to it.

Now, a cool Manifold technique: select all of the A records. Double click into the Latitude cell of one of the selected records and enter -10. [For a refresher on selection techniques in tables, see the Selection in Tables topic.]
When we press Enter the value -10 will be placed into the Latitude cells of all the selected records. This is a fast way of entering the same value into more than one record. If we look back at the illustration showing control points in the image we can see that all of the A control points are on the latitude -10 graticule line.

We continue in this way to add latitude values of -20 for the B records, -30 for the C records and -40 for the D records.

We now will add Longitude values. Note that A1, B1 and C1 all have the same longitude. We select these records and double click into the Longitude cell for one of the selected records and enter 105.
When we press Enter the 105 value appears in the Longitude cell for all of the selected records. We next will select the A2, B2, C2 and D1 records and enter 120 for the Longitude of those records. [At this point we notice that it would have been smarter to number our D records as D2, D3, D4 and D5. Had we had the foresight to do so then all of the "1" names would have the same longitude, as would all of the "2" names and so forth.]

This trick of selecting several records at once to enter the same value in all of them is a very useful technique. If we don't want to use it we could always simply enter the latitude and longitude values for each record one at a time. However, taking some time to think through our task and planning to take advantage of patterns in our work allows us to work more rapidly and with less chance of error. It's a good example of how planning combined with skill in using Manifold results in more efficient workflow.

The result of our work is a table that contains records giving the names and locations of control points.

**Step 4: Create a Drawing from the Table**

To create a drawing from the table we Copy the table in the project pane and then Paste As a drawing.
In the Paste As dialog we choose only the Name as a field to be pasted as a data attribute into the drawing. The latitude and longitude of each point is implicit in the point’s position so it is not necessary to paste these. Because the point locations were entered into the table as latitude and longitude degree values, we check the Latitude / longitude coordinates box (the default setting).

See the Create a Map from a Geocoded Table topic for another example of creating drawings from tables using Copy and Paste As.

The Paste As operation creates a new drawing in the project. We rename it to My Control Points Drawing and open it. The drawing shows sixteen points that were created from the records in our table. It is in Latitude / Longitude projection. We will now use these points as control points.

To do so, we go to the Control Points pane and click the Load Points button. This dialog will create control points from all of the points in the drawing, using the specified field as the name of the control points. In the Load Control Points dialog we will use the Name field (of course) as the name for the control points. Press OK.
The result is that control points appear in the drawing at the location of each point. Each control point is named using the Name field of the point at which it appears.

**Step 5: Georegister the Image**

We can now georegister the Oz image using the control points specified in the My Control Points Drawing drawing. To do so we click on the image to make it the active window.

Press the Register button in the Control Points pane to launch the Register dialog.

We will use My Control Points Drawing as the reference. With sixteen control points in what is intrinsically a low accuracy project (we did, after all, scan a small image in a printed book) the Numeric method with order 3 will provide reasonable accuracy. We will also check the Save error surface as box to create an error surface so we can later see what the likely georegistration error is at different locations in the georegistered image. Press OK to georegister.
Manifold computes for a while and geregisters the image.

Because the reference drawing was in **Latitude / Longitude** projection the image now is also in this projection. We can see the image is in **Latitude / Longitude** projection because the latitude and longitude lines in the graticule are now straight horizontal and vertical lines. The internal scale of the image is slightly altered to preserve the original pixel aspect ratios as much as possible, so when seen by itself in an image window the image seems slightly compressed East to West.

We can open the error surface, called **Oz Error**, to see the root mean square error analysis. In the screen shot above we have used View - Display Options to specify a **Spectrum** palette to color the error surface so that different error values are more evident. Clearly, the central portion of the georegistration within the region covered by control points has low error in georegistration.

**Step 6: See the Georegistered Image in a Map**

Let's see how our georegistered image appears in a map together with a drawing that we know is exact. We import the **World** drawing published together with Manifold System for use as a base map. This drawing shows the countries of the world as areas. We then create a map using this drawing and open the map.
To show the Oz image in the map with the drawing we drag and drop the image into the map. It first appears as a layer above the drawing. We move the drawing layer above the image layer and then change the background color for areas in the drawing to transparent so that only the "edges" of the areas appear in the drawing. See the Transparent Areas topic for information on use of transparent colors as background or foreground colors with areas.

This allows the image to be seen through the areas in the drawing layer as seen above. We can therefore make a direct comparison between the shape of the georegistered image and the drawing that we know is very precise. Considering that we obtained the image by scanning a small image in a book the registration and accuracy are remarkably good. Very close inspection will show that the shorelines are slightly off in the extreme Southeast region of Australia and Tasmania, but the rest of the apparent shoreline is very well aligned to the drawing.

To see if the slight misalignment in the Southeast region is a result of the georegistration process we can drag and drop the Oz Error surface into the map as well. We change the opacity of the error surface to 50% so the lower layers can be seen through the error surface. See the Layer Opacity topic for information on changing the opacity of layers in maps.

We can see that a region of the lowest error values (in magenta color) passes right over the Bass Strait between Australia and Tasmania. It is most likely, therefore, that the lower correlation of the georegistered image and the known-accuracy drawing in the far Southeast is caused by lower accuracy in the original image. It was, after all, a small image printed in relatively low accuracy in a book to portray thematic information and was not intended for precision cartographic uses. The Winkels projection used in the book (a projection showing the entire Earth) also has its greatest distortion in the far Southeast.

**Step 7: Create Drawings by Tracing the Image**

We can use georegistered images for many purposes in maps just as they are. We can use them as backgrounds or as reference materials. For example, we can use the georegistered Oz image to see instantly in which climatic zones various cities might be located should we care to drag and drop a drawing of Australian cities into the map.

Another common use for georegistered images is the creation of new drawings by tracing. Images are intrinsically inefficient, so we can convert them into more efficient form by creating a new drawing and then drawing areas over the various regions shown by different colors of pixels in the image. See the Tracing topic for details.
To create a new drawing we begin by adding a new blank drawing to the map. Within the new drawing we can trace new areas. Let's create an area that covers the climatic region shown over central Australia. We turn off the error surface layer and then create a new area in the new drawing.

We create this layer using the Insert Area tool. After zooming into the map to a suitable degree we simply click along the edge of the dark yellow region seen in the image. The result is a new area (which we have formatted in yellow color with a speckled area style).

If we click off the image layer in the map we can see the world map layer together with the new drawing layer and the newly-created area. It's tedious, but if we wanted to we could use tracing to create new areas showing all the different climatic zones of Australia. We could add a field to the drawing used for tracing in which we could place a value for the different types of climatic zones. We could then use thematic formatting using the code for climatic zone to automatically color the new areas into different colors like those seen in the original image.

It's true that because the original Australia image is low accuracy we would have to interpolate by eye to draw the new climatic areas in the Southeastern part of Australia. However, the data set is obviously approximate and intended for a broad overview so such interpolation would be reasonable.

Notes

Many printed maps have graticules printed on them that can be used to repeat exactly the procedure above. The example map was a low quality, low accuracy, small map printed in a book. It was part of a map showing the entire world in Winkels projection, so the Australia portion of the map was quite distorted in projection. Nonetheless, the result of scanning and georegistration within Manifold was eminently useful. Had we started with a higher quality printed map, such as a USGS printed topographic "quad" map, our results would have been better.

Manifold and modern, high precision vector drawings used with Manifold are often much more accurate than printed maps. It is surprising to learn that a trusted atlas or even a chart intended for marine navigation may contain substantial inaccuracies. Such inaccuracies may arise from inaccurate data used to draw the map, distortions induced by the printing process or may even arise from poor quality projections. It is only recently that modern computers have made precision projection computations both automatic and routine.
When tracing areas such as the one created above there is a basic difference between the freehand, casual tracing possible in the region within Australia and the highly precise edge desired at the shoreline, where the newly-created area should precisely coincide with the detailed vector shoreline of the world map. The way to achieve a precise shoreline for the new area is to create the new area so that it substantially overshoots the shoreline. Next, since Australia is an area in the world map we can use the Australian area with the Clip with (Intersect) operator in the Transform toolbar to exactly trim the new area to the desired shoreline.

When working with scanned images of paper maps that show smaller regions of the world the graticule lines are usually aligned to "round" values using degrees, minutes and seconds notation. Part of the benefit of entering control points using a table is that we can enter values as read off the paper map using degrees, minutes and seconds notation and the table will automatically convert that for us to decimal degrees. See the Create a Table and Add Records topic for a detailed example showing how data entered in degrees, minutes and seconds can be automatically converted into decimal degrees.
Intersection Overlays

This is a small, but sophisticated, example that uses Transfer Rules, Split with, Clip with (Intersect) and Spatial Overlay commands. This example is an intermediate example that assumes basic familiarity with Manifold System.

Suppose we have a map with two drawings A and B that contain area objects that intersect each other. B contains green rectangles while A has blue triangles seen in 50% transparency so their overlaps with the B areas may easily be seen.

Both A and B have field names as seen in their tables above. The A drawing contains triangles and one field called Triangle with numeric values 1, 2, 3 or 4. The B drawing contains rectangles and one field called Square with text values Tom, Dick, Harry and Jane.

Our task is to create a new drawing that contains the spatial intersection of A and B, where all such objects have field values from both A and B. We also want the objects to be split up so that anywhere there is a boundary either from A or from B there will also be a boundary in the resultant drawing. This is a more complex task than simply finding the intersection of A with B where, say, just those parts of the B areas that are within the A areas are retained.

**Step 1: Get ready**

Like many GIS tasks, our task begins with a few preliminary steps to get organized. Begin by making a copy of B called B 2. Since we will operate on the B drawing we'll make a copy of the original drawing should we ever need it.
Right click onto the Triangle and the Square columns in the table windows and set the Transfer Rules for each to Copy in both directions.

We now need to arrange both drawings so that both A and B have fields of the same type. That is, we would like to equip the A drawing with a text field called Square and we would like the B drawing to have a numeric field called Triangle. With only two fields per drawing, we could quickly add one extra field to each drawing. However, if there are many fields involved we would like a faster way. Here is a fast trick:

Click on the A layer, click on one of the triangles and then Copy it. Click on the B layer and Paste the triangle into the B layer. This will add the fields from the A layer into the B layer. When pasted, the new triangle in the B layer will be selected. Since we don't need any triangles in the B layer, Delete it right away. The triangle will be gone but the new field structure will remain. Next, Copy a rectangle from the B layer and Paste it into the A layer. Delete the pasted triangle.
The result will be that both the A and the B drawings will now have the same fields. The newly-added fields will have default values (empty for strings, 0 for numbers) for the pre-existing objects. Note that the transfer rules established for these fields will be copied as well (which is one reason we set up the transfer rules as desired at the very beginning of this example).

**Step 2: Make boundary lines in A**

Since we will want to chop up the resultant areas by boundaries in both A and B, we’ll need some boundary lines in A with which to cut objects.

| [All Objects in A] | Boundaries | Apply |

Set up the transform toolbar as above and press **Apply**.

![Image of map with boundary lines drawn](image)

This creates lines in A that are the boundaries.

**Step 3: Cut areas in B**

We can now use the selected lines in A to cut the areas in B like wire through soft cheese.

| [All Objects in B] | Split with | [Selection in A] | Apply |

Make B the active layer by clicking on its layer tab. Load the transform toolbar as seen above and press Apply.

![Image of map with areas split](image)

This splits the areas in B along the boundary lines in A.
If we look at the table for B, we can see that new objects have been created. Because we previously set the 1:N Transfer Rules to Copy, each new area created from one of the four original rectangles inherited a copy of the Square value from its parent.

**Step 4: Create intersection of A and B areas**

We can now create the intersection of the A and B areas using the Clip with (Intersect) operator.

```
[All Objects in B]  Clip with (Intersect)  [All Objects in A]  Apply
```

Set up the transform toolbar as above and press Apply. This will use the areas in A (the lines are ignored) to clip the B areas down to only their region of intersection with the A areas.

As can be seen, the result is that all of the B areas that lie outside A areas are deleted. Because we previously split the B areas using the boundary lines in A, the edges of the A and the B areas are perfectly aligned.
There are fewer records in the table since some of the B objects that lay outside the A areas have been deleted.

**Step 5: Transfer A values to B areas**

The final step is to use Spatial Overlay to transfer the values of A areas to those B areas they contain.

We want to transfer all of the values of the Triangle field from the A drawing to the B drawing. However, we don't want to transfer the empty value of the Square field.

So, we right click on the Square field in the A drawing's table and uncheck the Transfer Column box. Press OK.
We then click on the B layer and choose the **Drawing - Spatial Overlay** command. Our **Source** is all objects in A and the **Target** is all objects in B with the method being to transfer values from areas to contained areas. This will transfer values from areas in A to all B areas that are contained by them. Press **OK**.

Like magic, the **Triangle** field in the B drawing will be populated with the appropriate value from whatever A area contains it.

If we turn off the A layer and then select some of the areas in B we can see that the result of our operation is indeed a group of areas that are the intersection of the areas in A and B that are correctly split along all boundaries that occurred either in A or in B.
From the table we can see that each area has correctly inherited the value of whatever original B field it had as well as the value of the A area that overlaid it.

**Notes**

Why did we take the time to create the same field structure in both drawings? The **Spatial Overlay** command can transfer data between layers in maps only when those layers have exactly the same field names and types, including the same transfer rules.

Why did we create boundary lines in A and then use the **Split with** command? Why not simply use **Clip with (Intersect)** directly? We could do that, if desired. The difference would be that the areas in B would not be split along the boundaries of the areas in A. For example, as executed above the procedure results in two areas in B in the locations marked by red arrows in the illustration below.

These were both part of the same rectangle initially. Had we omitted the **Split with** command these would still be part of the same rectangle and after the **Clip with (Intersect)** command would be one area.

Transfer Contour Line Height to Points

This brief example uses Spatial Overlay to transfer the **Height** value of a contour line to points that are on that line.

![Contour Drawing](image)

Our drawing contains a line. A series of points are superimposed on the line. Perhaps these points were created from the line using the Transform toolbar Points transform operator.

![Contours Table](image)

Examining the drawing's table we can see that the line has a **Height** value of 810 while the points all have a **Height** value of 0. We use the **Type (I)** intrinsic field in the table to show which records are points and which record is the line. Our task is to transfer the height value of the line to all of the points that are on the line.

**Step 1: Specify Transfer Rules**

In Manifold the Transfer Rules for each column specify how the column's values are transferred between objects. In the table, right click onto the **Height** column head and choose **Transfer Rules**.

![Column Transfer Rules](image)

In the **Column Transfer Rules** dialog, choose **Copy** as the method for **1 to N** transfers. Transferring values from a line to many points that lie on it is a one to many or "1 to N" transfer. Press **OK**.

**Step 2: Make saved selections**

The most convenient way of using **Spatial Overlay** is to save the objects involved into saved selections.
Select the line and save it as a saved selection called line in the Selections pane.

This is a very simple example with only one line. If we had many lines (as in a contour map) we would select all of them and save them as a saved selection.

Select the points.

This is most rapidly done in a large map by setting select objects to Select Points and then pressing CTRL-T or choosing Edit - Select By Type.

Save the selection as a saved selection named points in the Selections pane.

**Step 3: Apply Spatial Overlay command**

From the drawing, choose Drawing - Spatial Overlay.
In the **Spatial Overlay** dialog, choose line as the **Source** and points as the **Target**. All saved selections will be available in the **Source** and **Target** list boxes. Choose **Line to contained points** as the **Method**. Press **OK**.

Like magic, the **Height** value from the line is transferred to all points on the line (that is "contained" by the line). In this example we had only one line with a value of **810**, so all points receive that same value. If we had many lines each with different values then each point on a line would receive that line's **Height** value.
Color Areas by Counts

This example shows how to color areas by the number of points they contain.

Suppose we have a drawing that contains areas and points. The areas show states. Each point represents a customer. Such a drawing may have been created as a result of geocoding customer addresses.

We would like to color the states as seen above so that states with more customers have a different color than those with fewer customers.

This is a simple use of transfer rules and spatial overlay. Please begin by reading the Transfer Rules and the Spatial Overlay topics.

**Step 1: Prepare Saved Selections**

We first begin by selecting all points and then creating a saved selection called Points. We then select all the areas and create a saved selection called Areas. See the Selection topic for information on making selections and using the selections pane to create saved selections.

Now we are ready to set up some transfer rules and then do a spatial overlay.

**Step 2: Specify Transfer Rules**
If we open the drawing’s table we see that the six area objects have the names of each state. We first add a new field called **Total**. To do this we right click on the **Name** column head and then choose **Add - Column**.

In the **Add Column** dialog we add an integer column called **Total**. Using a 32 bit integer column allows us to count large numbers of items (over 64,000). If we wanted to use even larger numbers we could have used a floating point **Type**.

This adds a new **Total** column, with default values of zero for each object.

We shall now make ready the **transfer rule** desired. We begin by right clicking on the **Total** column and choosing **Transfer rules**.
In the Column Transfer Rules dialog we set the N to 1 rule to Count. The 1 to N rule doesn’t matter, since we will be combining many points into the single area that contains them so all we care about is the “many to one” N to 1 rule. Using Count tells Manifold to count up the number of items that occur in each area.

Since we don’t want to accidentally eliminate the names of each state via transfer rules, we also right click on the Name field, choose Transfer rules and then uncheck the Transfer column checkbox. This will prevent the Name field from being affected by any operation (such as a spatial overlay) that uses transfer rules.

Step 3: Perform a Spatial Overlay

We can now click back onto the drawing and then choose Drawing - Spatial Overlay. Spatial overlays are used to transfer information from some objects to other objects.
As the **Source** we will use the saved selection called **Points**. This is all the points in the drawing. As the **Target** we will use the saved selection called **Areas**. This is all the areas in the drawing. As the **Method** we will use **Points to containing areas**. Press **OK**.

Because the transfer rule for the **Total** column was previously set up to be **Count**, this spatial overlay will count all the points within each area and will place the resulting sum in the **Total** column for that area.

<table>
<thead>

<tr>
<td>58</td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

Like magic, we can see that each state area has acquired a nonzero value in the **Total** field, the value being the total number of points counted within that area.

**Step 4: Thematic Formatting**

We can now use the **Total** field to thematically format the drawing as desired.
Right click onto the Area Background Color well in the format toolbar and in the resulting Format dialog use values like those above. The Yellows palette has been lightened.

The result is a drawing where areas are colored in darker yellow if they contain more points.

**Dot Density Maps**

Areas may also be thematically formatted using Style to show regions with greater concentrations of a particular variable with a denser pattern. To do so, choose one of the area styles that show dots or dashes and then thematically format the Size of that style.
The thematic format above used the **Total** field to thematically format the **Size** from 10 (large size = sparse pattern) to 2 (small size = dense pattern).

The result, using white color for background so that the **Style** is the dominant visual feature, is to show regions with greater counts of customers with denser pattern.

**Formatting by Density**

In the above examples we've used a **Total** field that simply counts up the numbers of points in each area. Although that gives us a total number of points in an area, it does not give us the density of the points. For example, a very large area like Montana with 20 points would have the same **Total** value as a very small state like Delaware with 20 points and thus be colored the same, even though the customer density (customers per square mile or square kilometer) of Delaware would be much greater.

We can color areas by density using Active Columns to compute density and then using the Active Column to guide thematic formatting.

Before we create an Active Column we will turn on one of the intrinsic fields we would like to use, the **Area (I)** field.

<table>
<thead>
<tr>
<th>ID</th>
<th>Name</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>14</td>
<td>Wyoming</td>
<td>4</td>
</tr>
<tr>
<td>23</td>
<td>Nevada</td>
<td>6</td>
</tr>
<tr>
<td>24</td>
<td>Utah</td>
<td>5</td>
</tr>
<tr>
<td>28</td>
<td>Colorado</td>
<td>6</td>
</tr>
<tr>
<td>37</td>
<td>Arizona</td>
<td>9</td>
</tr>
<tr>
<td>39</td>
<td>New Mexico</td>
<td>19</td>
</tr>
<tr>
<td>52</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The table by default shows no intrinsic fields. To turn on an intrinsic field we choose **View - Columns**.
In the **Columns** dialog we check the **Area (I)** field and press **OK**.

That displays the **Area (I)** intrinsic field. To add an Active Column we right click on any of the column heads and choose **Add - Active Column**.

In the **Add - Active Column** dialog we choose a name for the new column, **Density**, and make it a floating point column. Press **OK**.

The default script for the Active Column is just a template that does nothing but which reminds us of what the structure of an Active Column script using VBScript should be.
We edit the script to the text above, which divides the total by the area.

For performance reasons, we left the default computation setting for the Active Column of on user request so the column is not automatically updated until we ask Manifold to recompute the Active Column.

We can do so by right clicking on the column and choosing Recompute.

The Density column will then automatically be recomputed.
We can now use the **Density** column in a thematic format to color the drawing by the unique values in the **Density** field.

That provides a nice illustration. However, we might want to color the drawing using **Natural Breaks** instead of unique values. To do so, we might want to adjust the Active Column script so that it results in larger numbers instead of the very small "E-11" density numbers currently used.

To do so, we rewrite the Active Column script slightly to multiply the densities by **1E+12** (one times ten to the twelfth) to make the density numbers bigger.
After using **Recompute** one more time we can see the numbers are in a more intuitively understandable scale.

We can now thematically format using the **Natural Breaks** method and the **Density** field.

The result is a very clear drawing that shows how the states involved fall into three levels of densities.

Combine a Surface and a Drawing in a Map

This example shows use of a surface layer in a map together with a drawing layer. We color the surface by height.

**Step 1: Locate and download the example files.**

The surface used is the **Montara Mountain** (California) 1:24K-scale DEM (Digital Elevation Module) downloaded from the USGS web site. This DEM is located just south of San Francisco and is provided by USGS in SDTS format.

The drawing used is the corresponding "DLG" (Digital Line Graph) USGS vector map, also in 1:24K-scale and also distributed by USGS in SDTS format. This file is also known as **Montara Mountain**, after the name of the paper "quad" map both the DEM and DLG cover. The STDS DLG quad contains several different data sets, including those for transportation, hydrology, boundaries and so forth. We have downloaded the files for transportation.

To locate the files, visit the USGS US Geodata web page, currently at [http://edc.usgs.gov/doc/edchome/ndcdb/ndcdb.html](http://edc.usgs.gov/doc/edchome/ndcdb/ndcdb.html) and drill down into the 1:24K DEM and DLG pages to find and download these maps. See the Where to Get Maps topic for notes on USGS sites. **Note:** USGS has recently embarked in a series of deals to give public data to private firms for their benefit. USGS DEMS are still available for free download, but you may have to download them from private firms who will also offer downloads for a fee in addition to the free USGS SDTS DEM downloads.

The maps will download as compressed files using **.tar.gz** archiving/compression. See the Import a Shapefile topic for notes on decompressing such files using WinZip (don’t forget to uncheck the “TAR file smart CR/LF conversion” box in WinZip’s Options). The result of decompressing an SDTS **.tar.gz** archive will be a folder full of various SDTS files. It is therefore wise to place each **.tar.gz** file in its own folder first and then decompress it.

In this example, within the **tmp** folder on our computer we have created two directories, a **montara_mountain_CA SDTS DEM** folder and a **montara_mountain_CA SDTS DLG** folder. Within the DLG folder we have further created a **transportation** folder. We then uncompressed the two **.tar.gz** files into these folders. SDTS data sets consist of so many files that we will be glad we took the time to keep them well organized through sensible use of folders in our Windows file system.

**Step 2: Import into Manifold**

Launch Manifold. We will begin by importing the surface. Choose **File - Import - Surface** and choose SDTS Files in the **Files of type** box. **Note:** SDTS files can contain surfaces and drawings so Manifold's SDTS importer appears both under **File - Import - Surface** and **File - Import - Drawing**. Regardless which menu path is chosen the SDTS importer will correctly detect the presence of surfaces or drawings in the file and import the data correctly as either a surface or a drawing.

Browse over to the folder in which the downloaded SDTS **.tar.gz** file was extracted. Although Windows Explorer would show us many SDTS files, only one of them is a **.ddf** file that summarizes the content of the data set. Only this **.ddf** file is shown in the import dialog. We choose the **.ddf** file in the folder and press **OK**.
In the **Import SDTS Data Set** dialog we leave the default choices as they are and press **OK**.

The result is that new surface, terrain and comments components appear in our project. We will next import the drawing.

![Import SDTS Data Set dialog](image)

Once again we choose **File - Import - Drawing using SDTS Files**. We browse over to the folder where we extracted the SDTS DLG drawing files. For this example, we will use the roads files from the transportation layer. We choose the `.ddf` file in the transportation folder and press **OK**.
We will use the default settings once more and press \textbf{OK}. Later in this example we will see that using the default settings is a minor mistake. For now, we will make the mistake and then later correct it.

The result in the project pane is the appearance of more components, including a drawing component. Note how imports from SDTS are self-documenting.

\textbf{Step 3: Create a map}

We choose \textbf{File - Create - Map} or use the \textbf{Create} button in the project pane to create a map.
In the **Create Map** dialog we check the surface as the component to be used to create the map. We could have used both, but when using new data sets we like to create maps using one component and then drag and drop the other components into the map. That assures the map will be created using the projection of the one component used to create it. This is important when working with potentially large surfaces since map display will go fastest if the map uses the same projection as any large component it contains.

If we double click open the map thus created we see it contains one layer, the surface used to create the map. The surface is seen using default display options.

**Step 4: Color the surface by height**
To provide additional visual cues for reckoning elevation as well as to provide a more striking image we will color the surface by the height of each pixel.

To do this, choose View - Display Options to launch the Display Options dialog. In the dialog choose the Spectrum preset for the Palette and press Apply. Leave all other options as indicated in their default settings. The settings ask Manifold to show the scene with shading as if the Sun were in the East at a 45-degree angle above the horizon. This is not exactly a realistic setting since the Sun is only directly in the East at Sunrise when it is well under 45 degrees above the horizon. However, the settings provide a pleasing visual effect. Press OK.
Well... that's certainly a striking image! Manifold has colored the surface using the palette intervals and colors indicated.

**Step 5: Drag and drop drawing into the map**

We will now add the drawing to the map.

Drag and drop the drawing from the project pane into the opened map window. It will appear as a layer just above the surface.
Well... that's certainly an ugly effect! What happened? The drawing as currently structured contains numerous areas that completely cover everything below so the surface cannot show through. In addition, the drawing contains numerous points that are shown by default as small circles. To see just the roads we ideally would want only lines in this drawing.

We also have points and areas because of the small mistake we made when importing the drawing.
If we recall the SDTS import dialog we used to import this drawing, we simply used default settings for import. Default settings check all the Modules boxes, which happen to include modules for points, lines and areas. If we only wanted lines we should have unchecked the points and areas boxes (scrolled out of sight in the illustration above) and imported only the lines modules.

**Step 6: Remove areas and points from the drawing**

To remedy the problem we will select all points and areas in the drawing and delete them.

To do so we push in **Select Areas** and **Select Points** in the Select Objects buttons of the selection toolbar and we push out **Select Lines**.

We then choose **Edit - Select By Type** to select all objects in the active drawing that are chose by the Select Objects filter buttons.
All areas and points in the drawing are selected. To delete them we press the **Delete** key on the keyboard or choose **Edit - Delete** in the main menu.
When the areas and points are deleted only the lines appear in the drawing layer. This allows the surface to be seen.

**Step 7: Alter surface transparency**

The preceding image is certainly spectacular. However, the intensity of the colors in the surface make it difficult to see the road lines. If we wish to provide greater emphasis to the road lines we can de-emphasize the surface by making it partially transparent. To do so, we open the Layers pane using `SHIFT-ALT-L` or `View - Panes - Layers` from the main menu.

Press the **Opacity** button in the layers pane to show opacity for each layer. Double click into the 100% opacity value for the surface layer and change it to 50%.

This immediately de-emphasizes the surface by allowing the white background to shine through it. The result is a display that shows roads to a much greater degree than before.

We can also combine different levels of surface opacity with various formatting options for the drawing layer.
Here we have zoomed into the western edge of the map. The opacity of the surface has been set to 75%. The lines in the drawing layer have been set to size 2 to make them thicker. Amazing detail, isn't it? One can see how the good citizens of this part of California like to place their homes on hillsides. Note how a road in the center of the image crosses what appears to be a stream channel. If we like, we can import the hydrography layer from this SDTS file and see if it shows a stream in that location.
Here we see a view zoomed into the eastern edge of the map, where the road crosses over the valley of the San Andreas Fault. The flat area is the San Andreas reservoir that provides water storage for the city of San Francisco. The reservoir running from upper left to lower right and the valley down to the lower right mark the location of the fault itself. The San Andreas Fault was the locus of the earthquake that destroyed San Francisco in the early part of the 20th century.

**Step 8: Add a second drawing to provide context**

Readers familiar with the Bay area might wonder where exactly is the Montara Mountain quad we see. To provide context, we can add another drawing to the map.

We will import the `bay_land_eg.mif` drawing used in the My First Map example and drag and drop it into the map. It appears above the other layers so we will right click on its layer tab and use Order to send it to the bottom of the layer stack.

We can now see the surface and roads drawing in position above the `bay_land_eg` drawing.
If we zoom into the lower left corner of the surface we can see it is located at Half Moon Bay. For this illustration and the one above lines in the roads layer have been set to a size of 1. Opacity of the surface is still at 75% so the gray areas of the bay_land_eg drawing can partially show through.

For Advanced Users

In this example we’ve combined drawings and a surface in an elementary way within a map. Note that part of the surface extends beyond land areas because USGS provides DEMs as rectangular data sets. Suppose we wanted to remove that part of the surface that did not extend over land?

One way to do this is to copy the surface and paste it as an image and to select those pixels that are over water and delete them (turning them into invisible pixels). The trick is to select only those pixels. To do so we can use a drawing as a guide. We do this by converting the drawing into an image using the Tools - Make Image command. We then force the resulting image into only black and white and (after matching it to the target image derived from the surface with Match ) use it as a selection mask to select only those pixels over water. We can then delete them.

See the Overlays topic for use of these same imported drawings to overlay the 3D terrain with lines from the roads drawing.
Adding a Legend

This topic shows how to add a legend to a surface. It shows simple methods for customizing the appearance of legends. The procedures shown here apply to creating and customizing legends for other components, such as maps and drawings.

**Step 1: Import a surface and color the surface**

Use the procedure set forth in Combine a Surface and a Drawing in a Map to import the **Montara Mountain 1:24K-scale USGS SDTS digital elevation module**. Open the surface and use the View - Display Options dialog to color it with the **spectrum** palette.

![Display Options dialog](image)

Click into each of the intervals in turn to edit the values for each color to an even number, such as 0, 300, 600, 900, 1200, 1500 and 1800.
The result is a surface that has been colored by the thematic format (palette) given in the display options dialog.

**Step 2: Show the legend**

Launch the **Legend** dialog with **View - Legend**.

Check the **Show Legend** box and choose **None** in the **Align** box. This will turn on the default legend. Because there is no specified alignment we will be able to drag the legend to any position in the surface window. If we press **OK** at this point the legend will appear in the surface window. However, before pressing **OK** we first will make some minor adjustments.
The name of the surface (and thus, the first line in the legend) is still the same long name automatically given to the component on import. We will improve this. Check the Customize legend box and then click on the first line in the legend pane to select this element for editing.

Change the string in the Text box from [Component] to Elevation. Note that the first line in the legend preview pane also changes. This changes the caption from an automatically generated escape sequence that prints the name of the component to the specific text string Elevation.
Push OK and the legend appears in the surface window. We can drag it to any position in the window desired.

**Step 3: Modify the legend color samples**

The legend created by default is fine for many purposes. If desired, we can change the style of the legend by changing settings in the **Legend** dialog.

We begin by clicking on the main element to highlight it, a dynamic element that gives formatting for the surface.

With the element highlighted we press the **Flatten** button to convert the dynamic element into a series of individual elements.
We can now individually manipulate the legend elements. We begin by highlighting the **Height** text element and then deleting it.

We will now change the shape of the samples used in the legend entries. We begin by clicking on the **1800** element to highlight it. In the **Type** box choose **Color: Square**.
This changes the style of color sample used from a wide rectangular box (the default) to a smaller square box.

We can click on each element in turn and set the **Type** for each to **Color: Square** to change all of the samples to this type.
Press **OK** and the legend appears using the new types.

**Step 4: Show two columns in the legend**

So far the legend shows all entries in a single vertical column. We can use more than one column in a legend for a more horizontal legend style.

Open the legend once more with **View - Legend**. Click on the **900** element in the legend preview pane and click the **Add Element** toolbar button.
This adds a new element just above the previously highlighted element. By default, the new element is a Text line.

To change the new element, we change the value in the Type box from Text to Vertical Separator.
The text element shown in the legend preview pane changes to a **vertical separator** element.

If we now press **OK** we see that the legend is drawn using two columns with the column break happening where the vertical separator element was inserted.

If we like, we can use a vertical separator line to set off columns. To do so, we open the legend again with **View - Legend**.
Click on the **column** element in the legend preview pane and choose **Vertical Separator with Line** as the **Type**. The element changes to **vertical separator with line**.

Press **OK**. The result is a legend in two columns where a vertical line separates the two columns.

**Step 5: Changing margins in a legend**

We might want to vary the amount of margin space between the contents of the legend and the legend border. This value is set by the **Margin** box. The default value is 8 points.

To change the margin, launch **View - Legend** and change the **Margin** value to 15 points. Press **OK**.
The legend reappears with greater margin space between the contents and the outside border. Additional space also separates the columns from the vertical separator line.

**Step 6: Create a horizontal legend style**

We can create a legend where every element is in a separate column for a purely horizontal style.

Open the legend with **View - Legend**. Set the **Margin** back to the default value of 8 points.

![Legend settings](image)

Click on the entries in the legend preview pane and use the **Move Up** and **Move Down** keys to rearrange them so the topmost is 0 and the lowest is 1800.

Next, add a **Vertical Separator** between each element. This places each element in its own column.
To tighten the legend arrangement, change the Align text setting to **Left**. This will bring the labels closer to the color sample boxes. Press **OK**.

The result is a pleasant legend that is horizontally oriented. Such legends take a few extra mouse clicks to create but are well suited for use within print layouts that use paper in landscape orientation.

**Step 7: Add a legend to a print layout**

We will frequently want to add legends to print layouts. The following layouts use small windows to better fit into this documentation. In real life we would use larger windows for more convenient operation.

Before creating the print layout we hide the legend currently displayed for the surface by choosing **View - Legend** and in the **Legend** dialogue un-checking the **Show Legend** box. If we create a print layout from a component where the component is already showing a legend the display in the print layout will automatically show that legend as well within the component.

For the sake of this example, we prefer to create an independent print layout element showing a legend so that we can move it about in the layout independently of any layout element that shows the surface.
Create a print layout using the Montara Mountain surface. We open the layout, and **CTRL-ALT-click** onto the surface to select it for editing. We drag the lower edit handle up to resize the element so that it does not fill the entire page.
This leaves some white space in the bottom of the page where we can place a legend.

Choose the Insert Legend tool.
Draw a box with the tool where the legend is to appear, dragging open enough space for a legend to fit.
The legend appears in the print layout. Manifold knows which legend is associated with the only component that appears in the layout. If multiple components appeared in the layout, then when we used the **Insert Legend** tool the system would have raised a secondary dialog allowing us to pick the parent component for the legend.
If desired, we can **CTRL-ALT** click on the legend and move it to any position in the layout independently of the surface component in the layout. Click anywhere outside the legend to deselect it.
If we zoom in we can see that the legend is the same as created in the previous steps of this example.

**Changing the Legend in the Layout**

Note that legends are configured based upon their parent component. If we would like to change the appearance of this legend, we can do so using either of two methods:

- We can right click on the legend in the layout, choose **Edit** and then configure the legend as desired. Double clicking the legend will also open it for editing.
- We can open the surface in its own window and then use **View - Legend** to configure the legend as desired.

Any changes made in the layout to the legend will appear in the legend in the surface window and any updates made in the surface window will appear in the layout window legend as well.

Graticule Labels in a Print Layout

In print layouts we frequently would like to add latitude and longitude labels to the edges of a map or other component in the layout.

Creating graticule labels is a two-step process in Manifold: first a graticule is configured for the element within its own window and then the graticule is used to guide the creation of labels in the layout window.

In this example we create a layout using one element, a drawing of Mexico, with graticule labels on its border.

Step 1: Configure a graticule in the drawing

We begin by importing a drawing of Mexican provinces, using either the Mex boundaries.mfd or mexico_eg.mif sample files on the Manifold CD.
Examples

To show a graticule we open the drawing and choose View - Graticule command.

In the Graticule dialog we check the Show graticule box and then use the Suggest button to get a suggested range of latitudes and longitudes to use. We then round these off by eye to go from longitude -120 to longitude -85 and from latitude 10 to latitude 35. We use a spacing of 5 degrees for both latitude and longitude. Press OK.

The result is a graticule that neatly covers Mexico with a reasonable grid of latitude and longitude lines. How did we get the numbers we entered into the Graticule dialog? Through experience we know that a 5 degree grid is about right, with graticule lines neither too far apart nor too close together. Too get the other values we started with the Suggest button and then rounded them to the nearest 5 degree value. By trying a few different values (it only takes a few seconds to see how the graticule looks in the drawing) we quickly zeroed in on what values worked well to cover the Mexico drawing.

**Step 2: Create a layout and turn on graticule labels**

Next we create a print layout by right clicking into the project pane and choosing Create - Layout. We create the layout using the Mexico Drawing component.
Since we left the graticule turned on in the drawing, the drawing appears in the layout with a graticule overlaid. To add graticule labels we right click onto the drawing in the layout and choose Properties.

In the Properties dialog we choose coordinates (graticule) in the Border option. We also check the Deg-min-sec format box to use a degrees, minutes and seconds format for the latitudes and longitude labels. Press OK.
Examples

Labels now appear on the border of the drawing.

If we zoom into the layout we can see that the drawing now has a rectangular borderline drawn about it. Where the edges of the border are intersected by the graticule lines a tick mark appears with a label giving the longitude or latitude for that graticule line. Note that the labels are written using degrees, minutes and seconds notation, which appends a N, S, E or W to indicate North and South latitudes or East and West longitudes. Because the graticule is aligned on round numbers every five degrees there is no need for minutes or seconds in the labels, so we've used the default Rounding of 0.

Variations

Suppose we would like graticule labels on the edges of the drawing but we don't want to show the graticule itself? That's easy to do. Right click on the drawing element in the layout and choose Properties.
In the Graticule option change the default auto setting to hide. The auto setting will show the graticule if it is shown in the drawing and will hide it if it is hidden in the drawing. The hide setting will always hide the graticule. Press OK.

The result is that the graticule no longer appears in the layout, but the graticule labels still appear. This is often a useful effect in maps of small regions where latitude and longitude lines form a very rectangular grid. However, it can be confusing in maps where graticule lines are highly curved because it is not clear to the person using the map how to extrapolate from the labels on the edges into the interior of the map.

To get an example of how graticule labels look in the default decimal degrees format we can right click on the drawing element in the layout, choose Properties and uncheck the deg-min-sec format box.

In a zoomed-in view we can see that the labels along the upper edge have dropped the appended W and now are negative numbers to indicate West longitude.

View - Graticule
Align Items in Layouts

This example presents a quick sequence of alignment commands that are used to align text in a print layout using tools on the Alignment toolbar. The print layout contains a map of Europe and four text boxes that are arranged in the four corners of the layout. The task is to move the texts so they neatly line up with each other.

Before we begin aligning elements, let's change the selection style so that selected items are shown with a red border only and not with the default, filled-in red dot pattern used for selections.

Click open the Selection Style menu.

Choose Border.

Step 1: Select and align leftmost text

We'll begin by aligning the lower left text so that it is even with the upper left text.
Click on the lower left text to select it.

CTRL-ALT click on the upper left text to select it for editing. Selecting another item for editing using CTRL-ALT click will not deselect the lower left text. When an item is selected for editing, it becomes the primary selected item.

Press the Align Left button on the Alignment toolbar to move the lower text box to the left to align to the primary selected text box. The text will move to the left.
Step 2: Select and align upper text.

Next we will move the upper right text up to align with the "Europe" text in the upper left. We begin by **SHIFT** clicking on the upper right text. This will select it without deselecting any other items.

We then **CTRL** click on the lower left text to deselect it. A **CTRL** click toggles back and forth between selected and unselected without affecting other items.
We now have only two items selected, with the upper left text being the primary selected item.

Press the **Align Top** alignment button to move the upper right text upward so it is even with the primary selected item, the "Europe" text in the upper left.

**Step 3: Select and align rightmost text.**

We will now align the two rightmost texts using a similar procedure.
CTRL-ALT click on the lower right text to make it the primary selected object.

CTRL-click on the upper right text to deselect it. Both texts on the right are now selected with the lower right text being selected as the primary selected object. We will move the upper text to the right to align with the lower text.
Push the Align Right button to move the upper text box to the right to align with the primary selected text in the lower right.

**Step 4: Select and align lower text.**

The final step in this example sequence will be to align the lower texts. We will move the rightmost text down in alignment with the lower left text.
We **CTRL-ALT** click the lower left text to select it as the primary selected object and then we **CTRL** click on the upper right text to deselect it. We now have the lower left text as the primary selected item and only one other item selected, the text box that is to be moved down.

Press **Align Bottom** to move the text on the right down so that it is aligned to the lower edge of the text box at lower left.

The result is a symmetric layout with evenly aligned text.
Text Box Formatting and Alignment

The procedure above neglected to mention an important point in order to show a simple example of how to use
the alignment tools. Because text boxes can be drawn much larger than the text they contain it is important to
align the text within the text box using the Format Toolbar controls in a way that anticipates how the alignment
commands will be used.

The alignment tools in the Alignment toolbar will align the edges of the text boxes. If we want two texts to be left-
aligned to a common vertical margin, we should not only align the text boxes but we should also use the Format
toolbar to left align the text within those boxes. This can be done either before or after the above procedure.

For example, if we look at the label in the lower left corner, the default format setting is that the text is centered
within the text box. This leaves some space between the left edge of the text box and the beginning of the actual
text. If we used the Align Left command with this text box to align it to the left edge of another text box, the text
boxes will be aligned but the text within this text box will appear slightly indented due to the space between the
left edge of the box and the beginning of the actual text.

We can remedy that by CTRL-ALT clicking on the text box to select it for editing and then using the Format
toolbar to left align the text within the box.

In the Format Toolbar we can click Align Left to left align the text within the text box.

We can also click Align Bottom to align the text to the bottom of the text box, a good idea when aligning single
lines of text so that they all share the same base line for the characters.

The left alignment is visible, but the bottom alignment is not because the text box is very small compared to the
size of the text within it.
Likewise, the texts that are to be aligned on the right side of the layout should be right aligned within their text boxes. We can do this by \texttt{CTRL-ALT} clicking each one to select it for editing.

Each will have the default formatting of being centered within the text box.

We can click \texttt{Align Bottom} to bottom align them and then click \texttt{Align Right} to right align them within the text box.

If the labels on the right are aligned to the right within their text boxes, when the text boxes are aligned to a common margin on the right side the texts will also be aligned to that margin.

\end{itemize}
Create a Print Layout from a Table

In this example we create a print layout from a table using the sample *Mexico_eg.mif* drawing from the Manifold CD. To simply print a table we could always just open the table and choose File - Print; however, using a layout can give us better control over the appearance and format of the printed table.

**Step 1: Import drawing and configure table**

Import the *Mexico_eg.mif* drawing that is found on the Manifold CD.

![Mexico_eg Drawing](image1)

Open the table.

![Mexico_eg Table](image2)

Note that the table includes the **ID** field that gives the object ID. If we wish to print the table to get a record of the attributes we may decide to not print the **ID** column. To get rid of the **ID** column we right click onto the **ID** column header and choose **Hide**.

![Mexico_eg Table](image3)

That's better!

**Step 2: Create a print layout from the table**

A fast way to create a layout from the table is to right click onto the table in the project pane and choose **Create - Layout**.

![Create Layout](image4)

Doing so automatically opens the **Create Layout** dialog with the table that was right clicked already highlighted to use as the component from which the layout will be created.
Press OK to create the layout using the **Mexico_eg Table** component. This creates the layout using the table as the main element in the layout.

A new layout will appear in the project pane. It is shown indented under the table that is the main element in the layout. Double click the layout to open it.

The layout opens using the default page setup for the default printer, with as many pages used as are needed to display the contents of the table. The table is centered vertically. Since tables are often printed using multipage layouts, it is a good idea to review the Multipage Layouts topic to understand how selection and editing is done when more than one page is used for a layout.

**Step 3: Adjust the table**

To change any settings we must select the table for editing by **CTRL-ALT** clicking it.
When the table is selected for editing it will be shown in selection style (we've changed the selection style to **Border** so that the table is more clearly visible) and edit handles will appear.

The red outline shows the extent of the layout element with which the table appears. To reduce the white space at the top and bottom of the table we can resize the layout element by dragging the bottom middle edit handle upwards.

Making the table element less tall will reduce the white space at the top and bottom of the table. Note that the table text will occupy the same amount of space regardless of how we resize the table element box because the size of the table is fixed by the physical size of the font used for the table text. The font size may be changed using the Format toolbar, which is enabled when the table is selected for editing.

**Step 4: Adjust page orientation and number of pages used**

From the illustration above it is clear that using a **Landscape** orientation for the page might possibly allow the entire table to be printed on a single page.
If we use File - Page Setup to change the paper orientation to **Landscape** we can see that this does, in fact allow the entire table to fit on a single page. We can now adjust the layout to use only one page by using the **Layout - Pages** dialog.

Change the **Pages** numbers to 1 in both boxes for a single page.

The result is a table printed on a single page in **Landscape** orientation.
Why go through so many steps just to print a table? Using a layout allows us to add other text elements to the layout, for example, a title block with copyright or other information or perhaps other text boxes that automatically print page numbers, time and date, the names of files or components used or other information.

We can also adjust the appearance of the table by choosing the font and other items. See the Printing Tables topic for a full list of properties that may be adjusted.

Note that when adding or deleting columns Manifold will try to keep the table centered within the table element. Therefore, resizing the table element box may be necessary after adding or deleting columns.

**Editing a Surface for Visual Effect**

Simple editing techniques can be used with surfaces to provide specialized visual effects. In this example we will highlight a band of elevations between 500 and 1000 feet in a surface. Illustrating a specific band of elevations in a surface is often desired for planning presentations. For example, we may wish to show regions in microclimates that are above valley fog but below mountain snows. We will do this by creating an image from the surface, colorizing the image and showing it overlaid upon the surface in a map.

**Step 1: Prepare components to be used**

Import the Montara Mountain surface as described in the Combine a Surface and a Drawing in a Map topic. Use View - Display Options to color it with the **Altitude** palette.

In the project pane, copy the surface and paste it to create a second surface component. Open this copy in a surface window.

**Step 2: Cut out a band from 500 to 1000 feet**

With the surface opened, in the Layers pane turn on the **Background**. Use View - Properties to set the background of the surface to a blue color.
Next, use the **Threshold Lower** transform operator to force all pixels at 500 feet or below to the 500 value.

![Tool Properties](image)

Click on the **Select Touch** tool and in the Tool Properties pane set the tolerance to zero.

![Select Touch](image)

**Shift**-click onto the region of 500 foot elevations to select all such regions in the surface.
We can now choose **Edit - Delete** to delete all pixels at this level, allowing the blue background color to be seen. As can be seen in the illustration above, this is a cool way to achieve "waterline" effects. If we had not turned on the **Background** we would not see the blue background color. [For fun, to see a surface "flood" try using **Threshold Lower** repeatedly with settings of 100, 200, 300 and so on to delete sequential heights of pixels.]

We now run **Threshold Upper** with a setting of 1000 to force all pixels above this level to 1000.
We can then Shift-click into the region of 1000 foot elevations using the Select Touch tool to select all such pixels, and then once more we can use Edit - Delete to delete all such pixels.

What's left is a band of surface pixels that are between 500 feet and 1000 feet.

**Step 3: Create an image**

Since more graphics arts effects can be applied to images than to surfaces we will now make an image from this surface. To do so, launch the Tools - Make Image command.

This saves the surface as the same sized image. When we open the image it will be visually identical to what we saw in the surface window.

**Step 4: Modify the image**

Open the image. It appears the same as the surface.
Using Touch selection, SHIFT-click onto the blue pixels to select all blue pixels in the image. Press Edit - Delete.

This deletes all of the blue pixels in the image.
We will now force all colored pixels to white by using the Image - Adjust - Hue / Saturation command and by turning **Lightness** all the way up.

**Step 4: Show the image in a map with the surface**

We are now ready to use the image in a map with the original Montara Mountain surface.

Create a map with the image in an upper layer and the surface in a lower layer. Right click on the image layer tab and set the opacity of the surface to 50%. It appears as a whitish layer. We would like to accentuate the color of the image to make the position of the band between 500 feet and 1000 feet more obvious.
To do this we click on the image layer in the map and choose the Image - Effects - Colorize command from the main menu. We move the Blue slider all the way to the left and the Red slider all the way to the right. The Green slider is almost all the way to the left. This colorizes the image layer into a red hue. If we do the Colorize operation with the Preview box checked we could interactively try different colors to get the desired effect.

As seen in the illustration above, we've tinted precisely the band of pixels between 500 and 1000 feet.

Notes

Why did we set the background color to blue? We did this so that the image created from the surface has a background of blue pixels. Had we not specified a blue background, the image would have been created with black pixels in the "transparent" regions of the surface. If we would use SHIFT-click to select all black pixels in the surface, this would have selected a few pixels in the deeper shadows within the band of remaining surface pixels. By using a background color that is not at all like any of the colors in the surface we make it easy to select the background color only and not accidentally select any pixels from the remaining surface.

Why did we use an image in a layer to color part of the surface? Could we not have simply altered the Altitude palette used to color the surface so that regions between 500 feet and 1000 feet were colored in red? We could have done that, but using a palette will normally blend colors in between altitude ranges. Using an image as we have done allows us a sharper control over appearance. It also demonstrates how images and surfaces can be combined in maps to achieve desired effects.
Copy and Paste: Image / Table / Drawing

In this example we will copy an image and paste it as a table. We will then copy the table and paste it as a drawing. This topic provides an example for the concepts discussed in the Copy and Paste As topic. If you've jumped here directly from that topic please note that this example uses concepts (such as RGB values) introduced in the Images topics.

**Step 1: Copy an Image**

![](head.png)

Let's begin with a project that contains an RGB image called head.

If we open the head image in a window, we can see it is a small image we have created by cropping our sample bronze image to show just the head of the bronze monument.

If we zoom into this image we can see that like all images it is made up of pixels. Each pixel appears at a given location and consist of color made up of Red, Green and Blue channel values.

To copy this image, we right click on the head component in the project pane and choose Copy from the context menu.

**Step 2: Paste As a Table**

We can then right click in the project pane and choose Paste As - Table from the context menu.
The Paste As Table dialog appears. Because Manifold knows we have copied an image and are now trying to paste it as a table, the dialog is loaded with choices of information that may be extracted from the image for each pixel and pasted into the table as fields. See the Intrinsic Fields in Tables topic for a description of available fields. We choose the Red (I), Green (I) and Blue (I) channel values as well as the Longitude (I) and Latitude (I) fields (scrolled out of sight in the illustration above).

Checking the Longitude (I) and Latitude (I) values indicates we want the position values of the pixels to be extracted as geographic coordinates.

The result of the Paste As - Table operation is a new table in our project called Head 2. The system tries to use a name that is similar to the copied component in a case-insensitive way. Since "Head" is already used in the project the system adds the number 2 to create the new default name.

</tbody>
</table>

If we double click open this table we can see it contains rows with Red (I), Green (I), Blue (I), Longitude (I) and Latitude (I) fields for each row. Each row in the table came from one pixel in the image and contains the various...
field values for that pixel. The **Longitude (I)** and **Latitude (I)** values are the exact longitude and latitude coordinates of these pixels.

**Step 3: Copy the Table**

We will now copy the table. To copy the table, we right click on the **Head 2** component in the project pane and choose **Copy** from the context menu. We can then right click on any empty location in the project pane and choose **Paste As - Drawing**.

**Step 4: Paste As a Drawing**

This launches the **Paste As Drawing** dialog. Manifold knows we have copied a table and are attempting to paste it as a drawing, so the dialog is loaded with choices that make sense for pasting this particular table. Since the table has five fields, those fields are available for pasting into the drawing's table. We will check only the **Red (I)**, **Green (I)**, and **Blue (I)** table fields to paste as fields into the drawing's table.

When pasting a table as a drawing, for coordinates we could use any numeric fields as coordinate fields. Normally the fields used are those that have longitude and latitude values in them. [The option to use any two numeric fields is occasionally used to create a drawing that is, in effect, a scatter diagram of tabular data using two non-geographic data fields as X and Y coordinates.]

By default, if there are numeric fields named "Latitude" and "Longitude" Manifold assumes we would like to use those fields for Latitude and Longitude coordinates and will pre-load the **X / Longitude** and **Y / Latitude** boxes with those field names. In this example our longitude and latitude values are saved in the **Longitude (I)** and **Latitude (I)** fields so we will use them for longitude and latitude.

The result of the **Paste As - Drawing** operation is that a new drawing and its associated table appear in the project pane. As before, to create the name of the new drawing Manifold simply appends a new number to the name of the pasted component if it otherwise duplicates a component name already in use. In this case, the name for the new drawing becomes **Head 3** and the name of its associated table is **Head 3 Table**.
Double clicking open this new drawing shows that pasting the table as a drawing has created a regular array of points. We have formatted these points as small squares and have colored them using thematic formatting so that the color of each point is based on the value of the **Blue (I)** field. Each point came from a row in the table. Each row in the table, of course, came from one pixel in the original image. Each point in this drawing therefore represents a point that was derived from a pixel location in the image.

<table>

</tbody>
</table>

If we click open the **Head 3 Table** table that is associated with this drawing we can see that each record in the table has four fields. The fields are an ID field that links it to a point in the drawing, plus fields the **Red (I)**, **Green (I)** and **Blue (I)** table fields that represent the Red, Green and Blue channel values for the pixels in the original image. Each row in this table is linked to a point in the drawing and represents color data derived (via two **Cut** and **Paste As** operations) from a pixel in the original image.

We can see this is the case by formatting the drawing to increase the size of the square symbols used for points until they merge together at the current zoom level. We can also use thematic formatting to color the points using a range of blue color from dark to very light that is controlled by the content of the **Blue (I)** field.

The result of the formatting applied is to show the drawing (at the current zoom level) as a pixelated rendering similar to the image. The effect disappears as soon as we zoom in or out since it depends upon having the size
of the point symbols fitting together. We use it here not as a replacement for use of images but rather to show how the information content in the original image has been transferred into a regular grid of points.

**Notes**

In the above example we copied an image and pasted it as a table. Having the data content of an image in a table would allow us to use Manifold’s many transform operators for tables to alter the image data in a very free-form way. We could even create active columns in the table that use formulas to compute new values based on the Red, Green and Blue channel values of the image. We could then copy the table and paste it back as an image so that the image's pixels would be colored using the transformed values.

Working with image data in the form of tables will, of course, can be very slow since database tables containing a record for each pixel in an image can be very large. However, it is nice to know that in Manifold one has this option.

The example above shows a table being copied and pasted as an image. This is the normal path for creating an image from a geocoded table. The example shows a usage where a raster image might be converted into a vector data set of points, a “grid” as it is known in some systems. The fastest way to do this, of course, would be to copy the image and to paste it as a drawing.

Note that copying an image and pasting it as a drawing is not the same as vectorizing it to automatically extract points, lines and areas from the image. Pasting an image as a drawing simply takes the position of each pixel and creates a point at that location in a drawing. The drawing’s table can then be loaded with one’s choice of information (channel values, intensity, etc) extracted from the image.

Create a Map from a Geocoded Table  
Create a Geocoded Table from a Map

**Tech Tip**

At times we would like to fetch a component that’s been saved in a .map project file for use in another project file. One way to do this is to open a second instance of Manifold and to open the saved .map project. We can then Copy components from that project file, switch to our current working instance of Manifold and Paste them into our current project.
Painting into the Alpha Channel

The alpha channel of RGBA images controls the transparency of each pixel in the image. Each pixel in an RGBA image has a value from 0 to 255 in the alpha channel that specifies how transparent that pixel should be. A value of 0 means no transparency and a value of 255 means total transparency.

Just like we can turn on and off the R, G and B channels of an image we can also turn the alpha channel on and off. If all the channels of an RGBA image except the alpha channel are turned off, the alpha channel will appear in shades of gray from black to white that show the transparency that will apply in different parts of the image. Because Manifold painting tools apply only to those channels that are enabled, we can enable only the alpha channel and then paint into it using different shades of gray to "paint" different levels of transparency into different parts of the image.

This example explores use of the Paint Bucket and Gradient painting tools used with different colors and different opacity settings to create different transparency effects.

We will use our standard bronze image as an example. The window on the left shows the bronze image in an image window. We have selected all pixels outside the bronze monument and have deleted them. We then used Edit - Select Inverse to invert the selection and thus select only the pixels inside the monument. See the Selection topic for examples of selection techniques.

The window on the right shows a map window open to a map that has two layers: the bronze image on top and underneath our sample schloss image of the Neuschwanstein castle. The schloss image has been colorized to provide a softer visual background for the bronze image on top. We have used the Image - Convert To command to convert the RGB bronze image into an RGBA image.
Throughout this example we will use the Border selection style. The region of selected pixels is outlined in red. We will be working in the image window, as shown on the left. The map window as seen on the right will show the effect of each operation. Each window in Manifold has its own channel settings so we can configure the image window on the left to show only the alpha channel while the map window on the right shows the R, G, B and alpha channels. Channels may be turned on and off in the Layers pane.

We begin by turning the R, G and B channels off in the image window. This leaves only the alpha channel on. The image appears in black since all pixels have a zero alpha value, that is, zero transparency.

**Using the Paint Bucket**

We will now set up our tool controls to use the paint bucket tool.

In the Tools toolbar for images we choose the Paint Bucket tool.

In the Tool Properties pane we choose Opacity of 10.

In the Format toolbar we change the foreground color to white.
Let's consider what the above settings will accomplish. Whatever we pour the paint bucket into, we will be pouring white color with opacity of 10. That means that the white color will pour into pixels with only about 10% of the effect of pure white. If the white color is poured into a region of black pixels, they will lighten by about 10% with each pour of the paint bucket. After ten pours the color should be nearly white. Note that the paint bucket will pour paint only into the region of the image that is selected. All parts of the image outside the selection will be unaffected by the paint bucket.

If we now pour the paint bucket into the black pixels in the image window a few times we see they will lighten into gray color. With each pour of the paint bucket we lighten the gray shade that we see in the alpha channel in the image window. Simultaneously the full RGBA image we see in the map window will become more transparent and more of the schloss image will show through. A lighter shade of gray in the alpha channel indicates a higher alpha value for each pixel, or more transparency.

We can switch the foreground color in the Format toolbar to black. If we now pour the paint bucket (leaving the opacity at 10) it will darken the region of pixels with each pour.

Darkening the shade of gray by pouring darkness into the alpha channel will reduce the transparency of the image. Darker shades in the alpha channel mean less transparency. Less of the schloss image will show through.
Note that we could always have chosen some shade of gray for the foreground color and poured that shade of gray directly into the selected region in the image with opacity set to the default value of 100. Pouring pure black or pure white color with opacity of 10 is an indirect method. It has the advantage of allowing us to pour several times and to adjust the transparency interactively. This indirect, interactive method can be easier than choosing various shades of gray in the color picking dialog until we get the one that provides the transparency we want.

Also note that the alpha transparency takes on the intensity of the color painted into it. We could have selected colors other than black or white (or shades of gray) for the foreground color in the format toolbar and then painted with those colors. If a different color, such as light blue, were poured into the alpha channel it would appear in the alpha channel as the shade of gray that represents the intensity of that light blue color. Because it is difficult for most people to accurately estimate the intensities of colors other than shades of gray it is best to use shades of gray when painting into the alpha channel.

**Using the Gradient Tool**

In the Tools toolbar for images we choose the Gradient tool.

In the Tool Properties pane we choose Opacity of 100. This will allow us to paint the gradients with full opacity. Painting with the gradient tool therefore will totally override the previous colors of the pixels.

We will leave the foreground color black and the background color white. The gradient tool will create a gradient from black to white, beginning with black at the point we begin our click and drag and ending in white at the point where we end our click and drag. All parts of the image beyond the beginning will be solid black and all parts of the image beyond the end will be solid white.

Note that the gradient tool will paint only into the region of the image that is selected. All parts of the image outside the selection will be unaffected by the gradient tool.

In the image window we click where we want the gradient to start and then drag down to where we want the gradient to end and then release. The + cursor shows where we will release.
Examples

Everything before the beginning of the click and drag is painted black and then the gradient transitions from black to white at the point of release. This causes a range of smoothly increasing alpha values in the alpha channel (shown as the smooth transition in gray scale from black to white) that are seen in the map window as smoothly increasing transparency. In the map window we can see that the head and shoulders of the monument are not at all transparent while the lower right regions of the monument are completely transparent. We will leave the selection color enabled in the map window so we can see where the bronze image would be if it were not transparent.

We can click and drag again with the gradient tool to create a transition from black to white over a shorter distance.
The result of the shorter click and drag is a gradient that rapidly changes from black to white. Note that much more of the image in the map window is now fully transparent.

Note also that the pixels have not been deleted (as they might be in the case of invisible pixels) but have simply had their alpha transparency turned up to high transparency values. At any time we can paint different colors into the alpha channel to change the transparency of any of the visible pixels. For example, we could paint a darker color into the alpha channel to lower the transparency and make the pixels less transparent. Or, as seen in the steps above, we could use the gradient tool to paint different gradients into the selected region.

We can use the gradient tool in any direction. In the above screen shot we have clicked at the upper right and dragged down to the lower left.
This results in a gradient being painted into the alpha channel that is dark in the upper right and lighter in the lower left.

Although the above examples have shown the gradient tool being clicked and dragged mostly within the selected area, if desired we can click and drag it in any part of the image. Because the effect of the gradient tool will be seen only within the selected area, we have been clicking and dragging mostly within the selected area in these examples. That makes it possible for the effect of the gradient tool to be easily seen as it is applied to the visible pixels in the monument.

**Edges**

We can use almost any effect or tool we desire on the alpha channel. If we want to restore the alpha channel to no transparency (all black), the easiest way is to simply use the Brightness / Contrast command in the **Image** menu to turn the **Brightness** all the way down to zero.

This has the effect of making all the pixels in the selected region's alpha channel black. This restores the image to zero transparency for all visible pixels.

We can click on the **Selection Style** button to toggle use of red selection color on and off to show the region of selected pixels. If we temporarily turn off selection color, we can see how the image looks. Note that from the map window screen shot on the right we can see that we did a sloppy job of selecting the pixels of the monument, as can be seen by the halo of white edge pixels in the lower part of the monument.
Even if we are careful when selecting pixels within images it is often difficult to avoid some "halo" effect in parts of the image where transitions from dark pixels to light pixels occur. Such transitional regions often contain anti-aliased pixels that help provide a smoother appearance in the context of the entire image but which stand out as unnaturally light when only part of the image is visible.

We will deal with this in a subtle way. First, we turn selection color back on. We then use the Edit - Modify Selection command to create a Border selection using a border that is 2 pixels wide on either side of the previous edge. This takes the edge of existing selection and creates a narrow selection that follows the edge in the given width.

In the screen shots above, if we look closely into the map window we can see that the selection is a ribbon of border that is a few pixels wide that follows the edges of the previous selection. This new selection covers all of the white pixels that were making an ugly halo at the bottom of the monument.

If we were to zoom into the image and use the dense dots selection style to show selected regions, the illustration on the left shows a close-up view of the edge of the selected region in the monument. The view on the right shows the same view after application of the Edit - Modify Selection - Border command with a value of 2 for the border. Normally, the border created would extend two pixels to either side of the previous edge for a total border width of five pixels. Because the edge of the previous selection in this case is bordered by invisible pixels the border ends up being only three pixels wide.
We now use **Brightness / Contrast** once more to make all the pixels in the selection white by increasing the **Brightness**. Making all the pixels in the selection white makes them completely transparent. This gets rid of the halo pixels as can be seen in the map window when we turn off selection color temporarily; however, it also gives the appearance of "cropping" the pixels in the upper part of the bronze monument where there was no halo problem.

The solution to this problem is to use the gradient tool once more. We click in the middle of the image and drag down and release at the bottom. Even though we have temporarily turned off selection color the selection is still there. The gradient tool will work only on that three-pixel wide ribbon of selected pixels that follows the border of the image. The effect of the gradient will cause the upper part of the selected border to be black for zero transparency and the bottom part of the selected border to be white for total transparency.
This creates the effect we want. Note that the image in the map does not show any clipping of pixels about the head of the monument while at the feet there is total transparency so that the halo white pixels do not show because they are completely transparent. If we look very closely at the image window screen shot on the left we can see the gradient in color from black to gray to white in the thin ribbon of pixels at the border of the image.

To see the gradient effect in the border, we can use Edit - Select Inverse once more to select all pixels except those previously selected in the border region. This selects all pixels outside the thin border selection. We can then use Brightness / Contrast to increase the brightness of all these pixels to full white. This will make all pixels completely transparent except those pixels that were in the border selection. This allows us to see the gradient from black to white in the image window at left and the resulting effect at in the map window at right.

There are, of course, different ways of dealing with “halo” pixels than the above. We used the gradient and transparency because in this particular image the halo problem existed only in one region of the image.

Images and Channels
Create a Circular Feathered Image

We would sometimes like to create a circular region of an RGBA image where the region "feathers" from an opaque image to complete transparency. This procedure shows how to apply RGBA pixel transparency through desired parts of an image.

**Step 1: Import the Sample Bronze Image**

We will use the sample bronze image used throughout this documentation. Create a new project with File - New and import the image with File - Import - Image.

**Step 2: Copy the Sample Bronze Image**

Right click on bronze in the project and choose Copy. Right click in any blank region of the project pane and choose Paste As - Image. This creates a new image called Bronze 2.

**Step 3: Open the Bronze 2 Image**

Double click on Bronze 2 to open it in an image window.

**Step 4: Make a Circular Selection**

With selection mode set to Replace Selection, make a circular selection.

The most convenient way of doing this is to use the ALT - Select Circle command to select a circle on center.

**Step 5: Change the Selection to Black Color**
Use **Image - Adjust - Hue / Saturation** to reduce lightness to zero by moving the **Lightness** slider all the way to the left. Because we have a selection, the command operates only on the selection. Reducing the lightness to zero makes all the pixels in the selection black.

**Step 6: Invert the Selection**

Choose **Edit - Select Inverse** to invert the selection. This selects all the pixels *other* than those that were previously selected.

**Step 7: Change the Selection to White Color**

Use **Image - Adjust - Hue / Saturation** to increase lightness to the maximum by moving the **Lightness** slider all the way to the right. Because we have a selection, the command operates only on the selection. Increasing the lightness to the maximum makes all the pixels in the selection white.
Use **Select None** to deselect all pixels. (A one-pixel border has been added to the image above so that the image size is visible against the white background of this help window.)

**Step 8: Apply Gaussian Blur**

Use **Image - Effects - Gaussian Blur** to blur by 30 pixels. The blur will "feather" the edges of the solid black disk into the white pixels using a gradation of color from black to white. This is often used to create shadow effects, but in this case we will use it to create a circular gradient effect.

**Step 9: Convert to Grayscale Image**

We will be using this image as an alpha channel. To use it in a channel, it must be a grayscale image. We use **Image - Convert** to convert it into a grayscale image. There will be no change in the appearance since there are only black, white or gray colors in the image.

**Step 10: Open bronze Image and Convert to RGBA**
Open the bronze image by double clicking on it in the project pane. Use Image - Convert to convert it into an RGBA image. We cannot apply per-pixel transparency unless it is an RGBA image.

**Step 11: Replace the Alpha Channel**

With the focus on the bronze image, we use Edit - Load Mask/Channel to load the image’s alpha channel with Bronze 2. This creates the feathered, circular image. We may now use it as a layer within maps to compose images in multiple layers.

**Discussion**

We can generalize the above procedure to create any number of shapes in black that are then feathered with Gaussian Blur or with other methods and used to guide the alpha channels of RGBA images. Because we started with a copy of the image to be adjusted, any patterns we draw into that copy (that will be used to control the alpha channel) will automatically be lined up with the original image.

We can create unique visual effects by combining feathered images as created above with copies of the original image in maps.
For example, suppose we have made another copy of the original bronze image and then have applied Image - Adjust - Threshold to give it a black and white posterized style.

We could then create a map that has two layers: the threshold bronze image in the lower layer and the feathered circular image in the upper layer. Because the feathered upper layer has a gradient of transparency we achieve a smooth color blend from the surreal threshold image to the real color image.

Manually Georegister an Image

The usual way of georegistering images is to use the automated georegistration tools provided within Manifold. These tools use control points to re-scale, reposition and warp an image to match a known good drawing or image.

In cases where images need not be warped but only need to be re-scaled and repositioned we may use manual registration. This topic illustrates that procedure. It should be read not just to learn about manual methods but also to better understand how the default usage of Orthographic projection applies to images.

When importing images into Manifold we will usually import the image from some format that does not save projection information. Quite likely the image will be provided in .jpg or some other non-geographic format. Images of geographic scenes that are imported from non-geographic formats usually fall into one of four classes:

- Overhead or near-overhead photos. These may be treated for almost all purposes as Orthographic projection. The default usage of Orthographic by Manifold to import such images provides a good basis for use in a geographic context. Such images often may be georegistered simply by changing the origin and scale of the Orthographic projection used to interpret the image's data.
- Snapshots of data sets that are arranged in Latitude / Longitude projection, but which were imaged on computers or saved in formats in a way that the projection information was not captured. Many images found on Internet that show data sets such as ocean temperatures or other data fall into this class. Such images are imported into Manifold as if they were in Orthographic projection. To georegister them we first change their coordinate properties to Latitude / Longitude projection so Manifold correctly interprets their contents in a geographic context.
- Images that are irregularly scaled or warped so that they are neither Orthographic or Latitude / Longitude. Scanned images of paper maps that are in some other projection fall into this class. Such images require the use of Manifold's automated georegistration tools for use within geographic contexts.
- Less frequently, one encounters images saved in a format that does not automatically provide projection information but for which projection information is precisely known. For example, AVHRR images of the US are often encountered as images that have been massaged into Lambert Azimuthal Equal Area projection with known characteristics. Manually setting the projection parameters for the image's properties often is the only step required to georegister such images.

This example provides an instance of the second class of image: a Latitude / Longitude data set that was published as a simple .jpg image.

Our task is to take the globe.jpg sample image and to georegister it to a Latitude / Longitude drawing of world boundaries.

**Step 1: Create a drawing of world boundaries**

Next we import the World_eg.mfd sample drawing (called world in this example for brevity). We open the drawing and use Boundaries in the transform toolbar to create boundary lines on the peripheries of areas shown in the world drawing. While the newly created boundary lines are selected, we Edit - Cut them out of the world drawing. While the focus is still on the world drawing window, we use File - Create - Drawing to create a new, blank drawing in the project pane that shares the Latitude / Longitude projection of the world drawing. We rename this new drawing world_boundaries and double click it open. We can then Edit - Paste the previously cut boundary lines into the world_boundaries drawing. Press Zoom to Fit to see the lines in the drawing [the blank drawing is initially opened at such a high zoom level that we are looking into a blank spot between the newly pasted lines].
Step 2: Create the map to be used.

We create a map using world_boundaries and open the map. Drag and drop the globe image from the project pane into the map window.

The illustration above shows the situation just after we drop globe into the map window [the map is panned and zoomed so that only part of the contents are visible]. The map was created using world_boundaries so it is in Latitude / Longitude projection as is world_boundaries.

A Digression

Let's take a quick digression from our example for educational purposes.

Images imported from non-geographic formats like .jpg are brought into Manifold using Orthographic projection using one meter per pixel with the lower left corner at 0,0. When dropped into a geographic map the 0,0 coordinate is located at the intersection of the Prime Meridian (0 longitude) and the Equator (0 latitude). The image is in the map shown above but it is far too small to be visible at the zoom range shown. To show the spot where the globe image is located, we have drawn a series of red circles at the 0,0 intersection of the Equator and the Prime Meridian. These have been drawn in a layer called circles.
We can zoom farther into the 0,0 location.

If we zoom extremely far into the map at the 0,0 location we will see a dot where the globe image is located.

We don't need to zoom in to see where the image is located when it is imported by default. Understanding how images are imported by default into a projection context will help dealing with images in a more sophisticated fashion.

**Step 3: Change properties to Latitude / Longitude projection**

The native projection of the globe image is Orthographic. Although the globe image is imported into Manifold using Orthographic projection like all .jpg images, it is clear from the "unrolled cylinder" appearance of the image that it is intended to represent raster data shown in a Latitude / Longitude projection. To match the image to the world_boundaries map we need to tell Manifold to treat this as a Latitude / Longitude projection and not as an Orthographic data set.

To change the way Manifold interprets this data we open the globe image in its own window and then use the Edit - Assign Projection dialog and change the projection from Orthographic to Latitude / Longitude. We can then close the globe image window.
We leave the other parameters at their defaults for the time being. Changing coordinates properties in this way makes no change to the data inside the image. It simply tells Manifold to treat the data differently.

The result as seen above in the map window is to greatly expand the globe image relative to the size of the world_boundaries drawing. The drawing appears much larger because pixel coordinates that were once meant to be interpreted as X,Y coordinates in meters are now interpreted as X,Y coordinates in degrees. Because a degree is vastly larger than a meter, the image has expanded in size from a tiny dot a few hundred meters in width off the coast of Africa to something that is hundreds of degrees wide.

If we right click on the globe layer and choose Register, we can see the settings in use in the Register dialog. Note that X and Y unit of measure is Degree. These were the default settings for units when we changed projection in the Edit - Assign Projection dialog and they result in each pixel being treated as if it were one degree in size.

**Step 4: Re-scale the image using the Register dialog**
We need to reduce the size of the globe image by changing the scale specified by the X and Y settings for Local scale.

When rescaling images manually, we can check the Preview box and then change Local scale settings through trial and error, or we can make a first guess based on observation or information we might have about the image. If we look at the map screen shot above, it appears that the image is about three times larger than it should be. We can try to reduce the scale threefold.

If we change the Local scale values for X and Y to 0.333333 as shown above to reduce the scale to one third, the image will be reduced in size threefold. It turns out that this is a good match.

Making the above changes in the Register dialog will have the result shown above in the map window. The globe image now appears to be about the same size as the world_boundaries drawing. We can zoom in to see the alignment of the data sets better.

**Step 5: Move the image to align it with the data set.**

The screen shot above shows that the lower left corner of the image is still located at the 0,0 intersection of the Equator and the Prime Meridian. We would like to move the left edge of the image Westward 180 degrees, and we would like to move the bottom edge of the image Southward 90 degrees.
We can do this by changing the Local offset values for X and Y in the Register dialog. Right click on the globe layer tab and choose Register. With Preview on, we can change the X value for Local offset to move the image left and right horizontally. Decrease the X value for Local offset to move the image Westward. It turns out that -180 is the right value.

Seen zoomed in a bit the map shows that the image has been moved to the left 180 degrees when a value of -180 is used for X in Local offset. Although we could have found this value by trial and error, a more experienced user would have seen immediately the number was -180.

We now need to move the image Southward by adjusting the Y value for Local offset. If we want to move the image Southward 90 degrees we will need to change the Y value for Local offset to -90.
Applying these values in the Register dialog will align the globe image with the world_boundaries drawing. Closer inspection will reveal that the image is very well aligned with the drawing except for Antarctica. This is likely an error in the “projection” of the original data set for Antarctic regions.

We can see the close alignment by zooming in to Africa. If desired, we can adjust the image and drawing slightly to provide a more dramatic effect.
To create the above screen shot, we increased the contrast of the globe image slightly to provide a greater contrast between ocean areas and the land areas. We then selected the ocean areas and reduced their brightness to black. See the Selection in Images example for this sequence of steps.

We then changed the formatting in the world_boundaries layer to change the color of lins to bright yellow. We then changed Layer Opacity of the drawing layer to 60%.

Comments

Note that a very close examination of the shores of North Africa in the screen shot above might suggest that the image has been moved too far southward. If we wanted to "nudge" it slightly upwards we could use an Y offset value of -89.5 instead of -90. However, the image in use is a rather low-resolution image and probably does not merit chasing after a perfect georegistration. It's fine for providing an overview presentation.

Images we download from Internet will often be summary images and not the original data. For example, the globe image originated in a very high resolution 1 km data set that was sampled and re-sampled downward in resolution many times. The important thing is that manual registration (or better, use of the georegistration tools in a more automatic way) provides a ready means of using images in a real geographic context.

Manual georegistration of some images, like our Latitude / Longitude example, can become remarkably fast with practice, especially when similar images are to be registered. The process set forth above can be reduced to only two dialogs: one dialog to change to Latitude / Longitude projection and then one use of the Register dialog to change Local scale and Local offset. For simple images, some expert users find this faster than clicking control points and using the automated georegistration tools.

The example above is slightly contrived since we guessed the new scale factor (one third, or 0.333333) right away. In many applications we will have to choose a scale factor by trial and error to get close to the right factor. We will then shift the image through Local offset and then once again change the Local scale once the image is closer to final alignment and adjustments in scale can be better seen.

Could we have used more 3's or fewer 3's after the decimal point for Local scale, so that we could have had values like 0.33 or 0.3333333333? Yes, of course. This particular sample image is a low precision image suitable for presentation purposes and not intended for real science, so the choice of six 3's of precision was purely arbitrary.

Other Options

An equivalent way to achieve the same effect as the example above is to scale and shift the internal coordinate system of the image in one step using the Projection dialog as follows:

- Create the map as set forth in Steps 1 and 2 above.
• Open the map in a window so the effect of changes can be seen.
• Open the image in an image window.
• Use the Edit - Assign Projection dialog to change projection to Latitude / Longitude.
• Change the Local offset values to -180 for X and -90 for Y.
• Change the Local scale values to 0.333333 for both X and Y.

We can use the projection dialog when we know in advance what scale and offset is to be applied to a given image. This is useful when registering a series of similar images.

See the Edit - Change Projection topic for a discussion of the Local scale and Local offset options and their relationship to traditional scale correction, false easting and false northing values.

Another way of georegistering the image is to use control points as discussed in georegistration.

We can use the Control Points pane to place control points in the World drawing and at equivalent positions in the Globe image, we can then use the Register button in the control points pane to register the Globe image to the World drawing.

The Simple method is equivalent to changing Local offset and Local scale.

Examples

For fine adjustment of registration, use the layer repositioning commands.
Image Effects in Maps

Combining images with drawings in maps can lead to spectacular presentation graphics. Image effects allow a wide range of graphics arts effects when combined with drawings. This topic creates a presentation map using editing in drawings, drop shadows created with Gaussian blur, and a color gradient applied to an image.

**Step 1: Prepare drawing**

Import US_Main and create a drawing using the procedures given in the Create a Projected US Map topic.

Open the drawing in a drawing window. We will use Smart Mouse Selection and drawing editing to move states around. Make sure the mouse is not occupied with a command mode (such as Zoom or some other mode) and click on the state of Washington.

The state becomes selected as the primary selected object, ready for editing, with edit handles appearing. Edit handles overlap densely at the zoom level illustrated. Click on any of the edit handles and drag to the upper left.
Clicking and dragging an edit handle moves the entire object to the upper left.

Release the click and drag and the state of Washington snaps to its new location.

Click on the state of Oregon to select it for editing and then click on any edit handle and drag it to the left.
Release the click and drag and Oregon will move to its new location.

Continue in this way to move western states away from the main part of the drawing. Save the project as a .map. It is always wise to save work in a project against the chance of irreversible user errors.

**Step 2: Create a Drop Shadow**

We will now create a "drop shadow" for this rendering of the United States. A drop shadow is a graphics layer that gives the appearance of a shadow, as if the item above it were physically suspended above the page and casting a shadow. To create a drop shadow we begin by saving the drawing as an image.

Choose Tools - Make Image command, saving the image using the name "Shadow Mask." We've picked a name that sound a bit strange for now, but it will make sense later.

The default size of the image will be that seen for the drawing at display monitor resolution. Choosing the image size at this stage of our procedure will affect the quality (resolution) of the drop shadow. If the map we are creating will be printed out on a large scale we may wish to use a much higher resolution image. To do so we could first create a print layout for the drawing and then use the Make Image command for the layout (when used with layouts the Make Image command allows specification of image resolution).
The result is an image called **Shadow Mask**. We open this image in an image window and see it is an image that is 1200 by 900 pixels in size that is a raster image rendering of the drawing we had created. It appears with blurry border lines in the illustration above because the view is zoomed out to enable the image to be seen at reasonable size in this topic.

We have zoomed out far enough so the extent of the image is clear. Beyond the edge of the image we see the default, "transparent" background. Note that when Manifold created the image from the drawing it used the background color, white, to fill in the "empty" white space around the area objects.

We will use this image to create a drop shadow. However, because the blue regions from the area objects press right up to the edges of the image we first need to add margin to the image to provide a larger image into which the Gaussian blur can reach.

We add margin using the Transform toolbar and the Add Margin operator. As seen above, we will add 100 pixels to the margin.
The result is a 100 pixel margin added in black color. To make the black margin match the rest of the image we will use the Paint Bucket tool to fill it with white color.

Click on the foreground color in the format toolbar for images and make it white (the illustration shows both foreground and background color wells in white color).

Click on the paint bucket tool and then click anywhere in the black margin.
The paint bucket tool will fill the region of contiguous black pixels with white color.

Our next task is to make all pixels in the blue map region black in color. We need to select all pixels that are not white.

The easiest way to do this is with Select Touch and SHIFT clicking onto any of the white pixels. This selects all of the white pixels in the image. We use SHIFT to extend the touch selection to all white pixels and not just those that are contiguous to the pixel on which we clicked. Had we not used SHIFT there might have been some white pixels in the Great Lakes or the upper parts of Chesapeake Bay or other enclosed regions that would not have been selected.
To select all non-white pixels we simply choose Edit - Select Inverse to invert the selection. It would have been difficult to select all non-white pixels using touch selection because they are a mixture of blue and gray colors. In this case it was much easier to select the white pixels and the invert the selection.

We launch Hue / Saturation and move the Lightness slider all the way to the left to force all of the selected pixels to black. Press OK.

The result (seen after pressing Select None so there is no selection) is that all of the non-white pixels have been converted to black color.

We can now create a Gaussian blur shadow by choosing Gaussian Blur. The number of pixels used for the blur depends upon the shadow effect desired and the resolution (size of the image in pixels) of the image. Using larger numbers of pixels results in larger "shadows." Large and faint shadows can provide a visual cue that the object is "floating" farther away from its background. Smaller and dark shadows indicate the object is closer to its background.

Beginners might want to experiment with Preview checked to see the effect obtained.
The result is a blurred image of the black pixel regions. The astute reader may have already thought ahead to how this might be used as a layer under a vector drawing layer to create the impression of a shadow.

**Step 3: Create a map using a shadow image**

To use a shadow image under a drawing layer we need to work with a map, because only maps in Manifold have layer structure as we would like to use. We use the US_Main drawing to create a map. We then open the map. Because we will need the Shadow Mask image for other purposes, we will first Copy the Shadow Mask image in the project pane and Paste to create a second image that we call Shadow.

We drag and drop the Shadow image into the map, right click on the Shadow tab and choose Order to move it below the US_Main layer. The illustration above shows the tab separately from the illustration of the map to
provide a more compact illustration. Note that the image is correctly georegistered to the drawing. It was originally created from the drawing and so continues to be georegistered to the drawing. However, the blur effect is not what we would like. To create a drop shadow effect the image should be displaced from the drawing.

To offset the drawing from the shadow we click on the **US_Main** layer to make it active.

Using the **Grabber** tool, we do a CTRL-click-and-drag slightly to the upper left. This moves the drawing relative to the drop shadow. We could have clicked on the **Shadow** layer and used CTRL-click and drag slightly down and to the right to move the shadow instead of moving the drawing. The visual effect obtained would be the same. Note: moving layers with a CTRL-grabber works only if the layer and the map both use the same projections, differing only in local offset or local scales.

At this point, the drop shadow effect is achieved for many purposes. If desired, we can right click on the **Shadow** layer and choose **Opacity** to alter the opacity of the shadow layer. Altering the opacity of a layer bearing a drop shadow will alter the lightness of the shadow and can provide a more realistic effect.
However, there is a problem with the map we have constructed that unchecking the Background box in the Layers pane reveals. With the background turned off we can see all layers against the checkerboard default background. In particular, we can see that the Shadow image has a large region of white pixels. The shadow is constructed in that image by blending black pixels in a Gaussian blur into a field of white pixels. That's fine for an effect if we desire a white background and if the Shadow layer is to be the lowest layer in our map.

**Step 4: Create a drop shadow using alpha transparency**

Suppose, though, we would like another drawing layer to appear below the US_Main layer and its shadow, so that the United States appear to float above another drawing and to cast a shadow on that layer? In that case, the shadow layer must be constructed so that the black shadow blurs or “feathers” into transparency, not into white pixels. This is an effect that can be achieved using a short sequence of sophisticated steps.

First, we open the Shadow Mask image in its own window. We then use Image - Convert To to convert it into a Grayscale image. We then close the Shadow Mask image.

Next, we open the Shadow image in its own window. We use Image - Convert To to convert it into an RGBA image.

With the focus on the Shadow image window, we launch Hue / Saturation and move the Lightness slider all the way to the left to force all of the pixels in the image to black. We leave this image window open because we have one more command to apply to the image.
We can see the effect of forcing all of the pixels in the **Shadow** image to black. It seems very counterproductive since it destroys the shadow effect.

With the focus on the **Shadow** image window we choose Edit - Load Mask/Channel.

![Load Mask/Channel dialog](image)

In the **Load Mask/Channel** dialog we load the **alpha** channel using the **Shadow Mask** image. This is why we named it "shadow mask" when it was created and why we converted it to a grayscale image. Only grayscale images can be used as masks. Because we created the **Shadow** image from the **Shadow Mask** image both are exactly the same size and thus the **Shadow Mask** can be used as a mask. Remember that the **Shadow Mask** image shows a Gaussian blur drop shadow in shades from black to white. If we use this as a mask for the alpha (transparency) channel of an **RGBA** image we will be superimposing a transparency gradient upon the **Shadow** image that follows exactly the pattern of the Gaussian blur in the **Shadow Mask** image. Applying such a transparency gradient to the all black **Shadow** image will result in a gradient from solid black pixels to fully transparent pixels with partial transparency in the region of the Gaussian blur effect. We will have achieved a blur from black into transparency.
The moment we press OK in the Load Mask / Channel dialog we can see the effect in the map window. There is no longer any solid appearance to the Shadow layer in any location other than the actual shadow. We can now create layers under the Shadow layer and they will show through as desired.

**Step 5: Add a graticule**

To show the effect of the transparent drop shadow we can add a graticule underneath the US_Main and Shadow layers.

Right click the US_Main layer tab in the drawing and choose Add - Drawing to add a drawing. Name it Graticule.

In the Tools - Options - Colors dialog change the graticule color to black.

Choose View - Graticule to launch the Graticule dialog. Use the settings shown above and push Create to create a graticule as line objects in the Graticule drawing layer.
The result is a graticule grid that appears in the layer. We can right click on the layer tab and choose **Order** to move the layer tab to the bottom of the layer stack.

To achieve a lighter shadow effect, we right click on the **Shadow** layer and choose **Opacity**. In the **Opacity** dialog we set the transparency of the layer to **50** percent and press **OK**.

The result is a map using a transparent drop shadow that allows layers beneath it to show through. Note how the partially transparent shadow produces a natural effect where it overlays the graticule lines.

**Step 6: Add a gradient color effect**
A combination of images and drawings in maps can create many effects in addition to drop shadows. For example, we can color the US using a gradient of color. [This example shows a purely artistic effect. If we want to show data as gradients we could use surfaces.]

To create the effect desired we need to create another image from US\_main. We do this by opening the US\_Main drawing in its own drawing window and then choosing Tools - Make Image as we did before.

We will create an image called Gradient.

If we click open the Gradient image in its own window we can see that it is similar to the Shadow Mask image we created to use in building a drop shadow.
Using the **Select Touch** tool we **SHIFT**-click on the white pixels to select all white pixels.

Press **Delete** to delete the white pixels. We now need to select the other pixels. To do this, we **SHIFT**-click onto the region of invisible pixels and then choose **Edit - Select Inverse** to invert the selection. The result is to select all of the remaining, visible pixels.

To create a color gradient we choose the colors in the format toolbar foreground and background colors that will define the gradient.

Select the gradient tool.
Create a gradient by clicking on the left side of the image with the gradient tool and then dragging to the right side and releasing. The color gradient will be created along this line within the selected pixels.

Instantly, we achieve a dramatic coloring effect in the Gradient image.
If we drag and drop the Gradient image into our map as the uppermost layer we see the dramatic effect in the map as well. Because the Gradient image was created from the US_Main drawing it is georegistered to that drawing and overlays it perfectly.

We may want to show borders for states in the composite map. To do this we must create a drawing layer of state boundaries above the Gradient layer.

Click on the US_Main layer and run the transform toolbar using the Boundaries operator.

This creates line objects in the US_Main layer that outline the boundaries of the state areas. We can cut these out of the drawing using CTRL-X or Edit - Cut. We can then right click onto the Gradient layer and choose Add - Drawing to create a new drawing. We can then paste the boundaries into the new layer with CTRL-V or Edit - Paste.
The final result is a dramatic map that was created using a mixture of image and drawing techniques.

**Comments**

The images used in this procedure are slightly larger than necessary because the initial size of **1200 x 800** used in the Make Image dialog results in unnecessarily large borders around parts of the image. We could have reduced the size of the images by using Crop after creating the Gaussian blur.

It is usually better to create a drop shadow effect by repositioning the layer containing the drop shadow than it is to move the objects being shadowed as was done in this example.

The map shown uses a gradient image at the end to color the states of the US. If desired, this step could be skipped and the "blue" drawing thematically formatted. Moving the states to new positions for artistic effect does not change their status as objects: they can still be thematically formatted to show trends in population or other variables.

The planned use of the map should be considered when specifying the size of the drop shadow created using Gaussian blur. A blur of **30** pixels as used in this example works well when a large image is seen in a zoomed out view as a small portion of the monitor. Using a blur much smaller than that would result in a too-thin shadow. However, when zooming into the view or printing on a larger sheet of paper 30 pixels of blur may prove too much. Experience will reduce the need for trial and error.

While gaining experience, make a copy of the black and white image and then apply Gaussian blur to the copy. One can then relatively easily fall back and use a different level of blur if the original effect proves disappointing. Changing the perceived blur in the shadow used in the map is easy, since once we create a new Gaussian blur mask we simply re-load the alpha channel with the new mask.
Create a Globe Image

In this example we create the image seen above. The task is to take a georeferenced globe image, re-project it into Orthographic projection and then add haze near the edges.

**Step 1: Prepare the base image**

We begin by using the methods described in Manually Georegistering an Image to georegister the globe image. We alter the contrast as described in Selection in Images and apply Relief to better highlight mountainous areas.

Next, we show the image in a map and re-project the map into Orthographic projection using **Edit - Assign Projection**. Click the **Suggest** button for reasonable values in the map projection. The map shows a georegistered image seen within a projected map. This is great for applying projections and other geographic effects but it involves a lot of computation overhead if we are doing only graphics arts work and don't care about projections or preserving geographic context.

Note: if we wanted to re-project the original image, we would use **Edit - Change Projection**. In that case, it is very important to use the **suggest** button to get sensible values for local scale, which should be the same.

Because we are interested in using this image for purely graphics arts work, we will take a moment to save it as an image. To do this, we use the **Tools - Make Image** command to save the component as image at screen resolution.
Examples

Clicked open in an image window the result is seen above. It is a nice image but lacks a sense of presence because there is no haze that appears near the edges. We will use the earth image in a map together with other image layers to create a more artistic effect.

**Step 2: Create the haze layer mask**

We will be working in a map window, so we create a map using the earth image. We will call the map earth_from_space. Next, we need to create the image layers that will modify the appearance of the earth layer. We begin with a haze layer.

To create the haze layer, we will first create a mask that will be used to apply variable transparency.

In the project pane, right click onto the earth image and choose Copy. Right click elsewhere in the project pane and choose Paste. This makes a copy of the earth image. Name this copy hazemask. Double-click open the hazemask image.

Touch select the white areas in the outer part of the image.

Next, choose Edit - Select Inverse to invert the selection. This is a quick way of selecting just those pixels that make up the planet in the image. We use Image - Adjust - Hue / Saturation to reduce Lightness all the way to the left. This makes all the pixels in the planet region black.
We now apply Gaussian Blur to blur the edges. The image above shows the effect after we have applied it and have chosen Select None to clear the selection. Note that since only the region of pixels showing the planet was selected the Gaussian blur effect is blurry inward only. [A nuance: even though the Gaussian Blur effect works within the selected region only, it computes its effect globally based on pixels outside of the selection as well. The image should be large enough so that the region of white pixels outside the selected area is reasonably large all the way around the planet’s disk. If the image is cropped so there are few white pixels except in the corners of the region, then there will be a visible difference in the Gaussian blur effect along the edges where there are fewer white pixels outside the selection.]

We then apply Invert to invert black and white values. We use Image - Convert To once more to convert the image to a Grayscale image (because masks must be grayscale). We can now use hazemask as a mask.

**Step 3: Create a haze layer image and apply the mask**

Once more we copy the earth image in the project pane and paste it as a new image in the project pane. Name this new image haze.

Open the haze image in an image window. So far, it is a copy of the earth image. Use Image - Adjust - Hue / Saturation to increase the Lightness to full. This makes the entire images white pixels.

Now we used Edit - Load Mask/Channel to load the alpha channel from hazemask. The result in the haze image is shown above. The central part of the haze image is completely transparent and the outer part is completely opaque white. The transition region from completely transparent to completely white is that part of the hazemask image that was blurred using Gaussian blur.
We can now drag and drop the `haze` image into our `earth_from_space` map as a layer above the `earth` layer. The result is seen above. The transparent central parts of the `haze` image allow the `earth` image underneath to be visible. The gradient from transparent to white creates a haze effect at the edges of the planet region.

**Step 4: Create a "background" layer**

If we want a white surrounding color we are done. However, if we wish to have a different color surrounding the "planet" we will need to add one more layer. This new layer will overlay the layers already created, but because it will be precisely shaped with a "hole" in the center for the planet it will appear to be a background.

We do this by going back to the project pane and once more copying the `earth` image and pasting it as a new image, which we shall call `space`. So far, `space` is an exact copy of the `earth` image.

We open the `space` image and touch select the white areas in the outer part of the image.
Next, we choose Edit - Select Inverse to invert the selection. We want to select a region just one or two pixels smaller than the "planet", so we use Edit - Modify Selection - Contract and contract the selection by 1 pixel. [This is a matter of taste. Under some circumstances we might use 2 pixels.] We then choose Edit - Delete to remove the pixels in the selection by converting them to invisible pixels.

Next, we use Image - Adjust - Hue / Saturation to reduce Lightness all the way so that all the pixels become black. The result is illustrated above. Finally, we apply Image - Effects - Gaussian Blur set to blur 2 or so pixels. The result is a black image with a circular region that is a pixel smaller than the planet region with a slight blur right at the edge. We drag and drop the space image thus created from the project pane into the earth_from_space image.
In the earth_from_space map window we can now right click on the space layer tab and set the layer’s Layer Opacity to achieve the color we like for what appears to be the background. Layer opacity in the 80% to 90% range results in effects as seen above.

Notes

One of the main techniques shown here is copying an original image and pasting it as a series of images that are then in turn transformed into masks and other layers. Using the original image and then creating the masks from copies of that image guarantees that the masks and space layer will be exactly the right size to use as we desire in layers in combination with the original image.

Why did we go to the effort of contracting the selection and applying a Gaussian blur when creating the space image? If we were to simply select the planet region and make it invisible in the space layer we would end up with the "jaggies" when the space layer was placed above the haze and earth layers. The harsh transition between invisible pixels and solid black pixels in the space layer would result in a jagged edge. By making the "hole" a pixel or two smaller in size than the planet disk and applying a Gaussian blur we end up with a slight transition from invisible pixels to solid black pixels. The effect is something of a manually created anti-aliasing that gets rid of the jaggies. Using a blur in a zone a few pixels wide is a good way of making transitions in images.

Strictly speaking, only the haze and space images need to be RGBA images. The earth image could be an RGB image.

It's important to understand that except for Step 1 this entire topic is about graphics arts work using images in a non-geographic way. Only in the first step do we use the images in a geographic context to create a view of the Earth in Orthographic projection. We then make an image that is a screen shot of that view. After that, all work is done on the screen shot image and not with the original georegistered image / map.

We could have combined drawings with the image in the original map from which the original screen shot was made. In that case, the earth image with which we started could have included visual effects from drawing, like the last image in the Manually Georegister an Image topic.

Just for fun, we can go back to the original geographic map and create an Orthographic projection that is centered on 0 longitude and 90 latitude for a polar aspect view. We can then make a screen shot image and process that image as noted above to create a polar aspect view from space, with haze.
Import a Shapefile

"Shapefiles" are GIS files in ESRI's .shp format. In this example we find a map on the Internet, download it, import it into Manifold as a drawing and then correctly set the drawing's coordinate properties. We will import a map of the 109th Congress districts from the USGS's National Atlas of the United States.

When importing shapefiles, if the shapefile is intended to use the default WGS84 datum and is also in latitude / longitude unprojected form then import is easy: we simply import the file using the File - Import - Drawing dialog and we're done. This example uses a slightly more sophisticated example, where the shapefile is in latitude / longitude unprojected form but using a datum other than WGS84. In this case, we do the simple import but then after import we must correct the datum from WGS84 (the default) to the desired datum.

All URLs given below were current at the time this topic was written. Since web pages change continually it is quite likely the pages given have changed.

Step 1: Locate and download the shapefiles

Visit the National Atlas Map Layers Warehouse page at http://www.nationalatlas.gov/atlasftp.html, and drill down into the site to find the 109th Congress districts layer.

We download the cgd109p020.tar.gz shapefile. Note that the data set is available in both shapefile format and SDTS format. The SDTS format is more precise because it automatically captures projection information that shapefile format does not save. However, since this example illustrates how to get around various hassles involved in using shapefiles we will go ahead and download the shapefile version.

Step 2: Find and download accompanying documentation

As experienced hunters of shapefiles, we know that we should never download a shapefile from a website without also trying to locate and download any accompanying documentation. We see that the September 2005 link appears in a column that seems so have something to do with metadata, so we click on the link. It leads to a page with lots of information including links to "spatial" metadata, which is usually where information about projections is located. After hunting around a bit we find:

b. What coordinate system is used to represent geographic features?

Horizontal positions are specified in geographic coordinates, that is, latitude and longitude. Latitudes are given to the nearest 0.0000278. Longitudes are given to the nearest 0.000278. Latitude and longitude values are specified in Decimal degrees.

The horizontal datum used is North American Datum of 1983.
The ellipsoid used is GRS1980.
The semi-major axis of the ellipsoid used is 6378137.
The flattening of the ellipsoid used is 1/298.257222.

Because the geographic coordinates are in decimal degrees we know that the shapefile is in unprojected, Latitude / Longitude form. All we need now is the name of the Datum, which we can see is the North American Datum of 1983 using the GRS1980 ellipsoid.

Many people use "datum" as a synonym for "ellipsoid" although the two are not exactly the same. Usually a named datum such as the North American Datum of 1983 automatically implies the use of a particular ellipsoid so that to specify both is somewhat redundant. In general, use the name of the datum if you can find it in the Manifold projection dialogs. If you can't use the name of the ellipsoid if you can find that. Note that there is some variation in how the names of datums and ellipsoids are abbreviated. For example, people write this ellipsoid's abbreviation as either "GRS1980" or "GRS80".
Examples

Because this example deals with the simple mechanics of importing a shapefile we state that the only data we need from the documentation is the projection information (types of coordinates / projection and datum and/or ellipsoid). The documentation also includes much other useful information such as the provenance of the data, accuracy and so on that could be very important later should we wish to document the sources and nature of our data.

**Step 3: Decompress / De-archive the download file**

The actual file downloaded is called `cgd109p020.tar.gz`. In the usual Federal way, this file employs a compression and archiving technique that is not used by 95% of computing humanity. It uses GNU-zip ("gz") compression applied to a UNIX tape archive ("tar") file. Lucky for us, mighty WinZip can deal with such weirdness.

**Very Important**: Before using WinZip to extract any files with a "tar" in the extension, make sure that WinZip’s Options - Configuration - Miscellaneous tab has the TAR file smart CR/LF conversion box NOT checked. This box is there so WinZip can convert UNIX style text files to DOS style text files if they are archived as tar archives; however, if WinZip applies the same conversion to binary files (like shapefiles or other GIS binary files) saved in tar archives it will ruin them.

![File List]

After using WinZip to extract the files we can see we have created four new files (seen above in Windows Explorer): a `.txt` file and the three files that make up the "shapefile": `.shp`, `.dbf` and `.shx` files. It turns out the `.txt` file contains a copy of the metadata we saw in the web site link. USGS has thoughtfully included this with the shapefiles because they know that shapefiles do not save projection information. However, we did not know that such a text file accompanied the shapefiles so it was wise of us in the previous step to hunt down the documentation for the shapefile, just in case. Most shapefiles found on the web will consist simply of the `.shp`, `.dbf` and `.shx` files that are part of the actual shapefile format.

**Step 4: Import into Manifold**

Launch Manifold and use File - Import - Drawing to import the `cgd109p020.shp` file as a drawing.
In the **Import** dialog use the **SHP Files** setting in the **Files of type** box.

In the next dialog, we see all the fields available for import from this shapefile. We use the default with all fields checked and press **OK**.
A new drawing appears in the project pane, complete with a table.

The districts show the exquisitely drawn, bizarre shapes designed to aggregate voting majorities of the party in power in a state and to deny the opposing party the opportunity to ever form a majority. If we clicked open the table associated with this drawing we would see that for each area object there is a record providing various attributes for that congressional district such as the name of the representative and other information.

Note that the information bar advises us the projection has not yet been verified and invites us to click on the bar to do so.

**Step 5: Provide corrected datum**

It would appear at first glance that the drawing imported correctly. If we pass the mouse over the drawing we see apparently correct latitude and longitude figures for the mouse's position. The shape of the United States has the familiar rectangular appearance of the US seen in unprojected Latitude / Longitude form. If all we will use this drawing for is thematic formatting to present information (such as a thematic overview of which districts are Republican and which are Democrat) we could use this map "as is."

However, because the default datum used when importing shapefiles is **WGS84** and not the North American Datum of 1983 for maximum precision we should change the datum to that actually intended for the shapefile used. This will give as precise as possible a spatial match between this drawing and any other drawings we might use with it in a map.

To change the datum we click on the information bar to open the Edit - Assign Projection dialog.
The datum box is loaded with the default datum used on shapefile import.

To change this, we scroll through the choice of datums conveniently organized into one massive list of seemingly endless datums until we reach the North American 1983 (mean for CONUS) datum. In a rare lapse of precision, USGS refers to the "North American Datum of 1983" in the metadata text file for the congressional districts shapefile we downloaded. However, there are in fact several different North American datums for 1983. We choose the one for "CONUS" (Contiguous US). We don't know for sure this is the datum intended by USGS, but it is the best bet given the information we have and considering that most of the congressional districts are located within "CONUS".

We press OK to apply this projection interpretation to the coordinate properties of this drawing.

Except for the disappearance of the info bar advising us to verify the projection, there is no change in the visual appearance of the drawing since any change caused by a difference between the World Geodetic datum used by default and the North American datum we specified is completely invisible. In fact, it is so small it is likely to be less than the intrinsic accuracy of the shapefile as drawn by USGS.

Note see the Import Drawing - SHP, Shapefiles topic for an example of importing a projected shapefile where more than just the datum is changed. Also, see the Import a Projected Shapefile Example.

At this point we have accomplished what we set out to do, importing a shapefile into Manifold. The rest of this example shows some elementary, optional steps illustrating typical tasks such as thematic formatting and re-projection.

**Step 6: Apply thematic formatting**

Our drawing looks boring in gray and does not convey all of the information that is in the drawing's table. We can show information in the table by using thematic formatting to color the areas in the drawing based upon the data associated with each area.

Let's have fun and color the drawing by political affiliation. We click on the background color well for areas in the Format Toolbar and choose Theme... in the pull-down menu of colors.
We set up the **Format** dialog as shown above. We changed the colors in the color wells by clicking on them and choosing a desired color. The party affiliation codes are either **D** or **R** for Democrat or Republican and **I** for Independent. To avoid hackneyed stereotypes, we’ve chosen colors other than the “blue state” and “red state” convention often used in the US.

Alert readers will notice that the number of representatives adds up to a higher number than there are seats in Congress. The numbers are higher because this is the number of areas in the map coded for each party: some congressional districts (such as those that contain islands or water areas) are represented by multiple area objects.

The drawing now shows congressional district colored by party affiliation. Some regions in gray are areas over water in the Great Lakes and not assigned to a particular district.
If we zoom out, we can see how congressional districts of the two parties are distributed across the United States.

**Step 6: Project the drawing**

Zoomed out to see the entire lower 48 states of the United States the drawing has an unpleasant, "flattened" appearance caused by the use of *Latitude / Longitude* coordinates. We can give the drawing a more pleasant appearance by either displaying it within a map that uses a projection or by re-projecting the drawing into some appropriate projection. This is a purely optional step motivated by nothing except a desire to have a more appealing visual appearance.

We can project the drawing using the Edit - Change Projection command and choose a projection desired, such as the Lambert Conformal Conic projection using *Center* numbers that are a position roughly in the center of the US.

This dialog is essentially identical to the projection dialog used within Edit - Assign Projection. However, whereas the Edit - Assign Projection version does not change the data (it simply tells Manifold how to interpret the coordinates that exist), the Edit - Change Projection dialog will re-compute the data in the drawing to new coordinate numbers.
Note that we manually entered the -96 value for the Center Longitude. We did not use the Suggest button (which would be the normal action), because the illustration we have been showing is zoomed into a view that shows only the continental United States; however, the actual drawing contains the entire United States, which includes territory spanning the globe. Alaska, for example includes islands on both sides of the +/-180 longitude line. Pressing the Suggest button would therefore suggest a value of 0 for the Center Longitude because this particular drawing spans the globe.

The result of the re-projection is a classic projected view of the contiguous, lower 48 states of the US. Note that the illustration above is a zoomed in view. Using a conic projection will result in considerable distortion within American Samoa and other regions that are far away from the lower 48 states. However, since our illustration above shows only the lower 48 states we have chosen to use a projection that looks good for that region.

Note also that we chose the "single parallel" version of the Lambert Conformal Conic. This is the easiest to specify because all we need specify are the center latitude and center longitude. It is not as low in distortion as the full Lambert Conformal Conic but for a thematic map of this size we are not worried about distortion. We would rather avoid the (slightly) extra work of specifying two additional parallels to be used.

Regional Settings

When importing data from text file formats like .csv or .dbf or from shapefiles (because shapefiles use .dbf format as part of the shapefiles) the Regional Options in our Windows system have to match settings within the file that is being imported. This is because such simple formats are too stupid to understand that in different countries people use different symbols to denote decimal points (that is, either a dot character or a comma). To change Regional Options in Windows, do the following:

- Go to the Control Panel and open the Regional Options applet.
- Go to the Numbers page,
- Ensure that the Decimal Symbol is set to '.' (dot),
- Ensure that the List Separator Symbol is set to ',' (comma),
- Press Apply to apply changes if there were any,
- Import the .csv file or shapefile desired.
- After import, restore the original settings of Decimal Symbol and List Separator Symbol if you like.

Another option is to invoke the Data Sources applet (hidden within Administrative Tools folder of the Control Panel if you're running Win2K or XP) and create a file DSN for the .csv file you want to import. After creating the DSN configure it to use the comma character as a data separator.

See Also
Import Drawing - SHP, Shapefiles for discussion of shapefile import, including the role of database drivers. This topic also provides an example of importing a \textit{projected} shapefile, including use of the Edit - Assign Projection dialog after the import to adjust projection parameters.

See also the Import a Projected Shapefile topic for a step by step example showing how to import a shapefile that contains projected data.
Import a Projected Shapefile

Because ESRI .shp format files ("shapefiles") do not store projection information they are most often used to save information in unprojected form where the contents are coded in coordinates using values that represent degrees latitude and longitude. On occasion we may encounter shapefiles that encode projected information. In such cases the contents of the shapefiles will be coded in coordinates using values that represent meters or feet in some projected coordinate system.

To use such files we must know the projection and projection parameters used to encode the shapefile. Because the shapefiles themselves do not contain this information we must receive it through other means such as a "readme.txt" file that accompanies the shapefiles or other documentation.

This example shows how to import a projected shapefile where we know what projection was used to encode the shapefiles. This example assumes a text file accompanies the shapefile to tell us what projection it is in.

**Step 1: Determine correct projection**

Our first task is to find out what projection the shapefile is in.

In Windows Explorer we can see that the "shapefile" is actually three files: a mexico.shp file, a mexico.dbf file and a mexico.shx file. In addition, we see that there is a readme.txt file that accompanies the shapefiles. If we are lucky, this text file contains information about the shapefiles such as the projection this shapefile is to use.

We can either pop open the text file in Notepad, or, using File - Import - Comments import it into Manifold as a comments component as seen above.

If we open the comments component we see the readme.txt file tells us that the projected shapefile was projected using Orthographic projection centered at latitude 24 degrees longitude -102 using WGS84.

These are "magic numbers" in that if the author of the drawing did not provide them to us we would have no way of knowing from the shapefile itself which projection and parameters to use.
Experienced user may object that this example begins right away with a page out of fantasy-land, in that it is rare that someone who is so thoughtless as to publish projected information in shapefiles will have the courtesy and foresight to provide a "readme" file that tells us what projection to use. But that happens surprisingly often, or, if the information is not in an accompanying text file it will be available in some "metadata" file or in some web page associated with the site from which we downloaded the shapefile.

People who use legacy formats normally get street-smart very quickly about the need to do a little detective work to find out what projections are intended if projected data is in play. For the sake of this topic we assume that such detective work has found the necessary information in the form of an accompanying text file.

**Step 2: Import shapefile using defaults**

We will import a projected shapefile that shows Mexico. This example is not accompanied by a sample file on the Manifold CD.

![Import Dialog](image)

In Manifold, choose **File - Import - Drawing**. In the **Import** dialog browse over to the directory in which the shapefile is located. Choose **SHP Files (*.shp)** in the **Files of type** box and open the **mexico.shp** file.
Manifold will automatically open the .shp file as well as the other two files normally used in SHP format. In the Import SHP File dialog we see this drawing has but one field, a column called Place_name. We press OK to import the drawing.

The result is a new drawing in the project pane. We can open the drawing by double-clicking on it in the project pane.
When opened the drawing appears OK. If one does not have a practiced cartographic eye one might not notice that the shape of Mexico is characteristic of projected maps as opposed to the "wide" appearance of countries in these latitudes as seen in unprojected Latitude / Longitude views. If we move the cursor over the drawing the coordinates seen in the status bar will show there is something not yet right about the coordinates in this drawing.

We can see that even though the drawing has been imported using **Latitude / Longitude** degree coordinates the coordinates shown in the status bar as the mouse moves over the drawing are values like 99517 and 56020, which are impossible values for degrees. Since shapefiles do not provide projection information but are mostly used for unprojected drawings, Manifold uses a default of **Latitude / Longitude** to import shapefiles. For correct use within Manifold, the correct projection **must** be specified for this drawing.

### Step 3: Specify correct projection

To specify the correct projection we launch the Edit - Assign Projection dialog and change parameters as necessary.

![Assign Projection dialog](image)

This is a familiar dialog used within Manifold for several similar purposes. In this case the purpose is to specify what projection parameters should be used to interpret the coordinate values in the drawing. The dialog shows the current interpretation applied, that the drawing is in **Latitude / Longitude** projection using degrees as the unit of measure for coordinates.
We expand the Azimuthal heading and choose the Orthographic projection.
We specify 24 as the Center Latitude and -102 as the Center Longitude. The datum is already WGS84 so there is no need to change the datum. Press OK.
There is no change in the appearance of the drawing. However, if we move the mouse over the drawing we can see there is a change in the status bar readouts.

| Orthographic | 101°36.336' W 24°9.028' N |

The status bar now reports the drawing is in Orthographic projection. The position of the cursor is reported in values that make sense for longitudes and latitudes in Mexico.

**Regional Settings**

When importing data from text file formats like .csv or from .dbf or shapefiles the Regional Options in the system have to match settings within the file that is being imported. This is because such simple formats are too stupid to understand that in different countries people use different symbols to denote decimal points (that is, either a dot character or a comma). To change Regional Options, do the following:

- Go to the Control Panel and open the Regional Options applet.
- Go to the Numbers page,
- Ensure that the Decimal Symbol is set to ‘.’ (dot),
- Ensure that the List Separator Symbol is set to ‘,’ (comma),
- Press Apply to apply changes if there were any,
- Import the .csv file or shapefile desired.
- After import, restore the original settings of Decimal Symbol and List Separator Symbol if you like.

Another option is to invoke the Data Sources applet (hidden within Administrative Tools folder of the Control Panel if you’re running Win2K) and create a file DSN for the .csv file you want to import. After creating the DSN configure it to use the comma character as a data separator.

**Notes**

A recent addition to shapefiles is the use of a .prj file that saves projection information. However, this is a recent addition that is not found with most projected shapefiles that are available. A further problem is that .prj files do not provide unambiguous projection information and so place users at risk of importing shapefiles that use .prj and still getting inaccurate projection information. If we are using projected shapefiles that are accompanied with .prj files, we should still make every effort to find out what projections are intended and then confirm the result of the import as in the example above.

A sample file for this example is not provided on the Manifold CD because of the risk of confusing users with a projected shapefile should someone try to open the file without reading this example first.
Import a Raw Binary File - NLCD

This topic uses the Import Surface - Raw Binary importer to import a raster data set that represents land used data in the state of Delaware in the US.

Derived from the early to mid-1990s Landsat Thematic Mapper satellite data, the National Land Cover Data (NLCD) is a 21-class land cover classification scheme applied consistently over the United States. The spatial resolution of the data is 30 meters and mapped in the Albers Conic Equal Area projection, NAD 83. The NLCD are provided on a state-by-state basis. The state data sets were cut out from larger "regional" data sets that are mosaics of Landsat TM scenes. At this time, all of the NLCD state files are available for free download as 8-bit binary files and some states are also available on CD-ROM as a Geo-TIFF.

Although there are now other land cover data sets that may be freely downloaded, this particular data set can be used to show import of binary files.

Step 1: Acquire the Data

Visit the NLCD download page currently at

and drill down into the final publication download site at

http://edcftp.cr.usgs.gov/pub/data/landcover/states/

Download the files for Delaware. Note that as always, URLs in this Help file may be changed after Help has been published. The USGS land cover web pages seem full of dead links and ongoing changes, so finding the data for this example may be difficult. The Delaware NLCD folder in the help examples folder on the Manifold CD contains a copy of these files.

There are three files to download: the data file in .gz compressed form and two text files:

- delaware_nlcd.bin.gz
- delaware_FGDC.txt
- delaware_readme.txt

Decompress the .gz file using WinZip or some other decompression package into a .bin file:

- delaware_NLCD_flat_042400.bin

Step 2: Open the FGDC File

We will copy information from the FGDC file into settings in the Manifold importer. To make this easier, we open the delaware_FGDC.txt file in Notepad or some other text editor. This file provides lots of metadata information for this data set.

Step 3: Launch Manifold and Import File

Without closing Notepad, we launch Manifold, open a project and choose File - Import - Surface. In the Import dialog we choose the Raw Binary Files importer in the Files of Type box and browse over to where we have saved the delaware_NLCD_flat_042400.bin file. We open it.
The Import Raw Binary File dialog opens. We will adjust some of the values in this dialog using values cited in the FGDC text file we have open in Notepad. Using the Windows task bar we will switch to Notepad, copy a value, switch to Manifold and paste the value into the Import Raw Binary File dialog.

Copy the value next to Row_Count and paste it into the Import Raw Binary File dialog's Height box.

Copy the value next to Column_Count and paste it into the Import Raw Binary File dialog's Width box.
Verify the number of Channels is set to 1 and Type is set to Integer (8-bit) and then press OK.

The result is a new surface in the project pane.

**Step 4: Open Surface and Specify Projection Information**

Open the surface by double-clicking on it. It is shown by default as an exquisitely detailed gray scale image. For best appearance, use View - Display Options to turn off Shading and Autocontrast.
Since the surface was not in a georeferenced format it has been imported into the default Orthographic projection. The first time the surface is opened, Manifold will raise an info bar as seen above to warn us that the projection has not yet been verified. In this case, we will use the same dialog used to verify the projection to manually add projection information.

To do so, we click on the info bar to launch the Edit - Assign Projection dialog. We can get the required projection information from the FGDC text file we have open in Notepad and enter it into the dialog.

Launch the **Assign Projection** dialog by clicking on the information bar shown in the surface window.
From the metadata we know to use the Albers Conical Equal Area projection, the ellipsoid (not shown in the screen shot but visible in Notepad), the Center Latitude, Center Longitude and other parameters for the projection dialog.
We can copy the projection parameters value from Notepad and paste into the Coordinates dialog as shown above. The Abscissa Resolution value goes into the Local scale X box and the Ordinate Resolution value goes into the Local scale Y box.

Press OK and the surface will be correctly imported and georegistered. Henceforth the surface and any images created from it will be georeferenced.

NCLD Classification Codes

The classification codes are imported into a surface as "heights" when we create a surface from raw binary data.

Import a VMAP Level 1 File

VMAP Level 1 is the most detailed public domain digital map of international regions currently available. See the Import Drawing - VMAP topic for a discussion of VMAP. VMAP levels 0 and 1 are products of the former National Imagery and Mapping Agency (NIMA) of the United States, renamed in a fit of bureaucratic irrelevance to the National Geospatial-Intelligence Agency, NGA. NIMA used to provide VMAP for free download. NGA may or may not make VMAP available for download.

Step 1: Download the Data

Visit the NGA site at http://www.nima.mil and drill down to their geodata downloads page (currently at http://geoengine.nima.mil). NIMA may choose to change their site at any time so this topic does not provide a detailed description of how to locate and download data from NIMA's site. If for any reason NGA no longer provides VMAP, users should file a Freedom of Information Act request to obtain this data.

Step 2: Unzip / Extract the Files

A .gz file is a "gnu-zipped" file that uses open source software to perform compression similar to Windows .zip files. .tar files are UNIX files that are created by the TAR ("tape archiver") program, which performs a function in UNIX similar to that of the arj program in DOS and UNIX. TAR can take many files organized in directories and combine them into a single file. It's a handy way of bundling related files together for transmission. .tar files must extracted into the many smaller files that comprise them.

When we download v1155.tar.gz from NIMA's site, what we've downloaded is a .tar file (a collection containing numerous files inside the .tar file) that has been further compressed into a .gz file. We can decompress the .gz and also extract the .tar file it contains using WinZip.

To do this, place the v1155.tar.gz file into a folder and double click it [assuming, of course, you've already installed WinZip on your system]. Note: before using WinZip to decompress files of this type, launch WinZip and make sure that WinZip's Option - Configuration - Miscellaneous tab does not have a check for "TAR file smart CR/LF conversion."

WinZip will open the .gz and see the compressed .tar file it contains. It asks us if we want to decompress it and open the .tar file. Click Yes. The following decompression process may take a while on a slow machine. WinZip will then display all of the files in the .tar file. Extract them all to a convenient directory, preferably named for the originating file. For example, we would extract all of the files from v1155.tar.gz into a directory called v1155.

Step 3: Import into Manifold
Launch Manifold. Before importing, create a folder in the project pane named v1155. Importing VMAP results in a huge number of files, so it is best to keep them organized within their own folder in the project pane.

To import, choose **File - Import - Drawing** and choose **VMAP Files (dht)** in the Files of Type box. Browse over to the folder where you placed the files extracted from v1155.tar.gz, browse down into the directory tree into the soamafr folder and double-click on the dht file that is located there.

The dht file is a catalog of what is available within the numerous files in various subdirectories below it. The **Import VMap Data Set** dialog allows us to choose which data we wish to import. For this example, we will choose Hydrography and Transportation and press OK.

A seemingly endless list of components is created in the project pane within two folders named Hydro and Trans. Two maps named Hydro and Trans are created as well. The two maps group the various hydro and trans drawings within a map for convenience. We can open these maps or open individual drawing or labels components.
The 1155 file covers a very large area because it includes a data set that is normally provided on the VMAP1 155 CD. The illustration above shows the hydro map zoomed in to central Panama with all layers but the Hydrotxt_lib_155_hydro layer turned on.

Applying some formatting can help comprehension. The scene above shows Costa Rica near the border with Panama. The lines in the WatcrsI_lib_155_hydro layer have been formatted in blue color.
VMAP1 imports into Manifold as georegistered drawing so it is easy to combine them with other georegistered components in maps. For example, we can download and import the DTED Level 0 data for this region and drag and drop the resultant surfaces into the map to create the scene above. We’ve also formatted the labels for greater visibility.
Query Templates

This topic provides templates that show the structure of generic queries that may be applied in individual situations.

Replace the meta names in angle < > brackets with the appropriate items to create real queries from these templates. Field names created by the query are given in **boldface** within square [] brackets. Otherwise, square brackets indicate optional items.

Note that SQL is case insensitive. The style below uses the traditional CAPITALS for SQL words, but this is not necessary. SQL is also insensitive to white space such as tabs, space characters and new lines so that one may adopt whatever writing style format is judged most legible and understandable. The style below uses traditional formatting.

Simple Query

```
SELECT <fields> FROM <tables> WHERE <condition> GROUP BY  <fields> HAVING <criteria> ORDER BY <expression>;
```

Show New Columns Created with Computations

```
SELECT <field1>+<field2> AS **Sum**, <field1>*<field2> AS **Product** FROM <table>;
```

Using Aggregate Functions

```
SELECT Max(<field>), Min(<field>), Avg(<field>) FROM <table>;
```

Total Records

```
SELECT Count(*) FROM <table>;
```

Total Records with Condition

```
SELECT Count(*) FROM <table> WHERE <condition>;
```

Linked Tables

```
SELECT DISTINCT <table1>.* FROM <table1> INNER JOIN <table2> ON <table1>.<field1> = <table2>.<field2>;
```

Linked Tables with Condition

```
SELECT DISTINCT <table1>.* FROM <table1> INNER JOIN <table2> ON <table1>.<field1> = <table2>.<field2> WHERE <condition>;
```

Grouping by Field

```
SELECT <field1>, Count(<field2>) FROM <table> GROUP BY <field1>;
```

Grouping with Filter

```
SELECT <field> FROM <table> GROUP BY <field> HAVING Count(*) > 1;
```
Text Pattern Matching

SELECT * FROM <table> WHERE <field> LIKE "A%";

Text Pattern Matching using Regular Expression

SELECT * FROM <table> WHERE <field> LIKEEX "[A-F].+";

Filtering by Certain Values

SELECT * FROM <table> WHERE <field>
IN (<value1>, <value2>, <value3>);

Filtering by Subquery

SELECT * FROM <table1> WHERE <field1> > ANY
(SELECT <field2> FROM <table2> WHERE <condition>);

Ordering by Field

SELECT * FROM <table> ORDER BY <field> ASC;

Top Records

SELECT TOP <number_of_records> FROM <table>
ORDER BY <field> DESC;

First and Last Value

SELECT First(<field>) AS [First], Last(<field>) AS [Last]
FROM <table>;

Parameterized Query

PARAMETERS <parameter> <type>;
SELECT <fields> FROM <tables> WHERE <condition-with-parameter>;

Update Query

UPDATE <table> SET <field>=<expression> WHERE <condition>;

Drop Table

DROP TABLE <table>;

Create Table

CREATE TABLE <name> (<field1> <type>, <field2> <type>);

Add Table Field

ALTER TABLE <name> ADD <field> <type>;
Add Table Field with Default Value

ALTER TABLE <name> ADD <field> <type> DEFAULT <default>;

Change Table Field Type

ALTER TABLE <name> ALTER <field> <type>;

Rename Table Field

ALTER TABLE <name> RENAME <field> TO <newName>;

Drop Table Field

ALTER TABLE <name> DROP <field>;

Delete Records from Table

DELETE FROM <table> WHERE <condition>;

Insert Records into Table

INSERT INTO <table> VALUES (<value1>, <value2>);

Select Records into New Table

SELECT <fields> INTO <newTable> FROM <table> WHERE <condition>;
Sample Queries

The *Nwind* sample database provided on CD with Manifold System is a version of the standard Microsoft *Northwind.mdb* database that is provided with Microsoft Access. It contains numerous tables and queries that may be used to learn database and query concepts.

This topic lists queries that are part of the *Nwind* database, with some minor adjustments for Manifold SQL.

**AutoLookup**

```
SELECT DISTINCTROW Orders.[Order ID], Orders.[Order Date], Orders.[Customer ID], Customers.[Company Name], Customers.Address, Customers.City, Customers.Region, Customers.[Postal Code], Customers.Country, Customers.Phone FROM Customers INNER JOIN Orders ON Customers.[Customer ID] = Orders.[Customer ID] ORDER BY Orders.[Order ID];
```

**Catalog**

```
SELECT DISTINCTROW [Categories].[Category Name], [Products].[Product Name], [Categories].[Description], [Products].[Product ID], [Products].[Quantity Per Unit], [Products].[Unit Price], [Products].[Discontinued] FROM [Categories] INNER JOIN [Products] ON [Categories].[Category ID] = [Products].[Category ID] WHERE ([Products].[Discontinued] = No) ORDER BY [Categories].[Category Name], [Products].[Product Name];
```

**Category List**

```
SELECT DISTINCTROW Categories.[Category Name], Categories.[Category ID] FROM Categories ORDER BY Categories.[Category Name];
```

**Category Sales for 1993**

```
SELECT DISTINCTROW [Sales for 1993].[Category Name], Sum([Sales for 1993].[Product Sales]) AS [Category Sales] FROM [Sales for 1993] GROUP BY [Sales for 1993].[Category Name];
```

**Customer List**

```
SELECT DISTINCTROW Customers.[Company Name], Customers.[Customer ID] FROM Customers ORDER BY Customers.[Company Name];
```

**Daily Order Totals**

```
SELECT DISTINCTROW Orders.[Order Date], Count(Orders.[Order ID]) AS [CountOFOrder ID], Sum([Order Subtotals].Subtotal) AS SumOfSubtotal FROM Orders INNER JOIN [Order Subtotals] ON Orders.[Order ID] = [Order Subtotals].[Order ID] GROUP BY Orders.[Order Date];
```

**Employee List**

```
SELECT DISTINCTROW Customers.[Company Name], Customers.[Customer ID], Customers.Region, Customers.[Postal Code], Customers.Country, Customers.Phone FROM Customers ORDER BY Customers.[Company Name];
```
Examples

SELECT DISTINCTROW [Last Name] & ", " & [First Name] AS [Employee Name], Employees.[Employee ID]
FROM Employees
ORDER BY [Last Name] & ", " & [First Name];

Employee Sales by Country (Parameter)

PARAMETERS [Beginning Date] DateTime, [Ending Date] DateTime;
SELECT Orders.[Order ID], [Last Name] & ", " & [First Name] AS Salesperson, Employees.Country, Orders.[Shipped Date], [Order Subtotals].Subtotal AS [Sale Amount]
FROM Employees INNER JOIN (Orders INNER JOIN [Order Subtotals] ON Orders.[Order ID] = [Order Subtotals].[Order ID]) ON Employees.[Employee ID] = Orders.[Employee ID]
WHERE ((Orders.[Shipped Date] Between [Beginning Date] And [Ending Date]))
ORDER BY [Last Name] & ", " & [First Name], Employees.Country, Orders.[Shipped Date];

Employee Sales for 1993

SELECT DISTINCTROW SUM([Order Subtotals].Subtotal) AS [Employee Sales], [First Name] & " " & [Last Name] AS [Employee Name], Employees.[Last Name], Employees.[First Name]
FROM Employees INNER JOIN ([Order Subtotals] INNER JOIN Orders ON [Order Subtotals].[Order ID] = Orders.[Order ID]) ON Employees.[Employee ID] = Orders.[Employee ID]
WHERE ((Orders.[Order Date] Between #01/1/93# And #12/31/93#))
GROUP BY [First Name] & " " & [Last Name], Employees.[Last Name], Employees.[First Name];

Freight Charges

SELECT DISTINCTROW Shippers.[Company Name], Orders.[Order ID], Orders.Freight, Orders.[Shipped Date]
FROM Shippers INNER JOIN Orders ON Shippers.[Shipper ID] = Orders.[Ship Via]
WHERE ((Orders.[Shipped Date] Between #03/25/93# And #03/31/93#))
ORDER BY Shippers.[Company Name], Orders.[Order ID];

Invoices

SELECT DISTINCTROW Orders.[Shipped Date], Orders.[Ship Name], Orders.[Ship Address], Orders.[Ship City], Orders.[Ship Region], Orders.[Ship Postal Code], Orders.[Ship Country], Orders.[Customer ID], Customers.[Company Name], Customers.[Address], Customers.City, Customers.Region, Customers.[Postal Code], Customers.Country, Employees.[Last Name], Employees.[First Name], [Order Details].[Order ID], Orders.[Order Date], Orders.[Required Date], Orders.[Ship Via], [Order Details].[Product ID], Products.[Product Name], [Order Details].Quantity, [Order Details].[Unit Price], [Order Details].Discount, Orders.Freight
FROM Employees INNER JOIN ((Customers INNER JOIN Orders ON Customers.[Customer ID] = Orders.[Customer ID]) INNER JOIN (Products INNER JOIN [Order Details] ON Products.[Product ID] = [Order Details].[Product ID]) ON Orders.[Order ID] = [Order Details].[Order ID]) ON Employees.[Employee ID] = Orders.[Employee ID]
ORDER BY Orders.[Shipped Date];

Order Details Extended

SELECT DISTINCTROW [Order Details].[Order ID], Products.[Product Name], [Order Details].[Product ID], [Order Details].[Unit Price], [Order Details].Discount, [Order Details].Quantity, [Order Details].[Required Date], [Order Details].[Shipped Date], [Order Details].[Ship Via], [Order Details].[Order ID], Orders.[Order Date], Orders.[Required Date], Orders.[Ship Via], [Order Details].Quantity, [Order Details].[Unit Price], [Order Details].Discount, Orders.Freight
Details.Quantity, [Order Details].Discount, CLng([Order Details].[Unit Price]*[Quantity]*(1-[Discount])*100)/100 AS [Extended Price]
FROM Products INNER JOIN [Order Details] ON Products.[Product ID] = [Order Details].[Product ID];

Order Information

SELECT DISTINCTROW Orders.[Order ID], Orders.[Customer ID], Customers.[Company Name], Customers.Address, Customers.City, Customers.Region, Customers.[Postal Code], Customers.Country, Orders.[Ship Name], Orders.[Ship Address], Orders.[Ship City], Orders.[Ship Region], Orders.[Ship Postal Code], Orders.[Ship Country], Orders.[Ship Via], Orders.[Employee ID], Orders.[Order Date], Orders.[Required Date], Orders.[Ship Date], Orders.Freight
FROM Customers INNER JOIN Orders ON Customers.[Customer ID] = Orders.[Customer ID]
ORDER BY Orders.[Order ID];

Order Review

SELECT DISTINCTROW Orders.[Order ID], Orders.[Order Date], Orders.[Required Date], Orders.[Shipped Date], Orders.[Customer ID], Customers.[Company Name], Employees.[Last Name], Shippers.[Company Name] AS [Ship Via], [Order Subtotals].Subtotal, Orders.Freight, [Subtotal]+[Freight] AS Total
FROM Employees INNER JOIN (Shippers INNER JOIN (Customers INNER JOIN ([Order Subtotals] INNER JOIN Orders ON [Order Subtotals].[Order ID] = Orders.[Order ID]) ON Customers.[Customer ID] = Orders.[Customer ID]) ON Shippers.[Shipper ID] = Orders.[Ship Via]) ON Employees.[Employee ID] = Orders.[Employee ID]
ORDER BY Orders.[Order ID] DESC;

Order Subtotals

SELECT DISTINCTROW [Order Details].[Order ID], Sum(CLng([Unit Price]*[Quantity]*(1-[Discount])*100)/100) AS Subtotal
FROM [Order Details]
GROUP BY [Order Details].[Order ID];

Product List

SELECT DISTINCTROW Categories.[Category Name], Products.[Product Name], Products.[Product ID], Products.[Units In Stock], Products.[Reorder Level], Products.[Units On Order], Products.[Quantity Per Unit], Products.[Unit Price], Categories.Description, Products.Discontinued
FROM Categories INNER JOIN Products ON Categories.[Category ID] = Products.[Category ID]
WHERE ((Products.Discontinued=False))
ORDER BY Categories.[Category Name], Products.[Product Name];

Product Names and IDs

SELECT DISTINCTROW Products.[Product Name], Products.[Product ID]
FROM Products
ORDER BY Products.[Product Name];

Products and Suppliers

SELECT DISTINCTROW Products.[Product Name], Products.[Product ID], Products.[English Name], Products.[Category ID], Products.[Supplier ID], Products.[Quantity Per Unit], Products.[Unit Price], Products.[Units In Stock], Products.[Units On Order], Products.[Reorder Level],
Examples

Products.Discontinued, Suppliers.[Company Name], Suppliers.[Contact Name], Suppliers.City, Suppliers.Country, Suppliers.Phone
FROM Suppliers INNER JOIN Products ON Suppliers.[Supplier ID] = Products.[Supplier ID]
ORDER BY Products.[Product Name];

Products on Order

SELECT DISTINCTROW Categories.[Category Name], Products.[Product Name], Products.[Units In Stock], Products.[Units On Order], Suppliers.[Company Name], Suppliers.Phone
FROM Categories INNER JOIN (Suppliers INNER JOIN Products ON Suppliers.[Supplier ID] = Products.[Supplier ID]) ON Categories.[Category ID] = Products.[Category ID];

Quarterly Orders by Product (Crosstab)

TRANSFORM Sum(CLng([Order Details].[Unit Price]*[Quantity]*
  (1-[Discount])*100)/100)
SELECT Products.[Product Name], Orders.[Customer ID]
FROM Orders INNER JOIN
  (Products INNER JOIN [Order Details] ON Products.[Product ID] = [Order Details].[Product ID]) ON Orders.[Order ID] = [Order Details].[Order ID]
WHERE ((Orders.[Order Date] Between #01/1/93# And #12/31/93#))
GROUP BY Products.[Product Name], Orders.[Customer ID], Orders.[Order Date]
ORDER BY Products.[Product Name]
PIVOT "Qtr " & DatePart("q",[Order Date]) In
  ("Qtr 1","Qtr 2","Qtr 3","Qtr 4");

Quarterly Orders by Product (Make Table)

SELECT DISTINCTROW [Quarterly Orders by Product (Crosstab)].[Product Name], [Quarterly Orders by Product (Crosstab)].[Customer ID], [Quarterly Orders by Product (Crosstab)].[Qtr 1], [Quarterly Orders by Product (Crosstab)].[Qtr 2], [Quarterly Orders by Product (Crosstab)].[Qtr 3], [Quarterly Orders by Product (Crosstab)].[Qtr 4] INTO [Quarterly Orders]
FROM [Quarterly Orders by Product (Crosstab)];

Sales by Category

SELECT DISTINCTROW Categories.[Category Name], Products.[Product Name],
  Sum(CLng([Order Details].[Unit Price]*[Quantity]*(1-[Discount])*100)/100) AS [Product Sales]
FROM Orders INNER JOIN ((Categories INNER JOIN Products ON Categories.[Category ID] = Products.[Category ID]) INNER JOIN [Order Details] ON Products.[Product ID] = [Order Details].[Product ID]) ON Orders.[Order ID] = [Order Details].[Order ID]
WHERE ((Orders.[Order Date] Between #01/1/93# And #12/31/93#))
GROUP BY Categories.[Category Name], Products.[Product Name]
ORDER BY Categories.[Category Name], Products.[Product Name];

Sales by Date (Parameter)

PARAMETERS [Beginning Date] DateTime, [Ending Date] DateTime;
SELECT DISTINCTROW Orders.[Order ID], Orders.[Shipped Date],
  Customers.[Company Name], [Order Subtotals].Subtotal AS [Sale Amount]
FROM Customers INNER JOIN ([Order Subtotals] INNER JOIN Orders ON [Order Subtotals].[Order ID] = Orders.[Order ID]) ON Customers.[Customer ID] = Orders.[Customer ID]
WHERE ((Orders.[Shipped Date] Between [Beginning Date] And [Ending Date]))
ORDER BY Orders.[Order ID];

Sales by Product

SELECT DISTINCTROW Products.[Product ID], Orders.[Order Date],
    Sum(CLng([Order Details].[Unit Price]*[Quantity]*(1-[Discount])*100)/100) AS [Product Amount]
FROM Orders INNER JOIN (Products INNER JOIN [Order Details] ON Products.[Product ID] = [Order Details].[Product ID]) ON Orders.[Order ID] = [Order Details].[Order ID]
GROUP BY Products.[Product ID], Orders.[Order Date];

Sales by Sale Amount

SELECT DISTINCTROW [Order Subtotals].Subtotal AS [Sale Amount], Orders.[Order ID], Customers.[Company Name], Orders.[Shipped Date]
FROM Customers INNER JOIN (Orders INNER JOIN [Order Subtotals] ON Orders.[Order ID] = [Order Subtotals].[Order ID]) ON Customers.[Customer ID] = Orders.[Customer ID]
WHERE ((Orders.[Shipped Date] Between #10/1/93# And #12/31/93#))
ORDER BY [Order Subtotals].Subtotal;

Sales for 1993

SELECT DISTINCTROW Categories.[Category Name], Products.[Product Name],
    Sum(CLng([Order Details].[Unit Price]*[Quantity]*(1-[Discount])*100)/100) AS [Product Sales]
FROM Orders INNER JOIN ((Categories INNER JOIN Products ON Categories.[Category ID] = Products.[Category ID]) INNER JOIN [Order Details] ON Products.[Product ID] = [Order Details].[Product ID]) ON Orders.[Order ID] = [Order Details].[Order ID]
WHERE ((Orders.[Order Date] Between #01/1/93# And #12/31/93#))
GROUP BY Categories.[Category Name], Products.[Product Name];

Sales Totals

SELECT DISTINCTROW [Employees].[First Name] & " " & [Last Name] AS Name,
    Orders.[Employee ID], Count(Orders.[Order ID]) AS [CountOfOrder ID],
    Sum([Order Subtotals].Subtotal) AS SumOfSubtotal
FROM Employees INNER JOIN ([Order Subtotals] INNER JOIN Orders ON [Order Subtotals].[Order ID] = Orders.[Order ID]) ON Employees.[Employee ID] = Orders.[Employee ID]
GROUP BY [Employees].[First Name] & " " & [Last Name], Orders.[Employee ID];

Subquery

SELECT DISTINCTROW Customers.[Contact Name], Customers.[Company Name],
    Customers.[Contact Title], Customers.Phone
FROM Customers
WHERE ((Customers.[Customer ID] In (SELECT DISTINCTROW Orders.[Customer ID] FROM Orders
WHERE Orders.[Order Date] BETWEEN #04/1/93# AND #07/1/93#))));

Summary of Sales

4040
Examples

```
SELECT DISTINCTROW Orders.[Shipped Date], Orders.[Order ID], [Order Subtotals].Subtotal AS [Order Amount]
FROM Orders INNER JOIN [Order Subtotals] ON Orders.[Order ID] = [Order Subtotals].[Order ID];
```

Summary of Sales (Parameter)

```
PARAMETERS [Beginning Date] DATETIME, [Ending Date] DATETIME;
SELECT DISTINCTROW [Orders].[Shipped Date], [Orders].[Order ID], [Order Subtotals].[Subtotal], Year([Shipped Date]) AS [Year]
FROM [Orders] INNER JOIN [Order Subtotals] ON [Orders].[Order ID] = [Order Subtotals].[Order ID]
WHERE ([Orders].[Shipped Date] BETWEEN [Beginning Date] AND [Ending Date]);
```

Supplier List

```
SELECT DISTINCTROW Suppliers.[Company Name], Suppliers.[Supplier ID] FROM Suppliers
ORDER BY Suppliers.[Company Name];
```

Ten Most Expensive Products

```
SELECT DISTINCTROW TOP 10 Products.[Product Name] AS [Ten Most Expensive Products], Products.[Unit Price]
FROM Products
ORDER BY Products.[Unit Price] DESC;
```

Union Query

```
SELECT [Company Name], [City]
FROM [Suppliers]
WHERE Country = "Brazil"
UNION SELECT [Company Name], [City]
FROM [Customers]
WHERE Country = "Brazil";
```
Using SQL to Select Map Objects

This topic provides a collection of queries that select map objects. When such queries are based on spatial relationships such as proximity they are often called spatial queries.

The normal use of queries is to generate a table display showing the results of the query. If the query includes the ID field in its results, query tables can automatically select the drawing objects corresponding to each row in the query table based upon the setting of the Automatically select query records option in the Tools - Options - Miscellaneous dialog. When this option is checked (the default setting) queries will automatically select objects in the drawing.

That is, with this option on querying a drawing will automatically deselect any selected objects and then select all objects returned by the query. This is equivalent to making a selection using Replace mode. When a query includes more than one drawing, all previously selected objects in all of the drawings will first be deselected and then objects from the query will be selected in the first drawing for which an ID column is found in the query.

If the Automatically select query records option is not checked then running a query will generate a tabular display of the query results, but the objects in that query will not automatically be selected. We can then use such a query-generated table to manually select objects in the drawing with interactive mouse commands much as we could use a drawing's table to select objects in the drawing.

The first three examples show the basic mechanism of selecting objects in drawings using the content of fields in their associated tables.

SELECT States.* FROM States WHERE IsArea(States.ID) AND (SELECT Max(Area(Counties.ID)) FROM Counties WHERE Contains(States.ID, Counties.ID)) > 100;

Selects states that have at least one large (>100 area units) county from the drawing called states.

SELECT DISTINCT FastFood.* FROM FastFood, Streets WHERE FastFood.Type = "McDonalds" AND Streets.Name = "Rue Delaunay" AND Distance(FastFood.ID, Streets.ID) < 100;

Selects all McDonalds restaurants near the street named Rue Delaunay in the drawing streets. Note the 'DISTINCT' just before the 'FastFood.*' This suppresses duplicate fastfood entries, a necessary step when querying restaurants in Paris given the famous French interest in McDonalds and other haute cuisine.

When queries are based on spatial relationships such as proximity they are often called spatial queries. The following examples show queries that select objects in maps based on spatial relationships.

SELECT Stations.Name, Distance(Stations.ID, 12, "mi") FROM Stations;

This creates a tabular view where the first column shows the name of the station and the second column shows the distance in miles from this station to the station whose ID is 12.

SELECT Stations.* FROM Stations WHERE Distance(Stations.ID, 12, "km") Between 50 And 80;

This selects all stations whose distance to station 12 is between 50 and 80 kilometers.

SELECT Stations.* FROM Stations WHERE (SELECT Min(Distance(Stations.ID, Clients.ID, "mi")) FROM Clients WHERE Clients.Importance = "High") < 10;

SELECT Stations.* FROM Stations WHERE
Examples

(SELECT Max(Distance(Stations.ID, Clients.ID, "mi")) FROM Clients
    WHERE Clients.Importance = "High") < 10;

The first query selects all stations within 10 miles of any important client. The second query selects all stations
within 10 miles of important clients.

SELECT TOP 5 PowerPlants.* FROM PowerPlants, States WHERE
    (States.Name = "California" Or States.Name = "Nevada") AND
    Contains(States.ID, PowerPlants.ID) ORDER BY PowerPlants.Power;

This selects the 5 largest power plants in California and Nevada.

SELECT States.Name FROM States WHERE EXISTS
    (SELECT * FROM Rivers WHERE Rivers.Name = "Mississippi" AND
    Touches(States.ID, Rivers.ID));

This selects all states on the banks of the Mississippi.

We may also use SQL as a utility language to perform functions that might otherwise require a script. For
example, suppose we would like to determine the nearest (non-self) neighbor of points in a drawing. We can loop
through all points in the drawing and use the following to select the ID of the nearest neighbor of the point whose
ID equals X:

SELECT TOP 1 [ID] FROM [Drawing] WHERE [ID] <> X
ORDER BY Distance([ID], X);

Alternatively, we can execute the following query to list the nearest neighbor of each object:

SELECT [ID], (SELECT TOP 1 [Copy].[ID] AS [Nearest Neighbor] FROM
    [Drawing] AS [Copy] WHERE [Copy].[ID] <> [Drawing].[ID] ORDER BY
    Distance([Copy].[ID], [Drawing].[ID])) FROM [Drawing];

Rank Columns / Decision Support System

Rank Columns are used to construct a Decision Support System query and to report the results. A rank column reports percentages. The Manifold Decision Support System (DSS) provides a way to select records using flexible criteria with queries. DSS results are reported as percentage values from 0 to 100 percent within a rank column in a table. Creating a rank column creates a DSS query, the results of which are reported in the column.

In this example we will open the Order Details table and find all "luxury" goods. We shall define luxury goods to mean those goods that are both "expensive" and "rare". Expensive goods, in turn, are defined to be those goods for which the unit price is "high" and rare goods are those goods for which quantity is "low."

Step 1: Import and open the table

Import the Order Details table from the Nwind.mdb sample database.

<table>
<thead>
<tr>
<th>Order Details *</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unit Price</td>
</tr>
<tr>
<td>22</td>
</tr>
<tr>
<td>21.35</td>
</tr>
<tr>
<td>27</td>
</tr>
<tr>
<td>43.7</td>
</tr>
<tr>
<td>66</td>
</tr>
<tr>
<td>30.7</td>
</tr>
<tr>
<td>34</td>
</tr>
<tr>
<td>4.2</td>
</tr>
<tr>
<td>11.3</td>
</tr>
<tr>
<td>16.2</td>
</tr>
<tr>
<td>7</td>
</tr>
</tbody>
</table>

In this example we show only the Unit Price and Quantity fields for brevity.

Step 2: Add a rank column

Choose Table - Add - Rank Column to add a rank column.
This command launches the **Add Rank Column** dialog, which is used to add criteria and to create the query that will generate this rank column. Begin by changing the name to **Luxury**. This will be the name of the rank column as it will appear in the table.

**Step 3: Add criteria**

We will add two criteria.

1. Click on the **New** button to add the first criterion.

In the **Add Criterion** dialog, enter **Expensive** as the name of this criterion. Choose **Unit Price** for the column and **High** for the Type of criterion. The pane on the right shows the criterion curve that is automatically generated by DSS based on the data in the table. In essence, we've defined a criterion to find expensive goods by finding unit prices that are high. Press **OK**. (See the Add Rank Column Dialog topic for detailed instructions on the **Add Criterion** dialog.)
Back in the **Add Rank Column** dialog, the result is a new criterion that is saved in the hierarchical diagram under the name of the column (field) it uses, **Unit Price**. If we were to expand the **Unit Price** level we would see a criterion called **Expensive** underneath it.

Click on the **New** button once more to add another criterion.

For this criterion we will use the name **Rare**. We choose **Quantity** for the field (column) to use and **Low** for the type. The pane on the right shows the criterion curve generated by DSS for records that have low quantity values. This is a way of finding "rare" goods in that their quantities are low. Press **OK**.

Back in the **Add Rank Column** dialog we now have two fields in use with for criteria, the **Quantity** and the **Unit Price** fields.

**Step 5: Drag and drop criteria to create a rank query**

We create rank queries by dragging and dropping criteria from the upper pane in the **Add Rank Column** dialog to the lower pane. We begin by expanding the levels in the upper pane so we can see the criteria from which we can choose.
We drag and drop the Rare criterion from the upper pane to the lower pane.

The Rare criterion appears in the rank query pane under Criteria. So far, we've built a query that selects all records that are "rare", that is, for which quantity is "low". To make this a more interesting query we will drag and drop the Expensive criterion from the upper pane into the lower rank query pane.
The **Expensive** criterion now joins the **Rare** criterion in the rank query pane. By default, new criteria are added using Boolean **OR** to create a combined query. So far, our query will find all goods that are either rare or are expensive. We would like to amend this query so it finds those goods that are both rare and expensive.

To do so, we double click into the **Junction** field and change it to **And**.
The new rank query is now equivalent to "Select all records that are Rare and Expensive." So far, so good; however, we would like to find only those goods that are very expensive. We can "nudge" a criterion to accentuate it or de-emphasize it by using the **Hedge** column.

Double clicking into the **Hedge** column for the Expensive criterion we can choose **very** as the hedge.
The result is a query that finds all records that are Rare and very Expensive. [Note: The Not field allows us to prefix each criterion with a Not Boolean modifier. So, we could find records that are Rare and Not very Expensive if desired.]

Press OK to add the rank column using this query to the Order Details table.

**Step 6: Admire result**

A new column called **Luxury** appears in the Order Details table. It is a rank column and formatted by default to show percentages with two digits of accuracy after the decimal point. A gray background indicates it is a special column.

<table>
<thead>
<tr>
<th>Unit Price</th>
<th>Quantity</th>
<th>Luxury</th>
</tr>
</thead>
<tbody>
<tr>
<td>36.6</td>
<td>4</td>
<td>100.00 %</td>
</tr>
<tr>
<td>97</td>
<td>3</td>
<td>100.00 %</td>
</tr>
<tr>
<td>55</td>
<td>4</td>
<td>100.00 %</td>
</tr>
<tr>
<td>203.5</td>
<td>4</td>
<td>100.00 %</td>
</tr>
<tr>
<td>123.79</td>
<td>2</td>
<td>100.00 %</td>
</tr>
<tr>
<td>55</td>
<td>4</td>
<td>100.00 %</td>
</tr>
<tr>
<td>263.5</td>
<td>2</td>
<td>100.00 %</td>
</tr>
<tr>
<td>99</td>
<td>4</td>
<td>100.00 %</td>
</tr>
<tr>
<td>55</td>
<td>1</td>
<td>100.00 %</td>
</tr>
<tr>
<td>52.5</td>
<td>4</td>
<td>100.00 %</td>
</tr>
<tr>
<td>52.5</td>
<td>4</td>
<td>100.00 %</td>
</tr>
<tr>
<td>81</td>
<td>1</td>
<td>100.00 %</td>
</tr>
<tr>
<td>55</td>
<td>2</td>
<td>100.00 %</td>
</tr>
<tr>
<td>53</td>
<td>3</td>
<td>99.90 %</td>
</tr>
<tr>
<td>53</td>
<td>2</td>
<td>99.90 %</td>
</tr>
<tr>
<td>53</td>
<td>3</td>
<td>99.90 %</td>
</tr>
</tbody>
</table>

We can click on the column head to sort the tables by the values in the Luxury column. If we do so, we can see that those records given a 100% ranking all have very high prices and low quantities. Further down in the table are those records with not quite so very expensive prices or perhaps slightly greater quantities. At the very end of the table are those products that are cheap and abundant.
Shortest Path over Land

Finding the shortest path between two points is a typical task. Usually we find such a shortest path through a network made up of road lines. At times we may want to find the shortest path between two locations that satisfies other criteria in a region where there is no road network. For example, we might want to find the shortest path between two points that does not cross any water bodies, or we may want to find the shortest path between two points that never rises above a given terrain elevation, avoids certain obstacles or otherwise is constrained.

This example considers the general problem of finding the shortest distance between two points when travel is allowed only within a specified region. In the example we will find the shortest distance between two points where travel must occur on land within Mexico.

The general solution to this and other similar problems is to first build a network that exists only within the allowed region. We can then use the network to find a shortest path. Most of the procedure’s steps are creating the network. Once we have the network the rest is easy. To build a network we will create a regular grid of points. We will then remove all points that do not lie on land. We then build the network using the remaining points.

This is an unusually long example that will seem very intricate to a newcomer. For experienced hands it is very rapidly done. Beginners should have faith that mastery of elementary maneuvers in Manifold will allow them to speed through tasks like this example.

Step 1: Import drawing and prepare drawing

We begin by importing the mexico_eg.mif sample drawing. Open the drawing and choose Edit - Change Projection to open the projection dialog.

![Projection Dialog]

Project the drawing into Orthographic projection using the default parameters offered by pressing the Suggest button. Press OK.
The drawing will now appear in Orthographic projection. It is important to project the drawing so default measurements appear in meters.

Later in this example we will use spatial overlays to transfer field values for objects over land. To facilitate use of spatial overlays, we will add a field to the drawing's table. To add a field, open the drawing's table, right click onto any column head and choose Add - Column from the context menu.

In the Add Column dialog, choose the name Land for the new field and press OK to create the new field using the default type of Integer (32-bit). [We could, of course, create this as a Boolean field if desired since we will use this field to flag land areas. We used the integer type out of sheer laziness because it is the default.]

A new column called Land appears in the table. We now will set the value of Land to 1 for all land areas.

To do this, we press CTRL-A to select all the records in the table. We could have also chosen Edit - Select All from the menu.
We double click into any of the **Land** cells and enter the value 1 and press **Enter**.

This enters the value 1 into the **Land** column for all selected records. Next, we need to set the Transfer Rule for this column. To do so, we right click onto the **Land** column head and choose **Transfer Rules** from the context menu.

In the **Column Transfer Rules** dialog we choose **Copy** for the **1 to N** rule. The transfer rule tells Manifold how to allocate the value in this column when it is transferred to other objects. The **1 to N** rule is used when one of the objects (such as an area) transfers its value to many other objects (such as points within that area). The **Copy** rule tells Manifold to take the value in the object and to copy it into all of the receiving objects.

**Step 2: Create a grid of points**

Click back onto the drawing to move the focus there. We will now create a grid of points in the drawing. Begin by pressing View - Grid.

The **Grid** dialog opens with values estimated from the size of the open drawing window. We will change the **spacing** parameter to 100000 meters. This will create a grid of lines separated by horizontal and vertical intervals of 100 km. That's a fairly coarse grid but suitable for our example. Create the grid by pressing the **Create** button. This creates a grid of line objects in the drawing.

The choice of a grid interval is an important matter for the approximations that follow. The finer the grid, the finer will be the network we build from it. The finer the network, the greater the accuracy of the shortest path approximation. However, the finer the grid the greater the network analytic task as well as all geometric tasks involved in the construction of the network. We **strongly** urge the new user to begin with very coarse grids to master the technique. One can later progress to denser grids in gradual steps to see where performance...
becomes unacceptably slow. Experts who are sure of their technique may use dense grids that could take a weekend of processing to perform some tasks for a final result.

The Grid dialog is a dual-purpose dialog. It can be used to show a grid of lines created by the system that "floats" above the drawing but is not a part of it. In addition, it can be used to create line objects in the drawing in the shape of the grid. We've used the Grid dialog to create a grid of line objects. However, we do not want to show a grid overlay in addition to that. So, we uncheck the Show grid box and press OK to exit the Grid dialog.

In the drawing we now have a grid of lines spaced at 100 km vertical and horizontal intervals. We will create points at their intersections.

To do so, we first select all of the lines. Do this by pressing in the Select Lines select objects button and pressing out the Select Areas and Select Points buttons. We can then press CTRL-T or choose Edit - Select By Type from the menu to select all of the lines. [This is such a common task that it is good to become accustomed to pressing CTRL-T for faster editing.]

In the Transform toolbar, choose the [Selection] as the scope and Points as the transform operator. This will create points at the ends of all lines in the selection.
Examples

The result is the creation of many points that are separated from each other by the same vertical and horizontal interval, 100 km, used to create the lines.

While the points are selected, we can use the Remove Duplicates transform operator to eliminate any duplicated points. There will be duplicated points since four lines come together at each intersection and thus creating a point at the end of each line results in coincident points at the intersections.

We don't need the lines anymore so we can delete them. The easiest way to do this is to press CTRL-T to select by type again (the selection modes should still be set to select lines only) and then press Delete to blow away the lines.

The result is a grid of points that are separated by 100 kilometers.

**Step 3: Eliminate points over water using Spatial Overlays**

Our next task is to eliminate all points that are not located over land areas. We begin the task by selecting all points and saving them (using the Selections pane) to a saved selection called **Points**. To do so, open the Selections pane.
Select all of the points by pushing in **Select Points** select objects button only and pressing **CTRL-T** to select by type. Save the selection into the Selections pane and name it **Points**.

We also need to save the areas. To do so, push in the **Select Areas** select objects button only and press **CTRL-T** to select by type. Save the selection into the Selections pane and name it **Areas**.

The above two steps are not illustrated. Note the use of **CTRL-T** for speed. We could have also used the **Edit - Select By Type** menu choice if preferred.

In the Selections pane we now have two saved selections. One saved selection is called **Areas** and the other is called **Points**. We will use these saved selections with the Spatial Overlay dialog.

Launch the **Spatial Overlays** dialog by choosing **Drawing - Spatial Overlays**. In the dialog choose the saved selection called **Areas** as the **Source** and the saved selection called **Points** as the **Target**. Choose **Areas to contained points** as the **Method**. This tells Manifold to transfer the field values in accordance with the Transfer Rules from those objects in the source set to those objects in the target. We will transfer the field values from the areas to all points within the areas. Press **OK**.

In complex maps or those with many intricate areas, spatial overlays can take a long time to run. The geometric computation to determine if a point is inside or outside a given area can be very complex. Remember that areas in Manifold can be topologically branched objects where a single area object can have holes and islands. The computation to deal with arbitrarily complex topology can be very time consuming. This particular example will take approximately five to fifteen minutes to compute on desktop machines in the 500Mhz to 1 gigahertz range. Increasing the number of points or the number or complexity of the areas will increase the time required.

The spatial overlays operation will copy the field values from the areas to the points they contain. Every point located over a land area will receive the value 1 in its **Land** column. All points over water will stay with the default value of 0 in their **Land** column which was placed there when they were created from the grid of lines using the **Points** transform.

To create a grid of points that exists over land areas, all we need do now is select all points with a value of 0 and delete them. There are many ways of doing this, but we will use a somewhat indirect method to illustrate a few more techniques in Manifold.

Open the drawing’s table and click on the **Land** column to sort the table by that column. Scroll down to the first record with a value of 1 in its **Land** column. Ctrl-click on that record to select it. Scroll down to the bottom of the table to the last record with a value of 1 in the **Land** column and Shift-CTRL-click on that record to select all the records between the two clicks, thus selecting all objects with a value of 1 in the **Land** column.
In the drawing window, we can see that this has selected all of the land areas as well as the points over land. To eliminate the points over water, we can choose **Edit - Select Inverse** (which selects only the points over water) and press **Delete**.

From here on in it is more convenient to work in a map window. We create a map from the *Mexico_eg Drawing* and add a drawing layer to the map that we call **Nodes**. We will also add a drawing layer we call **Links**. We will move the points from the Mexico drawing to the **Nodes** drawing layer. First, we select all of the points (using **CTRL-T** or **Edit - Select By Type**) and then we cut the points using **CTRL-X** or **Edit - Cut**, click on the **Nodes** layer tab and then paste the points using **CTRL-V** or **Edit - Paste**.

When pasting the points into the new layer, Manifold will raise a dialog asking us how to paste the fields for the points. We don't really need any of the fields any more so it doesn't matter whether we paste the fields or not. The result will be a new drawing layer filled with points that are all above land areas in Mexico, as seen in the illustration above.

**Step 4: Build a network**

Our task now is to use the grid of points to build a network. We will use the Distance Network transform to wire up links between nearby points. To use this transform sensibly we have to figure out what the right distance is to specify that will create links between neighboring points.
The Tracker tool can help us. We will use the tool to measure distances.

Using the tracker tool, we can measure the distance from one point to its diagonal neighbor. It turns out this distance is approximately 141 kilometers (as the more mathematically inclined reader already knew, since the grid of points is 100 kilometers apart). The illustration above shows the use of the tracker together with the Snap to achieve precise measurement of distance between points.

That distance measurement means that if we want the **Distance Network** to build links to the immediate horizontal, vertical and diagonal neighboring points we should use a distance of 150,000 meters. Click on the **Links** layer in the map so that the new lines will be created there. We then load the transform toolbar as seen above and press **Apply**.
The result is that the lines created by the **Distance Network** appear in the **Links** layer in our map. [For the illustration above we have also formatted the **Nodes** layer so that points in the layer are bright green dots.]

![Map with links and nodes](image)

Some housekeeping: The **Distance Network** solver will create duplicates of some links. We eradicate these by running the Remove Duplicates transform in the **Links** layer.

One other item of housekeeping: At least one link has been created over water, across the Sea of Cortez between the Baja peninsula and mainland Mexico.

We can zoom into the map, select the unwanted link and press the **Delete** key to delete it.
For a small map and a small network as used in this example it is easiest to delete any links created over water by hand. For more complex networks, we can use spatial overlays once more to transfer the value 1 to all links that are contained by the land areas. We can then remove all links with a value of 0.

**Step 5: Find the shortest path**

All of the above steps, for all of their apparent intricacy served only to create the network we will now use to find shortest paths. The geometry of the network captures the essential information, where are paths that go over land and where are water regions to be avoided. All the rest is just a trivial matter of finding the shortest path through a network.

To find the shortest path between two points we click on the **Nodes** layer and select two points. In the example above, we've selected one point at the tip of the Baja peninsula and another point at near the eastern end of Mexico.
We then click on Links and select all of the lines in that layer (we do this by pressing **CTRL-A** or choosing **Edit - Select All** since there are only lines in this layer).

We then load the transform toolbar with the settings seen above. This instructs Manifold to use the current selection (two points and a network of lines) with the Select Shortest Path transform operator to select the links that comprise the shortest path between the two points.

Press **Apply** and the shortest path will be selected.

To see the shortest path better, we can press **CTRL-C** or **Edit - Copy** to copy the links involved and then paste them into a new drawing layer called **Path**. We can then format the lines in **Path** in a larger size so they stand out better.
Discussion

Clearly, the above method results in an approximation to the "perfect" shortest path. As the grid of points and resultant network get denser the approximation comes closer and closer to the shortest path that would be obtained if the path were not constrained to travel over a network.

Note also that the above procedure can be generalized to build networks within given regions. For example, suppose we had a surface that showed the terrain elevations in Mexico. Perhaps we are interested not just in overland paths, but only in those overland paths that stay below an elevation of 1000 meters. We could use the surface to build contour areas. We could then use spatial overlays to mark all points in the grid that fall within contour areas that are lower than 1000 meters in elevation and eliminate higher points. If we build a distance network using the remaining points we will have a network that exists only in those overland locations that are below 1000 meters elevation.

Suppose we were interested in travel between random points and not just those points on our grid? Perhaps, for example, we study Mayan civilization and we want to know the shortest paths between various Mayan cities. These are easy to add: after creating a regular grid of points we simply copy the points showing the locations of the cities and add them to the layer in which the grid of points is located. We then create a distance network using the combined grid of points and the irregularly arranged city points. To find shortest paths we can then use our layer of city points to select start and end points. Since copies of these points were part of the set of points used to create the distance network we know that each of the city points is correctly located at the end of links in the network.

This procedure describes a highly interactive approach to creating and using networks for special purposes. We might want to add some analytic dimension, such as a Viewbot that reports the sum of the lengths of lines in the selection. If we select the shortest path using the Select Shortest Path transform we can then see immediately the length of the shortest path.

If we like, we might copy the shortest path and place it in its own layer where we can run the Join Lines transform to create one line from the path.

We could then create a label using the Length (l) intrinsic field to label the shortest path with the length, as seen above. If we had many shortest paths in our map, such as the various shortest paths between cities, we could label all of the shortest paths with their lengths.

We used the above example to mark points that occurred over a relatively simple landform. The same procedure would have worked fine had the landforms included lakes or other more complex water features.
Extract Last Names using Tokens

This example uses Transform toolbar token operators to create a new column in a table that extracts the last name from another column that contains a full name. We will work with a table associated with a drawing that shows US congressional districts.

</tbody>
</table>

The table’s Name field lists members of the 109th Congress in the US. We plan on using this drawing and table with the Manifold map server in a web page. To make it easy for browsers to find a member of Congress with a simple Find command, we would like to have a column that lists the last name only for each member. We feel it will be easier for browsers to find by entering "Peterson" than to have to try to remember the first name as well.

Our task is therefore to extract just the last name from the Name field and to put it into its own column, called Last Name. We can use tokens and the transform toolbar to accomplish this step.

Step 1: Get ready

We open the table in a table window. Next, we make ready with a few housekeeping items:

- **Separate tokens with:** 

We open the Tool Properties pane using SHIFT-ALT-T (or by clicking View - Panes - Tool Properties in the main menu). The default setting of the Separate tokens with box lists the space character (the blank location to the left of the  ), a tab, a carriage return and a newline character as the default token separator characters. Thus, every group of characters separated by these whitespace characters will be treated as a token. If the Separate tokens with box does not include a space character, add it.
It will be more convenient to work with the table if we hide all fields that are not necessary. We click on View - Columns and in the Columns dialog uncheck all the boxes except Name. This will hide all columns except Name.

That's better. We will now add two text fields to the table. Right click onto the Name column and choose Add - Column from the context menu.

In the Add Column dialog we create a new column called temp that is an ANSI variable length text column. Press OK. We will use this column as a temporary working space.
We also need to create the **Last Name** column that will hold our results. Right click onto the **Name** column again and choose **Add - Column** once more to create another column.

In the **Add Column** dialog we create one more column called **Last Name** that is also an ANSI variable length text column. Press **OK**.

We now have two new columns in our table.

**Step 2: Remove last token**

We observe that the names can be thought of consisting as a sequence of tokens. For example, "**Collin C. Peterson (D)**" consists of four tokens: "**Collin**, "**C.**, "**Peterson**, and "**(D)**". We would like to move the next-to-last token into the **Last Name** column. Unfortunately, within Manifold there is no "Copy next-to-last token" command. There is, however, a **Copy Last Token from** operator. If we get rid of the "(**D)**" and "(**R)**" last tokens we can then use the **Copy Last Token from** operator to extract the last names.

We begin by copying all of the values from the **Name** column into the **temp** column.

To do so, load up the transform toolbar as seen above and press **Apply**.
Like magic, Manifold copies all of the Name values into the temp column.

To delete the "(D)" and "(R)" tokens at the end of the values in the temp column we use the Delete last token operator in the transform toolbar as seen above. Press Apply.
We now have a column of names in temp where the final token is the last name we seek.

**Step 3: Copy last token into last name field**

To copy the last token we use the **Copy Last Token from** operator in the transform toolbar to copy the last token from the temp field into the Last Name field. Press **Apply**.

It seems we are done… but are we?

**Step 4: Correct mistake**

Unfortunately, we did not notice that the table contains names of the form "Henry E. Brown, Jr. (R)". For such records, copying the last token in the step above results in a Last Name field that contains the value "Jr.". No need to panic: we will find all such records and repair them.

To find all such records, we click on the Last Name column header to sort the column and then we scroll down to the section where all of the "Jr." records are located. We want our repair action to operate only selected records, so we will select all of the fields with "Jr." in the Last Name field. A fast way to do this is to click on the record handle of the first such record to select it.
We can then \textit{SHIFT-click} on the record handle of the last "Jr." record.

That will select all records from the previously selected record to the record where the \textit{SHIFT-click} occurred. We now have selected all the records with "Jr." in the \textit{Last Name} field. We could have used the Query toolbar to make this selection, but since we have all the records together in view in the table it was easier just to click and then shift-click.
The transform toolbar for tables uses **autoscope**: if any records are selected, it will automatically restrict the action of any transform operator to only the selected records. So long as only these records are selected, any operations we do in the transform toolbar will apply only to them.

We will begin by getting rid of the "Jr." tokens at the ends of the **temp** column values using the **Delete Last Token** operator as seen above. Press **Apply**.

This gets rid of the final "Jr." tokens at the ends of the fields in the selected records. Note that no changes were made to unselected records. However, we have a slight problem: there is a comma at the end of the selected names in the **temp** column. If we simply copy the last token into the **Last Name** field we will end up with some last names that have an unwanted comma at the end. We must first get rid of the commas.

To do this, we load up the toolbar with the **Delete Right** operator with a parameter of 1. This operator removes the last \(n\) characters on the right where \(n\) is the value given in the parameter box. Press **Apply**.
Nothing happens! The commas are still there.... what's going on? What's happened is that after we deleted the terminal "Jr." tokens a space character was left behind in the values in the temp field. When we used Delete Right with a parameter of 1 it deleted the space characters at the end of the strings. We need to apply Delete Right one more time.

As before, we load up the toolbar with the Delete Right operator with a parameter of 1. Press Apply.
Much better… we have now removed the final commas and are ready to copy the last names.

The final operation is to use **Copy Last Token from** to copy the last tokens from the **temp** field to the **Last Name** fields for the selected records.
The table is now almost in final form. All that remains is to right click onto the temp column head and choose Delete to delete the temporary field. We also deselect all records.

Our table now contains a Last Name field that has been extracted from the Name field.

Notes

This example used the default list of separators, where a space character denotes white space. A more sophisticated use of tokens might add other, non-whitespace characters to the token separator characters in the Tool Properties pane.

For example, suppose we have an address field containing text values such as “123 Main Street, Sioux Falls, South Dakota”. We could remove the space character from the token separator list and add the comma character “,” as a token separator. We could then copy the different parts of the address to different fields. In this case “123 Main Street” would be the first token, “Sioux Falls” would be the second and “South Dakota” would be the third token.
Import Landsat Files and Create Composite RGB Image

Before reading this example, review the Combining Channels into Images topic.

Landsat 7 images are often delivered as several .dat files that are accompanied by one or more header files. Each frequency band acquired by the satellite has one .dat file. For example, band 3 is Red, band 2 is Green and band 1 is Blue. The header files give information on the organization of the files.

In this example we import Landsat 7 Fast-L7A format .dat files to create a composite RGB image. We then alter the image to provide better contrast. Finally, we combine the RGB image with a higher resolution panchromatic image to provide an image that has both high resolution and color tinting. The result is an enhanced image that has much better readability than default R, G, B composites created using Landsat bands.

**Step 1: Determine image sizes**

By reviewing the header files (we can open them with Notepad or import them as comments components into Manifold) we can see the organization of the .dat files.

**PIXELS PER LINE = 1720 LINES PER BAND = 3322**

The header.hpr file in the line above tells us that most bands have 1720 width (pixels per line) and 3322 height (lines per band). The .hpr file defines parameters for bands 1, 2, 3, 4, 5, and 7.

Similarly, the header.hpn file tells us that the panchromatic band has 3440 height and 6644 width. This makes sense, since we know from the PIXEL SIZE parameter listed in the header files that most Landsat 7 bands provide 25 meter resolution while the panchromatic band provides 12.5 meter resolution. For the same area the panchromatic band therefore should have twice as many pixels as the other bands. The header.htm file provides information for the relatively low resolution bands 6h and 6l, which have pixels that are 50 meters in size. These bands are not used in this example.

**Note:** The example uses a recent Landsat 7 data set using the Fast-L7A data format. Older Landsat data has lower resolution, with 30 meter resolution in most bands and 15 meter resolution in the panchromatic band. Read the header files to see the exact specifications for your data set. The header.htm file provides information for the relatively low resolution bands 6h and 6l, which have pixels that are 50 meters in size.

**Step 2: Import .dat files**

Use File - Import - Surface with Files of Type set to Raw Binary Files (*.bin, *.dat, *) to import band1.dat.

In the Import Raw Binary File dialog we use the settings shown above with a Width of 1720 and a Height of 3322. Press OK. The result of the import is a new surface. Import band2.dat and band3.dat using the same settings.
When we finish the imports we will see three surfaces in our project file. The **Header** comment component was created when we imported the **header.hpr** file (not shown explicitly in this example) as a comment. We did this to find out the values of **Width** and **Height** to use for importing.

**Step 3: Create mask images**

We will now create grayscale mask images from the surfaces. These can then be combined in the R, G and B channels of an RGB image to create a composite color image.

Open the **Band1** surface. It appears as a speckled pattern. Choose **View - Display Options** to open the **Display Options** dialog.

In the **Display Options** dialog, uncheck the **Shading** and **Autocontrast** boxes. Press **OK**.

The result is a visible "image" seen in the surface window. It is a grayscale representation of the contents of **Band1**, the blue band from Landsat's Enhanced Thematic Mapper remote sensing instrument.

To save **Band1** as an image, we click on **Edit - Save Mask / Channel**.

![Image of the Display Options dialog with Shading and Autocontrast unselected](image-url)
In the **Save Mask / Channel** dialog we choose Channel: grayscale in the Save To box. In the To box we provide the name of the image to be created. We will enter Band 1 (Blue) so that later we will not be confused what the origin is of this image or what the intended usage of it is. Press OK and a new image called Band 1 (Blue) will be created. This new image is exactly the same size as the surface from which it was created: 1720 by 3322 pixels.

We can repeat the above process for the Band2 and Band3 surfaces. We open each surface in turn and use **Save Mask / Channel** to create an image from it.

The result of our work so far is that we now have three surfaces and three images created from them. We don't need the surfaces any more so if we are working on a machine with limited RAM we can delete them if desired.

**Step 4: Create an RGB image and load R, G and B channels**

We will now create an RGB image and then populate the R, G and B channels of the image from the mask images we created in the previous step.

We begin by creating a new RGB image. Double-click open one of the mask images, such as Band 1 (Blue).

Next, choose File - Create - Image and enter the above values into the **Create Image** dialog. Note that the size of the image is specified as exactly the same size as the surfaces originally imported and the mask images created from them: 1720 by 3322 pixels.

**A digression:** We clicked open the Band 1 (Blue) image because any newly-created image will use whatever coordinate system is in use by an open image window that has the focus when the new image is created. This is a nuance that has no effect in this example as written because all images so far are in the default Orthographic projection; however, if we had georegistered the band surfaces when they were first imported (to, say, UTM projection normally used with Landsat images) we would want all subsequent components to be created using the same projection.
We open the new image and see it is entirely black (as a newly created image will be by default). We can now populate it with R, G and B channel information from the saved mask images.

Choose Edit - Load Mask/Channel and in the Load Mask/Channel dialog specify the red channel in the Load box and the Band 3 (Red) image in the From box. We use the default mode, Replace, so the contents of the mask override whatever is in the image's red channel. Press OK.
The red channel will now be populated in our image. Since only red values appear, the image will seem to be a reddish rendition of the Band 3 (Red) grayscale image.

We choose Edit - Load Mask/Channel once again and in the Load Mask/Channel dialog we specify the green channel in the Load box and the Band 2 (Green) image in the From box. Press OK.
The green channel will now be populated as well as the red channel. Since greens and reds together make yellows, the image appears mostly in yellow tones.

Yet again we choose **Edit - Load Mask/Channel** and in the **Load Mask/Channel** dialog we specify the **blue** channel in the **Load** box and the **Band 1 (Blue)** image in the **From** box. Press **OK**.
With all three channels populated the image appears in "natural" shades. Like many Landsat images it seems to have poor contrast as if seen through a hazy atmosphere. Image processing within Manifold and use of other bands can improve the contrast.

**Step 5: Process image for better appearance**

If desired, we can open each of the band images, such as **Band 1 (Blue)**, and adjust their brightness and contrast. We can then load the R, B and G channels again using the adjusted band masks.

Opening the **Band 1 (Blue)** image we see it does not have a very great contrast variation.
Using the Brightness / Contrast command we can increase the contrast and decrease the brightness slightly. We will also open the Band 2 (Green) image and increase the contrast on that image as well.

We can also import band7.dat which provides an image using infrared frequencies. We will import band7.dat and create a mask image from it as we did for the other three bands in step 3 above. We can then open the resultant mask image and increase the contrast on that image.

Next, we repeat step 4 above to re-load the R, G and B channels of the composite RGB image. We use the increased contrast blue and green mask images and the new, increased contrast infrared image for the red channel. This achieves a composite image with enhanced appearance.
If desired, we can adjust the Brightness / Contrast on this image and also increase the saturation using Hue / Saturation to achieve even greater definition.

**Step 6: Incorporate panchromatic band for increased resolution**

We can increase the resolution of the image yet further by combining information from the panchromatic Landsat band. The Landsat bands used so far have a resolution of 25 meters per pixel.

<table>
<thead>
<tr>
<th>Local offset</th>
<th>X</th>
<th>Y</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0.00</td>
<td>0.00</td>
</tr>
<tr>
<td>Local scale</td>
<td>25.00</td>
<td>25.00</td>
</tr>
</tbody>
</table>

We can specify this for the composite image by opening the Edit - Assign Projection dialog and specifying 25 meters as the X and Y Local scale.

However, the panchromatic instrument in Landsat creates a grayscale image using green to infrared wavelengths that has 12.5 meter resolution. We can import this surface from band8.dat using a setting of 3440 for width and 6644 for height. Like the other images, we can create an image from the surface using Edit - Save Mask/Channel. We can then open the mask image and increase the contrast slightly.
The result is seen above, zoomed into the same area shown in the other illustrations. Clearly, the panchromatic instrument provides better resolution. We can exploit this enhanced resolution by using the panchromatic image together in a map with the composite RGB image.

To do so, we first have to tell Manifold the pixel size of the panchromatic image. We do this by opening Edit - Assign Projection and specifying 12.5 meters as the X and Y Local scale.

Next, we create a map component using the panchromatic image, we open the map and then we drag and drop the composite RGB image into the map. Drag the composite image layer to below the panchromatic layer. Change the opacity of the panchromatic image to 70% so the colors from the composite image underneath can show through. Finally, open the composite image in its own window and increase the saturation using Hue / Saturation to a very high value so that the colors seen in the map window will be reasonably clear even though they are seen through the panchromatic grayscale image.
The result (seen above) provides visual cues from the high resolution grayscale panchromatic image that are tinted by the colors from the composite RGB image seen from below. Our eye is assisted by the black and white detail from the high-resolution image into seeing a clearer picture of the landforms.

However, the image could have better contrast. There are several ways to accomplish increased contrast. One way is to alter the contrast of the panchromatic image and to adjust the opacity to allow more or less of the RGB image to show through. A different way is to merge the panchromatic image and the RGB image into a single image and to then make contrast adjustments to that combined image.

To merge our map view of the partially transparent panchromatic image and the RGB image into a single image, with the map view open we create a layout for the map, and then the Tools - Make Image command to create a single image from the map at whatever resolution is desired. Note that Make Image preserves the coordinate system (projection) of whatever component it images.

We can then open the resulting image and apply commands such as Autocontrast in the transform toolbar to create the result seen above. Clearly, it's a long way from the original assembly of R, G and B channels as seen below.
**Step 7: Georegistering the image**

When Landsat bands are imported as surfaces they are imported using the default Orthographic projection with a scale of one pixel per meter. All components created from these original surfaces will have the same projection. To superimpose different bands having different pixel sizes upon each other in a map we must at least inform Manifold of the scales for each image using the **Edit - Assign Projection** dialog as done above.

To use the images in any geographic context we must also tell Manifold what projection is to be used. If we know the projection (from, for example, a reading of the header files) we can specify the projection in **Edit - Assign Projection** as well. The image will then be georegistered.

If the Landsat image is to be correctly georegistered, this would actually be one of the first steps in the process, immediately upon importing the .dat files. However, since many users will employ a Landsat image purely for visual effect and don't care whether it is registered or not we have placed this step at the end of the sequence.

To georegister the Landsat image we need to know what projection was used for it. From the header.hrf file giving specifications for all bands except 8 and 6h and 6l we read:

GEOMETRIC DATA MAP PROJECTION =UTM
ELLIPSOID =GRS80
DATUM =GDA
USGS MAP ZONE = 55
LL = 1462457.5412E 432422.2444S 452712.500 5193912.500

The LL values provide the coordinate location of the lower left corner of the display with the first pair of numbers given in degrees - minutes - seconds and the second being the offset in meters within the UTM zone 55 projection coordinate system. This magic information may be found through careful reading of documentation for Landsat.

To georegister this image, all we need do is correct the projection information loaded by default (Orthographic) into what the projection of the image actually is. To do this, we use the **Edit - Assign Projection** dialog.

In this projection we enter

**Universal Transverse Mercator - Zone 55 (S)** as the projection. The datum is Geodetic Reference 1980. The Local offset values are 452712.50 and 5193912.50. The Local scale values are both 1.00. The Scale correction values are 0.9996 and the False easting/northing is 500000.00 for X and 10000000.00 for Y.

Where did these values come from? Some came from the selection of the projection zone and some we added as follows:

From the header.hrf file we know the projection is UTM zone 55. We know that this is the UTM zone from the Universal Transverse Mercator (South) collection of UTM projections because the LL value gives a South latitude in the degrees - minutes - seconds pair of numbers for LL. Expert readers will immediately realize the Landsat image in question is in the Southern Hemisphere (it shows a forest region in Tasmania).

The datum is set to Geodetic Reference 1980 using the ellipsoid and datum information in header.hrf as well. Sometimes when parsing government header files it is important to know what the various abbreviations (such as GRS80 and GDA) mean. Enough digging into documentation available on Internet will usually provide answers.

The Local offset values are taken directly from the second pair of LL values. The values for Local scale are taken from the PIXEL SIZE value given in header.hrf. This pixel size will be different for the other bands.

**Notes**

The above commentary on georegistering a Landsat image has been placed in Step 7 at the end of this topic in order not to confuse those readers who will be working with Landsat images for purely visual presentation where georegistration is not necessary.

When users desire a georegistered Landsat image, most will georegister the bands right after they import them in Step 2. All subsequent components created from the bands (such as images used as masks or composite
images) will then also be georegistered. To assure the composite RGB image is georegistered, make sure one of the mask images is opened and has the focus when the new RGB image is created. The new, blank image will then be created using the same coordinate system as the image that currently has the focus.
Cookie Cutter a Large Image with Transfer Selection

This example shows how to cut a region in the shape of a particular country out of a larger image. The image used is one of NASA's "Blue Marble" images of the Earth as seen from space in natural color. We will create a smaller image that shows only the region within Afghanistan. This same method can be used to cut out images that fit other countries, such as the United States, or regions such as Europe. Like any operations with larger images the operations in this topic should be performed on a reasonably fast computer that is equipped with plenty of RAM.

NASA's Blue Marble series of images provides spectacular views of the Earth as seen in natural color. Visit http://visibleearth.nasa.gov and search for "Blue Marble" to find them. Since web page URLs frequently, using a good search engine such as Google with search terms like "NASA", "Blue Marble", "land_ocean_ice_8192.tif" and similar may be required to find the images.

This image and others from the Blue Marble series is on the Manifold download site as well.

**Step 1: Import and georegister the image**

This example uses a medium resolution image downloaded in TIF format from the NASA site. It is 8192 pixels wide and 4096 pixels high and named `Land_ocean_ice_8192.tif`. Import the image using File - Import - Image. For brevity, henceforth we will refer to this image as "the image" instead of using the long name.

According to the NASA web site the image is in Latitude / Longitude projection, that is, no projection.

We import the image into Manifold. This particular image is very useful for maps showing land regions since it already uses transparent pixels for all ocean regions.

Because the image has been imported from ordinary .tif format (which does not save projection information) and not from GeoTIFF format (which uses the same .tif extension but does save projection information), there is no projection information available to Manifold and so it is imported using Orthographic projection. Manifold recognizes that as a sign the projection may need to be manually assigned and so when we first open the image Manifold will display an info bar advising us the projection in use has not yet been verified.

Our first tasks are to verify the projection and to georegister the image, which in this case consists of correctly assigning the projection to be used. We can accomplish both tasks by clicking on the info bar and then entering the correct projection parameters into the Assign Projection dialog that pops up.

If the image is 8192 pixels wide and the width of the image is 360 degrees (which it must be to cover the entire Earth in Latitude / Longitude projection) we know that the local scale in the X (width, East - West) direction is:
Examples

\[
360 / 8192 = 0.0439453125
\]

If the image is 4096 pixels high and the height of the image is 180 degrees we know likewise that the local scale in the Y (height, North - South) direction is:

\[
180 / 4096 = 0.0439453125
\]

To georegister the image, we click on the info bar and then use these values in the Edit - Assign Projection dialog.

An experienced user will know that images from geographically unaware formats will be imported with positive coordinates only. However, an image in Latitude / Longitude projection will span both negative numbers and positive numbers in the range -180 to +180 degrees longitude and -90 to +90 degrees latitude. The coordinate system for the image must therefore be offset by -180 in \( X \) and -90 in \( Y \) so that half of the image uses negative numbers in longitude and latitude as occur in Latitude / Longitude projection.

An inexperienced user will not normally remember (or know how) to specify the Local offset numbers. Instead, the user will discover the above numbers after showing an image in a map together with an accurately georegistered drawing or other component. If Local offset is left at 0 for \( X \) and \( Y \) the image will be placed so that...
the lower left corner of the image is at the intersection of the Equator and the Prime Meridian. By changing the X local offset to -180 and the Y local offset to -90 the image is moved correctly into place. Inexperienced users usually find the correct Local offset numbers in a trial and error process like that shown in the Manually Georegister an Image topic.

**Step 2: Show in a map with a drawing**

We will import the Countries drawing from the Manifold CD. This is a drawing in Latitude / Longitude projection in the Countries lowres.map file. We import it using File - Import - Component to import the drawing from the .map file.

Create a map using the Land_ocean_ice_8192 image and open the map so created.

Next, drag and drop the Countries drawing into the map.

The Countries drawing appears in the map using default formatting.
Because the map was created using the **Land_ocean_ice_8192** image it is in **Latitude / Longitude** projection and the **Countries** drawing is also in **Latitude / Longitude** projection. Just to be sure the drawing is in exactly the same projection used by the map and by the image, we will right click onto the **Countries** tab in the map and choose **Project to Map**. This guarantees the drawing is in the same projection as the map and will assure maximum speed.

The image will be hidden by the areas in the drawing. We are interested in seeing only the boundaries of the areas so that the regions underneath the areas in the drawing can be seen.

To make the image visible, click on the background color well for areas and change the background color to transparent color.

The result is an upper drawing layer that has transparent color for area backgrounds. The effect is as if we replaced the area objects in the drawing layer with boundary lines. The image is now visible and can be seen to be perfectly georegistered.

If we would like to have the area border lines stand out more, we can change the area border line foreground color from the default dark gray to black.

Now is a good time to save a copy of the .map project.

**Step 3: Select image pixels in Afghanistan**

We now will select pixels in the image that are within Afghanistan. To do this we will first select the area representing Afghanistan in the drawing and then transfer the selection to the image.
Zoom in to Afghanistan. Because we changed the area background color to transparent color we don't see the "inside" of the areas. All we see are the boundary lines for the areas, but each country shown in the country drawing is represented by an area. We can click within the boundary lines of any country to select the area representing that country.

Using **Select Touch**, click on the Afghanistan area to select it. The entire central part of the Afghanistan area is seen in red selection color. The entire area is shown in red selection color because the drawing contains areas and not just boundary lines. It only appears to consist of boundary lines because we have changed the background, color of the areas to transparent color.

We will now start editing the image based on the selection in the drawing. Click on the image's layer tab in the map to make it the active layer.
To transfer the selection to the image we launch the Image - Transfer Selection command. We choose to modify the image and check the box for the Countries drawing in the Using pane. Press OK. There is no immediate change in the appearance of the map because the red selection color that was shown in the drawing is now shown in the same location for the region of selected pixels in the image.

We double-click on the Countries layer tab in the map to turn it off and then click on the image layer tab to make the image layer the active layer again. Now that the drawing is no longer displayed in the map we can see that the selection is a region of pixels in the image.

**Step 4: Crop image to selected pixels only**

Our objective is to create an image of Afghanistan only. To do that we begin by cropping the image to Afghanistan only and then we will delete all pixels except the selected pixels.

We will begin by cropping the image to just that rectangular extent that contains the selected pixels. There is no point in working with an overly-large image if all we are interested in are the pixels that comprise Afghanistan.
In the Transform toolbar, use the Crop operator on the selected pixels and press Apply.

We can see we have cut out the rectangular region of pixels containing Afghanistan from the much larger original image. The image is now only 328 pixels by 208 pixels and so requires far less size to store. The smaller image will also allow faster system performance.

We now delete all pixels outside of Afghanistan. Choose Edit - Select Inverse to select all pixels outside of Afghanistan.
Choose Edit - Delete to delete these pixels. The background appears white because we are viewing a map that has a default background of white (see the Layers pane topic). If we switched off the background we could see that the image consists of the pixels within Afghanistan and invisible pixels.

In images, "deleting" a pixel turns it into an invisible pixel. Note from the Invisible Pixels topic that invisible pixels are still there even though they cannot be seen.

If we turn on the Countries layer once more we can see that the only visible pixels in the image are those in Afghanistan. In the illustration above we have renamed the image Afghanistan.

Now would be a good time to save this .map file so that in the future we could import the image whenever we need a georegistered image of Afghanistan. We could use that image by itself to create cool new maps or we could use it with other images and drawings for special effects.
For example, the above map was created by showing the cropped Afghanistan image in a map above the Countries drawing and a lower layer using the original image. The lower image layer is shown with 40% opacity to make it less vivid than the Afghanistan image. In addition, a drop shadow created using Gaussian Blur was added below the Afghanistan image.

**Step 5: Create a drop shadow (for advanced users)**

Drop shadows are frequently used to provide a "floating" effect as though some parts of a map are floating above other parts. The following description is not central to the main theme of this Example (the theme is using Transfer Selection to crop images to match desired areas in drawings) but for advanced users it shows how to create a drop shadow. As this section is intended for advanced users, the descriptions assume greater familiarity with Manifold System.

Copy the Afghanistan image and paste it as a new image. Rename the new image Shadow. Open the image in an image window.
Use Add Margin in the transform toolbar to add 50 pixels of margin. We will need the extra margin to make a drop shadow since the image was cropped right to the edge of Afghanistan.

Using Touch Select, click on the black margin to select it. Press Delete to "delete" it (that is, turn it into invisible pixels).
We now have the same image but with a larger margin of invisible pixels around Afghanistan. We will color the invisible pixels white and the Afghanistan pixels black.

Use Image - Adjust - Hue / Saturation and move the **Lightness** slider all the way to zero to make the Afghanistan pixels black. The invisible pixels are unaffected by the **Lightness** slider.
In the format toolbar make sure the foreground color is white and then use **SHIFT** - Paint Bucket to click anywhere in the region of invisible pixels to color them white. The **SHIFT** key will cause the white color to fill all invisible pixels anywhere in the image.

Use **Gaussian Blur** to blur the image by 10 pixels. So far, so good, except that we don't want a white background, we want a transparent background. This is accomplished using a mask to change the alpha channel transparency in the **Shadow** image.

Copy the **Shadow** image and paste it as a new image. Rename that image **Mask**.
Open the **Mask** image and use Image - Convert To to change the mask image into a **Grayscale** image. Only grayscale images can be used as masks. Close the **Mask** image and click on the **Shadow** image again to make it the active window.

Use the Edit - Load Mask/Channel command to load the **Mask** image into the alpha channel of the **Shadow** image.
The final result is a Shadow image that is a Gaussian drop shadow of the original Afghanistan pixel region. The amazing thing about Manifold as opposed to ordinary graphics editors is that this image is still georegistered to the original Afghanistan image. After all, it was pasted from the original, georegistered image and so was georegistered when it was pasted. Manifold maintained its georegistration throughout the entire sequence of image editing commands that were applied.

To use this drop shadow, we drag and drop it into our map underneath the Afghanistan image. The shadow appears immediately underneath the Afghanistan image, but to give a convincing optical effect to fool the eye we should offset the shadow slightly lower and to the right.

To do this we right click on the Shadow layer tab and choose Register. In the Register dialog we can change the Local offset in X and Y to displace the drop shadow downward and to the right so that it is partially visible underneath the Afghanistan layer. We increased the X value slightly and decreased the Y value slightly, the exact changes being found by trying different values with the Preview box checked.

As seen together with the Countries drawing layer and the Afghanistan image layer the Shadow layer gives a convincing impression of a drop shadow. Note that because the Shadow layer employs alpha channel transparency, it will correctly allow any other layer beneath it to show through in a convincing manner.

For example we can add a copy of the original image layer underneath all other layers and set the opacity of the background image layer to 40% to de-emphasize it. (We can get this copy of the original image layer by importing it from the .map project saved earlier in this example.) We can also add a labels component. Finally, we can move the Countries layer below the Afghanistan image so that the image would not be ringed with a black boundary line, and we can lower the opacity of the Countries layer so that the black border line is also de-emphasized.
The completed map is seen above.

Comments

Drop shadows created in the above manner are remarkable things in that they show correct transparency as regards any layers below them. If other drawing layers (such as railroads or hydrography) were turned on underneath the Afghanistan and Shadow layers, the drop shadow would correctly drape over any drawing objects passing underneath the shadow just as shadows do in real life.

How is it that we could use the Shadow image as a mask to specify transparency? This is a fortunate coincidence in that the transparency of an alpha channel is set by the range from black (no transparency) to white (full transparency) that exactly coincides with the grayscale range of the Shadow image. Using the Shadow image in grayscale form as its own alpha channel mask gives us the transparency we want in the drop shadow.

The detail-oriented reader will note that creating a margin of 50 extra pixels results in a slightly larger image than necessary for the Shadow image. After all, we need only those pixels that extend to the edge of the darker pixels created by the Gaussian Blur yet using the procedure above we are creating a Shadow image that is slightly larger than necessary because it involves invisible pixels beyond the reach of the shadow effect.

We could have arranged for a smaller image by using the Crop command on the Shadow image. After doing the blur, we could have selected a rectangular section of pixels in the Shadow image that extended just past the darker pixels created by the Gaussian Blur command and then cropped the Shadow image to that rectangular section. This is not such a big deal with such a small image, but it is a fine point of detail that might bear attention in the case of much larger images.
Download and Mosaic TerraServer Images

At the present writing, Microsoft's terraserver-usa.com web site provides free downloads of USGS images in one meter resolution for the United States. TerraServer may be accessed either via an interactive web site visited by users, or as a web service to which applications like Manifold may connect to automatically fetch desired images. See http://terraservice.net or http://www.terraserver-usa.com for details. As always, URLs are subject to change and often will change after documentation like this is written. If the URLs in this topic are no longer valid, use a good search engine to hunt down the new locations.

Important: The very cool Microsoft TerraServer should not be confused with the various non-Microsoft enterprises (such as terraserver.com) that have nothing to do Microsoft even though they have managed to obtain confusingly similar domain names.

TerraServer may be accessed either via an interactive web site visited by users, or as a web service to which applications like Manifold may connect to automatically fetch desired images.

- This topic shows how to work with images obtained using the interactive TerraServer website and how to manually assemble them into larger mosaics.
- The Linked Images from TerraServer topic describes how to use the built-in Manifold capability of automatically downloading and combining images from TerraServer.

For most purposes, using the built-in Manifold ability to fetch and assemble TerraServer images automatically is much more convenient than manually visiting the web site and then downloading and assembling images by hand.

 Nonetheless, we have provided this example using TerraServer because getting images from TerraServer is similar to how they may be Obtained From other sources. It also provides a set of images that are easily georegistered using the Assign Projection dialog so that the topic can teach the simple cut-and-paste methodology of making mosaics from georegistered images instead of getting bogged down into lots of discussion on how to georegister images.

The downloadable images provided by Terraserver are smaller than the original USGS DOQ images from which they are generated. To create an image that covers a larger area one must download several adjacent images from Terraserver and then mosaic the images together into a single, larger image.

This topic shows how to download two adjacent images and to mosaic them together. Although the specific steps illustrated are set forth for Terraserver, the general ideas and methods can be applied to piecing together images from other public access web sites from which images may be obtained.

As a general comment, there is not much to creating image mosaics in Manifold if the images involved are correctly georegistered. Simply copy and paste images together to make a larger image. Most time in such projects is usually spent finding the images, downloading them and georegistering them. The actual assembly of multiple images into a single larger image is trivial.

Step 1: Download the images

Microsoft's TerraServer site allows users to download the images displayed in .jpg format. It also allows download of a “world file” for each image. The world file provides partial projection information for the image.

Visit http://terraserver-usa.com/ and locate the area of interest (this URL was active at the time this topic was written). For this example we will zoom into Palo Alto, California and use a USGS aerial photograph taken on October 30,1991. We zoom into the photograph to four-meter resolution for our area of interest. A screen shot showing part of the Terraserver web page is shown below. The arrows have been added to show three prominent landmarks.
We download the image seen above (using a menu on the web page that is not visible in the screenshot) as `palo_alto.jpg` and we also download the associated world file using the name `palo_alto.jpgw`.

Note the features shown by arrows in the illustration. We would like to download an adjacent image showing the region just below the region seen above. To do so, we pan the image downward by clicking on the "South" arrow at the bottom edge of the image on the Terraserver page.
Terraserver will scroll down one image at the current zoom level and show the display seen above. The same three landmarks are marked again with arrows. Note that when Terraserver scrolls to a new adjacent image it leaves some overlap with the previous image. We download this second image as `palo_alto2.jpg` and the associated world file as `palo_alto2.jpgw`.

If we take a look at our downloaded files with Windows Explorer we see that we have downloaded four files: two `.jpg` image files and two `.jpgw` world files. World files are simple text files that may be opened with Notepad.

**Step 2: Import and georegister the images**

Unfortunately, world files are obsolete in GIS usage because they do not encode the projection used. They simply provide certain local projection values and leave it up to the user to manually specify the actual projection in use.

If we opened up one of the world files in Notepad we would see the following for the `palo_alto.jpgw`:

```
8.000000
0.000000
0.000000
-8.000000
574400.000000
4147200.000000
```

...and this for `palo_alto2.jpgw`:

```
8.000000
0.000000
0.000000
-8.000000
574400.000000
4145600.000000
```

... That's all! No mention of any projection used, just the local projection parameters for whatever mystery projection was used. To find the projection used we will have to drill into the documentation posted in obscure places on the TerraServer site and then use the information we find to manually specify the projection information for each image within Manifold.

This is a phenomenally inconvenient way of doing things, which is why the GIS industry evolved the GeoTIFF standard that is now used by over 160 different companies instead of world files. However, Microsoft's TerraServer still uses world files. One suspects they do so because using GeoTIFF would force them to provide the images in TIF format while using world files allows them to serve images in JPG format and thus simplify their download process to simply saving whatever image has already been served to a web browser in JPG.

Be that as it may, if we want to use Terraserver images for free we must deal with world files. Lucky for us, Manifold is a powerful enough tool to cut through the hassles associated with world files. When Manifold imports an image it automatically looks in the folder from which the image was imported to see if there is a similarly-named file that uses one of the typical world file extensions. If such a world file exists, Manifold will extract the information it contains for use with local projection values. In this case, Manifold will find a `jpgw` file for each `jpg` file that contains the world file numbers. See the Importing Images topic for more information.
We import the `palo_alto.jpg` and `palo_alto2.jpg` image using File - Import - Image. If we open the Palo_alto image we see that Manifold has correctly imported the .jpg image we downloaded from the web site.
If we open the Palo_alto2 image we see that it too has been correctly imported.

In both cases, because the world files do not specify projections Manifold has imported both images using Orthographic projection. Because the use of Orthographic is a tip-off to Manifold that the image file format from which the images were imported does not provide full projection information, Manifold has raised an info bar on both images to warn us to verify the projection.

We can verify the projection and georegister the images at the same time, by clicking the info bar to launch the Edit - Assign Projection dialog for the image. We will have to manually specify the projection to be used since the world files do not do so.

The Assign Projection dialog is used to verify the projection if no changes need to be made or, if changes must be made, this dialog is used to specify the correct projection and parameters. We first click on the info bar for the Palo_alto image.

As seen above the dialog shows that the image has been imported using the default Orthographic projection used when no projection is cited by the format used. However, the Local offset and Local scale values have been correctly set to the values contained in the world file.

Check the Preserve local values box so that the local values imported from the world file will be retained when we change the projection to the correct projection.
We now must specify the correct projection. In this case, it is **Universal Transverse Mercator - Zone 10 (N)** and the datum to use is the **North American 1983**. See the notes at the end of this topic to learn how we know this magic information.

Hunt through the hierarchical list of projections in the dialog to find **Universal Transverse Mercator - Zone 10 (N)** and then choose this projection by clicking on it. Choosing a new projection would normally reset the values in the Local offset and Local scale boxes to the defaults for the new projection. Since we have checked the Preserve local values box the local values imported from the world file will not be changed.

After we press OK the image is georegistered. There will be no apparent change in the appearance of the images since georegistration in this case is simply a matter of telling Manifold how to interpret the coordinates it already has.

Repeat the above procedure to verify and georegister the **Palo_alto2** image as well by using the Edit - Assign Projection dialog.

**Step 3: Copy and paste to assemble a larger image**

Now that the images are georegistered the rest is easy.

Open the **Palo_alto** image. This is the "upper" image. Also open the **Palo_alto2** image. This is the "lower" image that overlaps the **Palo_alto** image along the upper edge.
With the focus on Palto, press CTRL-A or choose Edit - Select All to select all of the pixels. Press CTRL-C or Edit - Copy to copy all of the pixels.

Click on the Palto image to move the focus there and press CTRL-V or choose Edit - Paste to paste the copied pixels into this image. Manifold will ask if we want the image enlarged since most of the pixels added by the pasted image fall outside the original Palto image. Press Yes.
The result is that the *Palo_alto* image has been extended downward by the pasting of the pixels copied from the *Palo_alto2* image. The pasted pixels remain selected after the *Paste* operation.
If we click **Select None** we can see that the two images have been assembled into a single, larger image.
Zooming into the image we see that the alignment is excellent. The green lines mark the boundary between the original image and the pasted pixels from the other image. When TerraServer images originating in the same USGS DOQ are pasted together the boundaries are usually invisible.

**Notes**

This procedure uses two images that are vertically adjacent. The same process works when more images than just two are assembled. Import the images, georegister each using the **Edit - Assign Projection** dialog and then copy and paste them together into a single large image. When working with many images or large images, use a machine with lots of RAM, fast processor and adequate free space on disk.

How on Earth did we know that the correct projection to use was UTM zone 10? This resulted from some detective work and from some pure guesswork based on previous experience with USGS data sets. The TerraServer website provides only the following remarks in a discussion of the USGS "DOQ" images from which the TerraServer images are derived.

"The standard DOQ from the U.S. Geological Survey is a black-and-white (gray-scale) or color-infrared image covering 3.75 minutes of latitude by 3.75 minutes of longitude. Thus, four such photos can be combined in a mosaic to cover the area represented by a standard USGS 7.5-minute, 1:24,000-scale topographic map. Using mosaics is easier because images overlap. The DOQ's are referenced to the North American Datum of 1983 and use the Universal Transverse Mercator projection."

The datum in use is obviously the **North American 1983** datum, most likely that for CONUS (meaning the **Continental US**, since that's where Palo Alto is located), but the projection is not as explicit as we would like. The Universal Transverse Mercator projection is not one projection but rather a family of over one hundred projections. Saying an image is in UTM without saying which specific UTM zone was employed is somewhat like saying that an address is located at a postal code without specifying which postal code. It's possible to do some detective work to figure out what postal code is involved for a given street and city but it would be nice to simply have the postal code specified.
It's a reasonable guess that if the DOQs from which the TerraServer images are generated are in some UTM projection than the TerraServer images are also in the same UTM projection. We can also infer that if the DOQs are arranged so that they tile standard USGS 7.5-minute, 1:24,000-scale topographic maps then the DOQs use the same UTM zone employed in USGS 7.5-minute topo maps. If we know the USGS topo map in which the TerraServer image is located, we know the UTM zone used for that image.

The Manifold CD contains a .map file called USGS 24K Index.map that provides an index to USGS 7.5-minute, 1:24,000-scale topographic maps covering the US. We can open this map and based on our knowledge of where Palo Alto is located (it is located conveniently between Mountain View and Menlo Park) we can see that Palo Alto, California, is contained within the Palo Alto USGS topo map. If we didn't know where our images were located we would have to do some additional detective work, perhaps consulting an online atlas or other resources to figure out in which USGS topo map they reside. Using Manifold, we might add a layer of place names to the USGS 24K index map. For the images used in this example the task is easy but in cases where TerraServer images are in rural areas near the edges of topo maps we may have to work harder to figure out in which topo map our images are located.

Once we know the topo map in which our images are located we know the UTM zone they are in. Somewhere on Internet there is probably a list that specifies what UTM zone is used for each USGS topo map. However, there is a faster way to find out what UTM zone our images are in than to hunt all over Internet for some magic list of USGS topo maps and the UTM zone used for each.

We can simply go to the USGS web site and download a 1:24K scale Palo Alto map in SDTS format (USGS calls it an "SDTS DLG" map). We import it into Manifold, open it and look in the Edit - Assign Projection dialog to see what UTM zone is used. Because SDTS format correctly saves full projection information the UTM zone used will be correctly stated. We will see from the dialog that it is UTM zone 10.

![Map of Palo Alto](image1)

It's usually a good idea to download the USGS 1:24K SDTS DLG drawings for the region covered by the images being pasted together. The transportation / roads drawings from the SDTS map can be shown together with the images in a map to verify that georegistration has been correctly accomplished, as seen above.

One other use of copy and paste is to eliminate the small USGS logo that is embedded in each image downloaded from Terraserver. By pasting an adjacent image to the South the region of overlap will cover up the USGS logo with non-logo pixels. This effect can be seen in the example above where the USGS logo in the lower right of the Palo_alto image was covered up by overlapping pixels pasted from the Palo_alto2 image. The image can then be cropped back to the original size and the USGS logo will be gone. The images provided by USGS
are all in the public domain and do not need to be branded with the USGS logo if the user does not so desire. The original USGS DOQ images do not include small logos.

</tbody>
</table>

The Products table has fields for Category ID, Product Name, Unit Price, Units in Stock and various other columns not shown in the illustration above. Each product in the table has a Product ID. We will add two active columns that provide the category name for each product as well as the average price at which the product was sold.

The category name will be found by looking up the Category ID for the product in the Categories table.

### Categories

<table>
<thead>
<tr>

</tbody>
</table>

This table lists all products in all orders. By finding every occurrence of a particular product we can see what the unit price was that was actually applied for that product in the order.

**Step 1: Add Active Column**

Open the Products table and right click onto any of the column heads and choose Add - Active Column.
In the **Add Active Column** dialog.  Provide the name of the function for the **Category Name** column and other parameters as shown above.  The function name used is the name of the function that we will write into the script in the next step.  Press **OK** and the **Products Script** for the **Products table** will be created and opened for editing.

**Step 2: Enter the script**

The script component is set up to use VBScript by default.  To save time, we will enter the functions for both active columns into the script component at this time:

```
' -- determines average price for product using [Order Details] table
Function AveragePrice

    ' -- obtain product ID
    product = Record.Data("Product ID")

    ' -- obtain details of orders for product
    Set details = ComponentSet(ComponentSet.ItemByName("Order Details"))
    Set detailsForProduct = details.RecordSet.EqualTo("Product ID", product)

    AveragePrice = detailsForProduct.Average("Unit Price")

End Function

' -- looks up product category name within [Categories] table
Function CategoryName

    ' -- obtain category ID
    category = Record.Data("Category ID")

    ' -- obtain category name from Categories table
    Set categories = ComponentSet(ComponentSet.ItemByName("Categories"))
    Set catRecords = categories.RecordSet
catRecordIndex = catRecords.ItemByValue("Category ID", category)
    If catRecordIndex < 0 Then
        CategoryName = ""
    Else
        CategoryName = catRecords(catRecordIndex).Data("Category Name")
    End If

End Function
```
**Step 3: Add second Active Column**

Add the second active column by right clicking onto any column head in the table and choosing **Add - Active Column**.

We add the active column called **Average Price**. The function called is the **AveragePrice** function written into the script in the previous step.

After creating the column we right click on the **Average Price** column and choose **Format** and set the formatting to use $ currency formatting.

The result of the above is that two new columns appear in our table which are computed using the functions in the script.

**See Also**
See the Scripts topic for information on scripting. See the Active Columns topic for more on active columns.
Active Columns using JScript

This topic adds three active columns to the Employees table from the Nwind.mdb sample database.

<table>
<thead>
<tr>
<th>F..</th>
<th>Last Na..</th>
<th>First N..</th>
<th>Birth Date</th>
<th>Hire Date</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>Fuller</td>
<td>Andrew</td>
<td>2/19/1942</td>
<td>7/12/1991</td>
</tr>
<tr>
<td>4</td>
<td>Peacock</td>
<td>Margaret</td>
<td>9/19/1957</td>
<td>3/30/1992</td>
</tr>
<tr>
<td>5</td>
<td>Buchanan</td>
<td>Steven</td>
<td>3/4/1955</td>
<td>9/12/1992</td>
</tr>
</tbody>
</table>

The Employees table has fields for Employee ID, Last Name, First Name, Birth Date and Hire Date. We will add three active columns that provide the full name of the employee, the age of the employee and the years since the employee was hired.

**Step 1: Add Active Column**

Open the Employees table and right click onto any of the column heads and choose Add - Active Column.

In the Add Active Column dialog, provide the name of the function for the Full Name column and other parameters as shown above, including choosing JScript as the language to use. The function name used is the name of the function that we will write into the script in the next step. Press OK and the Employees Script for the Employees table will be created and opened for editing.

**Step 2: Enter the script**

To save time, we will enter the functions for all three active columns into the script component at this time:

```javascript
// compose full name from [Last Name] and [First Name]
function fullName() {
    return Record.Data("Last Name") + ", " + Record.Data("First Name");
}

// return number of years since given date to current moment
function years(arg) {
    today = new Date();
    todayYrs = today.getFullYear();
    query = new Date(arg);
    queryYrs = query.getFullYear();
}
```
// return number of years since [Birth Date] to current moment
function yearsOld() {
    return years(Record.Data("Birth Date"));
}

// return number of years since [Hire Date] to current moment
function yearsWorking() {
    return years(Record.Data("Hire Date"));
}

**Step 3: Add remaining Active Columns**

Add the remaining active columns by right clicking onto any column head in the table and choosing Add - Active Column.

First we add the active column called *Years Old*. This active column uses the `yearsOld` function written into the script in the previous step.

Next we add the active column called *Years Working*. This active column uses the `yearsWorking` function written into the script in the previous step.
The result of the above is that three new columns appear in our table which are computed using the functions in the script. Note that two of the functions use the `years` function defined in the script.

See the Scripts topic for information on scripting. See the Active Columns topic for more on active columns.
Show Area of a Parcel in Acres

Manifold features may be easily combined to create a virtually unlimited range of capabilities. In this example we will combine some simple features to report in acres (or hectares) the surface area of a parcel.

For this example we will use the ZCTA Zip Codes sample project.map file. This shows ZIP codes (postal codes) in the US as areas. We will find the acreage of areas.

Step 1: Make sure the drawing is projected

Load the ZCTA Zip Codes.map sample projects. Open the Zt11_District of Columbia drawing.

To compute areas accurately, we must use the drawing in projected form. Using the Edit - Assign Projection dialog we verify the initial projection of the drawing as Latitude / Longitude. Manifold requires us to do this before we can change the projection of the drawing.

Next, we use the Edit - Change Projection dialog to change the projection to Orthographic, making sure to use the Suggest button to suggest appropriate parameters. Projections will use either meters or feet as units of measure in their coordinate systems. Note that the Orthographic projection uses meters as units of measure in its coordinate system.

Any projection which provides accurate measurement of areas would work just as well. See the Guide to Selecting Map Projections topic for a discussion of different projections.
The projected drawing has a slightly different appearance. This is how the District of Columbia would appear in real life if viewed from an aircraft directly above the District.

**Step 2: Show areas in the drawing’s table**

In the **Miscellaneous** section of the **Tools - Options** dialog make sure the **Use English measurement units** box is checked.

Open the drawing's table. In the **View - Columns** dialog, enable the **ZIPCODE** and **Area (I)** columns for display.

<table>
<thead>
<tr>
<th>ZIPCODE</th>
<th>Area (I)</th>
</tr>
</thead>
<tbody>
<tr>
<td>20012</td>
<td>69020717.2976609</td>
</tr>
<tr>
<td>20015</td>
<td>92769003.6535265</td>
</tr>
<tr>
<td>20011</td>
<td>130659981.292517</td>
</tr>
<tr>
<td>20008</td>
<td>84789312.0459514</td>
</tr>
<tr>
<td>20016</td>
<td>125734696.95095</td>
</tr>
<tr>
<td>20017</td>
<td>63914572.4810944</td>
</tr>
<tr>
<td>20018</td>
<td>87222502.3952926</td>
</tr>
<tr>
<td>20010</td>
<td>43557760.6244952</td>
</tr>
<tr>
<td>20011</td>
<td>191081661.803211</td>
</tr>
<tr>
<td>20009</td>
<td>37223355.8283784</td>
</tr>
<tr>
<td>20001</td>
<td>72836196.4501965</td>
</tr>
<tr>
<td>20007</td>
<td>94927481.9962765</td>
</tr>
<tr>
<td>20002</td>
<td>141327436.870931</td>
</tr>
</tbody>
</table>

The table now reports the area of each object in the drawing in the **Area (I)** **intrinsic field** column, using square feet as the units of measure. It uses square feet because we checked the **Use English measurement units** box in the **Tools - Options** dialog; if this box were not checked, then the **Area (I)** intrinsic field would report the areas as square meters since the Orthographic projection uses meters as units of measure.

At this point we already have our results. We can select any area in the drawing and the row corresponding to that area will also be selected in the table. We can then see the surface area of that area object in square feet listed in the **Area (I)** column. Divide that value by 43560 to get the surface area in acres (one acre = 43560 square feet).

From this point onward we can do a few additional steps to increase the user friendliness of finding areas. For example, we can make the selection more obvious in the table.

With the focus on the table, press in the **Selection Filter** button. This will cause the table to show only selected records.

4121
If no area is selected the table will appear empty.

Using touch select, select an area in the drawing.

The record for the selected area will appear in the table. With the Selection Filter button engaged, it is easy to resize the table window so that it occupies a small portion of the display, allowing a larger drawing window. We can then click at will on different areas in the drawing window to select them and immediately see their surface area in square feet.

**Step 3: Automatically compute acreage**

It would be more convenient if Manifold calculated the surface area for us in acres. This is easy: we can use an active column to automatically convert square feet into acres.
Right click on any of the table's column headings and choose **Add - Active Column**. In the resulting dialog we specify the characteristics for the new active column. We will use **Acres** for the name of the new column. It will be a **Floating-point (double)** type that will be computed **on user request**. Press **OK**.

Creating an active column means creating a script that implements the functionality of the column. To make this easier, Manifold helpfully creates a new script populated with some text to use as a starting point.

We edit the starting text as seen above.

```
Function Func
    Func = Nothing ' Record.Data("Column")
End Function
```

```
Function Func
    Func = Record.Data("Area (I)") / 43560
End Function
```
The function we have created tells Manifold to take the value from the *Area (ft)* column for each record and to divide it by 43560. This will convert square feet into areas. If we preferred some other measure, such as hectares or square miles or square kilometers we could have just as easily used the conversion factor to those from square feet instead of 43560.

Back in the table, we right click on the *Acres* column head and choose *Recompute* (note that we right click on the column head). The *Acres* column now reports the surface area of that area object in acres.

When we created the active column we could have instructed Manifold to recomput the column automatically by choosing a different setting in the *Compute* box in the *Add Active Column* dialog. That is not usually done in applications like this because area objects in drawings are not usually continuously changed, so there is no point to frequent recomputation of surface area. It’s enough to do it once, on demand, as necessary.

We now have a very useful arrangement. Every time we select a different area object in the drawing...
The table will immediately report the surface area in acres.

One very useful aspect of active columns is that they work just like any other table column. For example, now that we've defined an active column we can see the value of it for any object by simply double-clicking the object to call up the Object Fields dialog.

We have to press in the r/o (Show Read-Only) button to show the Acres column because it is a read-only column. Together with viewing selected records in the table this gives us a second way of seeing the acreage of any area object in the drawing.

**Step 4: Create a ViewBot**

Yet a third way of displaying acreage is to create a ViewBot that shows the total acreage of all selected areas. This is easy to do.

Choose View - Panes - ViewBots to turn on the ViewBots pane.
Choose New ViewBot to add a ViewBot to the pane.

In the Add ViewBot dialog we choose the [Selection] as the scope, the Acres column as the source of our data and Sum as the operation. This tells the ViewBot to report the sum of all values in the Acres column for all selected records. The Caption is whatever text line we want to remind us of what the ViewBot is telling us. We choose to Autorefresh to make sure the ViewBot is always up to date when the selection changes. Press OK.

The ViewBot immediately reports the total acreage for the selected area object.
If we click on a different area in the object to select it...

...the ViewBot immediately reports the acreage for that object.

What is very useful about our new ViewBot is that we can select several area objects (using Add to Selection)...
...and the ViewBot will report the sum of the acreages in all the selected area objects. This allows very rapid interaction with the drawing. We can very rapidly add or remove areas from the selection to see exactly how they sum up in acreage. In fact, we can easily save various selections as saved selections, create new selections and so on to use this capability for a sort of manual territory balancing or other interactive work.

If we have the table window still open, note that it continues to show selected records. We can use the ViewBot to see the sum of the acreages and the table to see values for individual records. Outstanding!

ViewBots are such a useful tool that we can add a few more to the ViewBots pane.
We will add a ViewBot that reports the largest parcel in the selection.

We will add one to report the smallest parcel in the selection.

And finally we would like to know the average acreage of parcels in the selection.
We now have a wonderfully interactive display that allows us to select whatever we like and immediately see the total acreage as well as the largest, smallest and average parcel acreages. Outstanding!

Notes

The ViewBot and table will continue to report values for selected items no matter how selection is accomplished. For example, we can select objects using queries or via the Query Toolbar or by other methods. Whatever is selected by whatever means, the ViewBot and table will faithfully report the acreage.

Exporting KML to Google Earth

This is a long topic because it shows every detail for beginners. An experienced Manifold user could do this topic in about five minutes.

Google users may find it odd that this tutorial is written using Microsoft Virtual Earth to provide imagery backgrounds instead of Google Earth. The substitution of Microsoft Virtual Earth images for Google Earth images was done at Google's request to ensure that the numerous images that appear in this topic when it is posted to the manifold.net website do not show what Google regards as copyrighted imagery. See the note at the end of this topic for more information.

The Tutorial

This topic shows how to open the base map project and how to zoom into a location. We then add points showing the locations of our favorite restaurants and we export the points to Google Earth. The topic assumes that the StarterPack.zip file has been downloaded and installed, that the computer has an Internet connection and that Google Earth has also been installed on the computer.

The StarterPack.zip file contains a starter .map project as well as DLLs for open source image server drivers, including a Microsoft Virtual Earth image server driver. It should be unzipped into the Manifold System installation folder (C:\Program Files\Manifold System by default). If you have not downloaded and installed the StarterPack.zip file this tutorial will not make any sense because the US Base Map.map project file it mentions will not be available to you.

The StarterPack.zip archive must be downloaded from links on the manifold.net web site or from whatever web site you prefer to get your Manifold open source modules.

Note: The usage of Microsoft Virtual Earth image servers, as seen in this tutorial, requires installation of open source software written using the Manifold Image Server Interface. There are many third parties providing free image server modules for image servers like Microsoft Virtual Earth, Yahoo! Maps and others. You can even write your own! Manifold does not supply or support such third party software, but it is really, really cool to know that you can do such things with Manifold and that there is an active open source community supporting Manifold.

The StarterPack.zip archive provides open source software that was contributed to the Manifold user community. The base map was created and contributed by Manifold users as well. The amazing thing is that you don't need to know anything about Manifold internals to do such stuff, nor do you have to have more than ordinary user skills to create things like the base map.

Step 1: Open the base map project

In Windows Explorer, browse into the Manifold System installation folder (C:\Program Files\Manifold System by default) and double-click on the US Base Map.map project file.

Manifold will launch. If this is the first time you have launched Manifold, an Activation dialog will pop up. You must enter at least the Manifold System serial number that was sent to you with your license. If it is longer than 30 days from the date the serial number was issued, you must activate your license as well. See the Activation Keys and Serial Numbers topic in Help.
Manifold launches with a Project pane open on the right that lists all components in that project. There are no windows open in the workspace. The main menu appears at the top and toolbars appear just below the main menu. The illustration above has been reduced.

If we take a closer look at the project pane, we see that each component has an icon next to it depending on what it is. Drawings have a little pencil in the icon. Images have blue lines in the icon, like raster lines on a monitor. Items that linked in from some external data source, like a database or a web server have a little yellow database cylinder in the icon. Comments have a book.

All these items can participate as layers in a map. There is only one map in this project, called "Map" so that beginners don't have to guess what it is. Double click on Map to open the map.
Example: The “Local” tool tip that pops up for many items in the project pane is Manifold's way of telling you that item is stored locally, inside the project .map file. Items also can be linked into a project from elsewhere, just like the linked images from the Microsoft image servers. In that case, the data for those items is not stored inside the project file.

When the map pops open Manifold automatically pops open a default set of toolbars for use with that map and adjusts the main menu with appropriate entries. A map window can be resized and moved around in the Manifold workspace. We can pop open as many windows as we like in the workspace. If we like, we can right click on the Map item in the project pane and choose Open in New Window and Manifold will merrily pop open that same item in a second window for us. That second window can be panned and zoomed independently of the first.

It's not easy to show the entire Manifold workspace in a tutorial like this without using reduced images that are difficult to read. From here on, this tutorial will not show the entire workspace but will just show the main windows as needed in full size illustrations. Let's take a closer look at the map window that we've just opened.
There, that's better! The beautiful background image we see has been browsed automatically for us from Microsoft Virtual Earth. A hallmark of Virtual Earth is the superior, smooth, beautifully realistic quality of the image even at larger scales, as though we are actually hovering over the planet and viewing the scene in real life. The equivalent Google image, which we are not allowed to show you, appears as a patchwork mosaic of annoyingly varied tones without the sense of true reality conveyed by Virtual Earth.

A map window shows a stack of other items as layers. The layer tabs at the bottom of the map window show what layers are in the map and which layers are turned on for display. A layer tab with disabled text means that layer is not turned on for display. In the illustration above, the Drawing layer and the USA layer are turned on.

The Drawing layer is empty (for now) and the USA layer just shows outlines of states in the US using green lines.

The Drawing layer tab has a white background. This is the active layer, the one in which any editing commands will take effect. Click on a layer tab to make that layer the active layer. Double-click a layer tab to turn it off or on for display.

In this example we will add a few points to the Drawing layer and then we will export the Drawing layer as a Google Earth KML file. All the other layers in the map are just there in case we want to use them as reference points or to otherwise help us draw whatever we want into the Drawing layer.

There are too many layers in this map to show all of them at once as layer tabs, so we can use the scroll buttons in the lower left of the map window to scroll through the layer tabs. There is one more layer that is turned on for display, the Virtual Earth Satellite Image layer. This layer automatically fetches an image from the Microsoft Virtual Earth servers at the required zoom and resolution.

**Step 2: Open the layers pane**

The layer tabs are very handy for simple maps, but when maps have very many layers it is usually easier to work with layers by opening the Layers pane.
We open the Layers pane by choosing View - Panes - Layers from the main menu.

The layers pane pops open by default underneath the project pane. It will be too small to show all the layers initially, so we can resize the pane by clicking and dragging on the boundary between the layers pane and the project pane as seen above.
The layers pane shows all the layers in whatever window has the focus (that is, the last window we clicked on) in the workspace. A checked box indicates that layer is turned on for display. We can turn layers off and on by un-checking or checking their boxes.

The map window now shows the **Virtual Earth Satellite Image** layer as the lowest layer, "behind" all the other layers.
Un-checking the **Virtual Earth Satellite Image** layer box in the layers pane will turn off that layer.

The result in the map window is the **USA** layer seen by itself against the default white **Background** layer.
Back in the layers pane, let's check the **Virtual Earth Street Map Image** to see what that is all about.
It appears in the map window. Note that the USA layer is still turned on. The USA layer just contains lines with "empty space" between the lines. Any layer below the USA lines will show through the empty space.

The Microsoft image servers basically have two modes of operation as a web service. They can show street maps like the Virtual Earth Street Map Image layer or they can show mosaics of satellite photos like the Virtual Earth Satellite Image layer. The starter base map contains both as layers because sometimes it is more convenient to use a satellite image as a background and some times we would prefer to use a street map image.

**Step 3: Zoom into a desired location**

In the layers pane, please un-check the Virtual Earth Street Map Image layer checkbox and check the Virtual Earth Satellite Image layer checkbox so that the satellite image layer is displayed. This step is not illustrated.

Let's now zoom into a region of interest. For that, we will use the Zoom Box tool.
Click on the **Zoom Box** tool to make it the command mode for the mouse. Until we unclick the tool, the mouse will be in **Zoom Box** mode when we use it in the map window.

We're going to go to Palo Alto, California, so we'll click and drag open a zoom box around the green squiggles that indicate San Francisco Bay, on the California coast. [Readers who don't know which state is California without a label should be ashamed, deeply ashamed... It's not like it's a hard state to remember, like one of those square states in the middle that all look alike! ]
Manifold zooms in for us and automatically fetches higher resolution imagery from the Virtual Earth server. Let's zoom farther into the San Francisco Bay region.

Excellent. Let's do that one more time, using the **Zoom Box** about where we think Palo Alto is located.
Manifold keeps loading ever more detailed imagery from the Microsoft Virtual Earth server. The problem now is that we’re not sure exactly what we are looking at. There’s a bridge there, but darned if we’re not exactly sure where to zoom now. Now is a good time to switch to using the street map image.
In the layers pane we un-check the Virtual Earth Satellite Image layer and we check the Virtual Earth Street Map Image layer.

In the map window we can see we zoomed into a region too far northwest. We've zoomed into San Mateo and Hillsborough, and not Palo Alto. That's easy to fix.
Click on the **Grabber** tool to make that the command mode for the mouse.

In the map window, click in the lower right corner and then drag to the upper left and release. We are telling Manifold to grab the portion of the view from the lower right corner and move it up to the upper left part of the window. This scrolls the entire window in the desired direction.
Manifold obliges, scrolling the window as we wanted. There's Palo Alto near the center of the display.

We click back onto the **Zoom Box** tool and then zoom into the Palo Alto section of the map.
We keep zooming until we reach the downtown portion of Palo Alto where dozens of restaurants cater to Silicon Valley yuppies and Stanford University students and faculty. Stanford is about a half mile out of view to the lower left in the above map.

**Step 4: Add a point**

We are now zoomed into the map and are ready to add some points that show the locations of our favorite restaurants.

Before we continue, if you have been fooling around with the map outside of the sequence of steps in this tutorial, click on the **Drawing** layer tab to make sure it is the active layer. We will be adding points to the **Drawing** layer.

Next, a little housekeeping: We are going to turn on **Instant Data** mode so that when we click to add a point we can easily also add some data for that point.

We do that in the main menu by clicking **Edit - Instant Data**. This puts a check mark next to the **Instant Data** entry on the menu to let us know that **Instant Data** mode has been turned on. We'll see what this mode does in an instant.
To begin adding points we click the **Insert Point** tool in the drawing toolbar. This puts the mouse into **Insert Point** command mode.

Position the cursor at the corner of the intersection of University Avenue and High Street as seen above and click.

If we didn’t have **Instant Data** mode on, a dot would have instantly appeared. If we just wanted to do something really simple and click to create points we could do that all day without using **Instant Data** mode. But because we’re using Manifold and not some retarded “sketch” program, we want to do more than just click and create dots. We want those dots to be connected with some data, like the names of restaurants, that Google Earth can then use as a label or a description. Using **Instant Data** makes that especially easy to do.

With **Instant Data** mode turned on, a dot appears and a dialog pops open that allows us to enter data for the point. The dialog pops open with a field already opened and the text cursor in the box ready for us to enter text.

All drawings in Manifold have a table that’s connected to that drawing. Every object in a Manifold drawing, that is every point, every line and every area, has a record in the drawing’s table. Tables can have all kinds of data fields in them. It’s a cool way of having data associated with things we see in a drawing, like points.

The drawing called "Drawing" in this project has only two fields in its table, as that is how it was created when the starter map project was made. These are called **Name** and **Description**. It takes only a second or two to add fields or otherwise change the structure of a table. For now, we’ll use the table as is.

With **Instant Data** mode turned on Manifold immediately sets us up to add data whenever we create a new object. In this case we clicked using the **Insert Point** tool to create a point, so Manifold pops open the dialog to allow us to enter the data we want associated with that point.
We enter the name **Miyake** for this point and we enter the URL for this restaurant into the description field. Press **Enter** or click **OK**.

A new point appears using gray default color and default size. That gray color is boring, so let's change the color to bright green.

We do that by clicking on the **Point Background** color well..
Examples

...and choosing a nice bright green color.

The point appears in bright green. This particular point style (shown in the Point Style well that's just to the right of the Point Background color well we changed) uses foreground color for the border of the circle and background color for the fill color. If we wanted the points to be bigger we could click the Point Size well and make the size larger than the default size of 3.

There are two interesting things to note about the above illustration: first, by default the format color settings apply throughout an entire layer. When we make the Point Background color bright green, all points in that Drawing layer will be bright green. There are ways of changing this so that different points have different colors but since this is a beginner's tutorial we won't get into that.

The second interesting thing is that Google's first Palo Alto offices were about 100 feet to the lower right of that green dot in the illustration above. What is now one of the most valuable businesses in the planet started in cramped, second floor offices behind a video rental store near that green dot. Even more interesting is that the original offices of Facebook are just across High Street from the green dot. Amazing! ...Over one hundred billion dollars in wealth created on either side of a small sushi restaurant in Palo Alto.

**Step 5: Add another point**

Let's add some more restaurants.
The mouse is still in **Insert Point** command mode, so we will click on the corner of Emerson Street and University Avenue.

**Instant Data** mode is still on, so the dialog pops open again. **Instant Data** repeats the last data entered and positions the cursor within the last entered box ready to go. This is a big help with repetitive data entry. For example, if a city employee were marking the locations of different types of city assets and marking all hydrants, it is a real time saver to not have to manually type "hydrant" thousands of times.
In this case, we're marking the location of a sushi restaurant that does not have a web site so we'll just enter **Japanese** as the description...

...and then enter the name of the restaurant in the **Name** field. Press **Enter** or **OK**.
Manifold creates a new point at the location clicked. Note that since formatting works by default for all objects in a drawing, all the points in this drawing layer will be green, use the same style and be the default point size of 3.

We can continue to add as many points as we like. The above procedure is very fast, so it's easy to add points. It's also easy to add URLs. We like to keep an Internet Explorer browser session open so that we can find the URLs for those restaurants that have a web page. We can then Copy the URL from the browser window with a CTRL-C and then switch into Manifold and Paste the URL into the Description box with a CTRL-V. Fast and easy!

**Step 6: Correcting errors**

Suppose we get a little too excited about all this and click to create a point in the wrong spot? There are two ways of dealing with this.

Consider the point shown above with a red arrow. We accidentally added it in the wrong location. The first way to remedy the error is to select the point and delete it and then create a new point in the correct location.

Choose the **Select Box** tool.

Click and drag to make a selection box around the point. The **Select Box** tool selects all objects that are entirely within the box.
The point is shown using red selection color for foreground color to show it is selected.

If we choose **Edit - Delete** in the main menu or press the **Delete** key the point is deleted. For that matter, we could also have chosen **Edit - Cut** or **CTRL-X** to use Windows **Cut** to delete the point and simultaneously copy it to the Windows Clipboard. (Yes, Manifold can copy objects into the Windows Clipboard. These can then be pasted as new drawings or pasted into other drawings.)

Suppose, however, that we’ve entered some really long text into the **Description** box and we don’t want to re-enter it. In that case, instead of deleting the point we can just move it to the desired location.

To do that, we first make sure the mouse is not in any command mode. For example, if we have the **Insert Points** toolbar button pushed in, we first click it out. When the mouse isn’t busy with some command mode it can be used for **smart editing** in Manifold, that is, a streamlined, simple, default editing regime.
**CTRL-ALT** click on the point to be moved. That is, while holding down the **CTRL** key and the **ALT** key, click on the point.

This selects the point for editing, and a square box editing handle appears at the point's location. The editing handle can be clicked and dragged, moving the object as well.

We can click and drag the point to the desired location.

After we release to move the point to a new location, it still stays selected for editing in case we want to do anything else with it.
Deselect it by clicking the Select None button. (There are many other shortcuts which we will not get into here).

The point appears in its new location at the corner of Ramona Street and Hamilton Avenue. Many Google employees will immediately recognize this as the location of the Osteria restaurant, a great spot for osso buco with a nice Chianti classico.

**Step 7: Preview our work before export**

So far we've added points using Virtual Earth street map imagery as a background. That's very cool and useful but it is not the satellite imagery used by default in either Virtual Earth or Google Earth.
If we show the entire map window again, we can see that several additional restaurant locations have been added. Each one also has had a name and description provided. Let’s see how these points appear with a satellite image background.

In the layers pane we uncheck the street map image layer and check the satellite image layer.

OK, that’s very cool. The green dots are harder to see with all that photographic imagery clutter (easy to fix, see below) but the screenshot above shows us how Manifold can preview what will appear in Google Earth by using satellite imagery from image servers, in this case using imagery from Microsoft.
This is also a chance for us to move points around using the photograph as a visual reference instead of the street map image. If a point appears, say, in a parking lot just next to a restaurant instead of on the building itself we could move it using the procedure given above.

This is one reason why it is so valuable to prepare KML files in Manifold, because you can see where the data is going to appear using either street map imagery or overhead aerial photos like the one seen above.

Now would be a good time to save the project using **File - Save** to some safe location.

**Step 8: Create a Google Earth File**

Actually creating a Google KML or KMZ file from our drawing is absurdly easy.

We right-click on the **Drawing** in the project pane and in the menu that pops up...

...we choose **Export**.
In the Export Drawing dialog that pops open we choose KML / KMZ Files in the Save as type box and we provide a file name. If the file name we provide ends in .kmz Manifold will create a KMZ file. If the file name ends in .kml Manifold will create a KML file. The two are the same thing except that KMZ is a compressed form of KML using “zip” style compression.

For this example, we create a KMZ file using the name sample restaurants.kmz. Press Save.

The Export KML File dialog pops open to allow us to choose which fields we want to use for Google Earth Name and Description fields.

The pull down boxes for the Name and Description fields show all the fields available in the drawing's table, including all sorts of weird internal fields that are used by Manifold experts. We ignore all those and simply choose the Name and Description fields we have used to store restaurant names and descriptions. The Drawing layer in the starter project uses these two names for the fields it contains to make life easier for beginners. Press OK.
If we pop out of Manifold and take a look with Windows Explorer, we see that Manifold has created a new file for us called **sample restaurants.kmz**. We can double-click this file to launch it in Google Earth.

Google Earth will fire up, do the "zoom in from space" thing and, Voila! There are our points. Note that Google Earth by default will take the contents of the **Name** field and use it to label each point. Note also that the imagery used by Google Earth is indeed just like the satellite imagery the image servers streamed into Manifold as the background for our map.
The Google Earth Places pane shows both the Name and the Description values for each point. We obviously didn't have a lot of URLs for the restaurants of interest. What's cool about this Places pane is that if you do have a URL as the description, clicking on that URL in the Places pane will launch it in a mini-browser in Google Earth.

There are many ways of using URLs. For example, suppose we snapped pictures of each restaurant and then uploaded them to a public photo viewing site. For each restaurant we could put the URL to the photo in our drawing's Description field and then it would have been uploaded to Google Earth so that people could click to see what the restaurant looks like. This would be especially useful if our business was real estate sales and we were marking locations of houses for sale as opposed to our favorite restaurants.

**Step 9: Useful Manifold Features**

There are thousands of Manifold features useful in various situations. Here are a handful out of those thousands.

**Opacity:** Suppose we don't like the visual clutter of the photographic image in our map but we still want to have it available as a visual guide in the background. That's easy to do by adjusting the opacity of that image layer.
In the layers pane we click the **Opacity** button to turn on the **Opacity** column in the pane. This shows the opacity (that is degree of transparency) for each layer. We double-click into the **Opacity** cell for the **Virtual Earth Satellite Image** layer and change it to **40%**.
The result is that the layer fades out as part of the white background layer shows through. This makes it easier to see the points.

**Labels:** Suppose we have trouble remembering which green dot is which restaurant and we would like to add labels in the Manifold map, one for each point that gives the **Name**. That's easy also:

1. We right-click on the **Drawing** component in the project pane and we choose **Create**.

2. In the **Create** menu that pops up we choose **Labels** to create labels.
In the Create Labels dialog that pops up we choose a name for the new Labels layer we are creating.

To create the text automatically for each label, we double-click on the Name field in the Columns pane. That adds it to the Text box to be used as the text for each label. Press OK.
This creates a new labels component, called **MyLabels** just as we wanted, in the project pane. It is shown indented under the **Drawing** drawing because it is created automatically using the data in that drawing's table. To add this layer to the map we drag and drop it into the map.

First, we click on the **Drawing** layer tab in the map to make it the active layer. Now, when we drag and drop the **MyLabels** layer from the project pane into the map it will appear just above the **Drawing** layer.

Using the mouse, click on the **MyLabels** item in the project pane and then drag the mouse cursor over into the map window and release.

The **MyLabels** layers pane appears in the map window as a new layer and the labels appear using default formatting, positioning and font. It's a big uglier than we would like.
For starters, we would like to change positioning so that instead of being on top of each point the labels are below and to the left. This is easy to do.

When a labels layer is the active layer in a map, Manifold configures the toolbars with controls for labels. We can change the alignment settings (seen above) from centered to appearing to the left and below.

That's better. However, it would be cool if we could adjust the formatting of the labels so that they use black text with a bit of white outline color for better legibility.

To do that we click on the Label Style well in the formatting toolbar.
We choose a style with a bit of background color.

We then click into the **Label Background** color well...

...and we change the background color to white.
The result is a subtle change but highly useful when labels are to appear before a background that varies in color from light to dark. Note that these label changes appear within the Manifold project. Google Earth uses its own fonts, so these changes are not exported into Google Earth. But they are nonetheless highly useful because if we want to manipulate sophisticated data within Manifold we will often want to use labels in sophisticated ways to help keep our bearings.

**Changing Data for Descriptions:** Suppose we would like to update the data for each point, say, by changing the description? That’s easy to do by editing the drawing’s table.

Double-click the drawing’s table to open it in a table window.
There’s the data we entered for each point. We can change a value by double-clicking into the cell.

Here we’ve changed the name of Pizza My Heart to Pizza A Go Go, the name under which they do business for deliveries. We’ve also changed the Description for that record to include a totally off the wall and useless reference to the manifold.net home page.

The changes take immediate effect in the Manifold project. For example, the label for that restaurant (which automatically uses text from the Name field) instantly changes to show the new name. Note, by the way, that Manifold by default will "clip" labels that get in the way of each other. This can be turned off if desired.
If we export the drawing to a kmz file and open that file in Google Earth, we see that the new name is now used for a label in Google Earth. Google Earth doesn’t like to clip labels, and will try to move them around to show as many as it can no matter what.

In the above case, Google Earth tries too hard to show all labels because it has moved the Sushi Tomo label to the right and the Pizza A Go Go label to the left when in reality the two points are on opposite sides of the street the other way around.

If we zoom farther into Google Earth so there is more room for labels then Google Earth will show the labels in correct position nearer to the actual points they label.
The description in Google Earth's Places pane has also changed. Note that Google Earth is smart enough to know a URL when it sees one, so we can embed URLs within other description text and still be able to launch the URL with a click.

Notes

Why Palo Alto in the example? That's where Stanford University is located and where Google was founded. The restaurants mentioned are all places our friends at Google know. It's also amusing that the surprisingly muscular new CloudMade startup which is challenging Google Maps by leveraging the community intelligence of the OpenStreetMaps project is right next door, in Menlo Park.

Isn't there a faster way of finding a place in Manifold than using Zoom Box? Sure. If you have the Geocoding Tools extension installed you can GoTo an address, city name, ZIP code, etc. Even without the Geocoding Tools extension you could select a city name using the selection toolbar and then jump to that selection. There are often very many ways of doing something in Manifold so that an experienced user can always pick a method that is just right for the job.

It's fun to export points, lines and areas and to extrude them into 3D shapes. Extruding areas is a great way to make simple "buildings" that will appear in 3D when Google Earth is viewed with an inclined view. See the Export Drawing - KML, KMZ topic for an illustration.

Legal Note

This topic originally used Google Earth imagery because our writers felt that people interested in exporting KML to Google Earth would probably feel most comfortable with Google Earth imagery as the background layers used to create such KML. Makes sense, right?

However, Google lawyers (much to the horror of some of our technical Google friends) contacted manifold.net to complain that Google Earth imagery was being shown on the Manifold web site, including within this topic in the web version of Help. Google complained such images showed no Google watermarks or copyrights. Google commended our support for KML but objected to illustrations showing Google imagery. Bizarre, but true.

Because this user manual automatically gets published to the web, the only way to assure that Google imagery does not get published is not to use Google imagery in the screenshots. We have therefore replaced the background imagery from Google Earth in this topic with imagery from Microsoft Virtual Earth. It is a crazy world when Google lawyers convince software developers to feature Microsoft products instead of Google products, but that's the way it is.

As it turns out, Microsoft Virtual Earth actually works better in such applications than Google Earth, so using Virtual Earth in this topic makes most images look better.
Microsoft Virtual Earth imagery is very similar to that produced by Google Earth with several notable improvements: Microsoft Virtual Earth imagery has no “throttles” in it like Google to prevent active usage, it is not artificially disfigured with watermarks, it provides a far smoother and more realistic appearance in larger scales and in many cases it is more detailed than Google imagery. These are such significant benefits that most Manifold users have switched to using Virtual Earth for KML authoring even if the ultimate target of their authoring efforts is Google Earth.

Microsoft Virtual Earth is also very convenient because it is widely available within other geographic browsers besides Google Earth. For example, a plug in for NASA World Wind allows use of Virtual Earth in World Wind. Since KML/KMZ format is now used in very many applications besides Google Earth, it could be that a consequence of Google’s bizarre lawyering is that Microsoft’s Virtual Earth ends up being the de facto standard for image registration for KML files in all applications, even Google’s.

In any event don’t let the antics of lawyers distract you from having fun creating KML files for export to Google Earth and other applications. Whatever source you choose to use as background layers when authoring KML, it’s easy to create dramatic and useful KML files with Manifold as this tutorial shows.

Other Examples
In addition to the examples set forth in the Examples topics, there are additional small examples within various topics throughout this documentation.

- **Color a Map**: Color a drawing using the Color dialog so that no two adjacent areas have the same color.
- **Selection in Drawings**: Using selection modes to select areas, lines or points.
  - **Selection Filter in Tables**: Use the Selection Filter command to show only the selection in tables while a selection is made in the table’s drawing.
- **Formatting Drawings**: Format a drawing using the format toolbar.
  - **Use Thematic Formatting to Show Territories**: Apply thematic formatting to show territories in a map that are named with text strings such as “Great Lakes” and “West Coast.”
  - **Thematic Formatting Example**: Change the size, color and style of points based on the contents of a data field.
- **Copy and Paste**: A geographic example using copy and paste within drawings.
- **Creating Areas**: Adding new areas to a drawing by drawing free hand.
  - **Autocomplete with ALT**: Create new areas or lines that exactly match the edges of existing areas or lines.
- **Editing using Smart Mouse Moves**: Move and reshape areas in drawings using smart mouse moves.
  - **How to Print**: A step by step example showing how to print using a layout, including saving a layout to a PDF file.
  - **Creating a multipage layout**: A step by step example showing the creation of a multipage layout suitable for use with map books, including an example showing how to create marginal notes citing the page numbers of adjacent sheets.
  - **Hyperlinks**: Use hyperlinks to show Congressional web pages by double clicking in a drawing.
- **Editing with Snap**: Reshape areas and move points to exact positions using Snap.
- **Reposition with Snap**: Reposition labels to the intersections of grid lines using Snap to Grid.
- **Tracing Example**: Small example drawing lines over an image.
- **Freehand Tracing**: Create an area object in the shape of Africa in a drawing layer using an image layer as a guide.
- **Create a 20 km Buffer**: Use the transform toolbar to create a border buffer zone that extends 20km.
- **Spatial Overlays and Voronoi Cells**: Given many sampling stations and a few data collection points, assign each sampling station to the nearest data collection point.
- **Transfer Values from Points to Areas that Contain those Points**: Use spatial overlays to transfer values from points to areas that contain them. A typical usage would be to sum up populations in cities within various provinces to get the total population for each province.
- **Show a 3D label in a terrain**: Show labels as 3D objects that float over a terrain.

About the Sample Images

This documentation uses several sample images as examples in various topics.

The bronze sample image shows the equestrian statue of Henry IV (1553 - 1610) that stands at the Place du Pont Neuf just above the Square du Vert-Galant in the romantic heart of Paris.

Henry of Navarre became the first Bourbon king of France in 1589 at the age of thirty-five when his predecessor, Henry III, was assassinated. After a life of great difficulties as well as immense accomplishments Henry IV was assassinated on Friday, 14 May 1610. He was killed by a demented man who stabbed the king twice after leaping onto the royal coach when it was slowed by traffic congestion. (The king had previously escaped another assassination attempt in 1594 when a law student had attempted to stab him at the Hotel de Schomberg.)

Henry IV completed the Pont Neuf, which was begun during the reign of Henry III. He had become king under trying circumstances without the acceptance of the population but during his reign had won the hearts and minds of the French people. Henry IV proved to be a master of practical politics and directed the expansion of French power in Europe and overseas in North America. His support for exploration yielded discoveries such as Lake Champlain. At home, the king supported arts, learning and architecture. He died a beloved king, especially among common folk. Historians have long regarded him as one of the greatest of French kings.

The first equestrian monument to Henry IV was placed at the Pont Neuf by his widow, Marie de Medici. It was smashed by a revolutionary mob in 1792. In 1818 the next generation wished once more to remember the great king and emplaced the current monument. The Henry IV we see today was poured using bronze taken from the statue of Napoleon that was removed from the Vendome column.

The schloss image shows the famous Neuschwanstein castle built by Bavaria's King Ludwig II (1845 - 1886) between 1869 and 1886. "Schloss" is a German word used for castle or chateau. Ludwig II was a man obsessed with romantic images of a medieval Germany that never was. He squandered his fortune building elaborate and expensive fairy-tale castles. The unfinished Neuschwanstein was the last and most dramatic of all.
Set where the Bavarian plain meets soaring Alps, the castle perches within a dramatic landscape of vertical crags and plummeting gorges. The photograph was shot from the Marienbrucke footbridge that vaults over a waterfall in the mountains above Neuschwanstein.

Although it is built in the imagined style of castles of medieval times, Neuschwanstein was created in the late 1800's as a dream castle for Ludwig II's personal fantasies. It is not a practical fortification even though it is sited at highly defensible location once occupied by a true, fighting castle. Numerous design themes within the interior recall epic sagas and themes from Wagner's operas. The interior is only partly completed with sumptuous rooms for the king's apartments (including an artificial cave), a Singer's Hall for musical performances and a breath-taking throne room.

The king stayed at Neuschwanstein for but a few days during the latter stages of construction. In 1886 he was beset by creditors and facing bankruptcy when a Bavarian government commission declared him mentally deranged. A delegation sent to Neuschwanstein convinced him to leave the castle on 12 June and return to Munich for treatment. The next day, the king and his personal physician, Dr. Gudden, both were found dead in the Starnberg See, a large lake on the route from Neuschwanstein to Munich. An inquiry failed to reveal whether the deaths were an accident, suicide or murder.

The Free State of Bavaria now owns Neuschwanstein and operates it as one of Bavaria's most popular tourist attractions. In life a distant and lonely man, in death Ludwig II has become a Bavarian pop icon.

The globe image shows the elevations of the entire Earth using a false color palette to code height. The data used originates in the Global Land One-km Base Elevation ("GLOBE") project at NOAA. The GLOBE project created a one kilometer gridded digital elevation database for the entire Earth.

Several hundred megabytes of data were downloaded from the GLOBE web pages to build a worldwide digital elevation database. This data was then interpolated into a lower resolution data set suitable for casual browsing and background map image generation. This lower resolution data set was then imaged using RasterLab, an internal development tool that was created at manifold.net and used for development and verification of the raster algorithms employed within Manifold System.

The height palette used in the sample image provides relatively low contrast. This image was deliberately selected for use as a sample so that the effects of various image-enhancing commands could easily be seen.
The SanFran image is a sample Landsat 7 image downloaded from a USGS web site as a .jpg image. This is path 44, row 34 using Band 3, 2, and 1. Composition of Landsat bands into a .jpg format image was done by USGS. Date of acquisition is not known but is believed to be spring of 1999. The image shows the spring runoff from the Sierra Nevada mountains and other neighboring mountains into San Francisco Bay and out into the Pacific.

Clearly visible are the numerous regions and famous landmarks of this fascinating area. In the upper right is the Delta, the confluence of the Sacramento and the San Joaquin rivers. The waters of this region drain through Suisun Bay, through Carquinez Strait and into San Pablo Bay, the large and shallow bay at the northern extremity of San Francisco Bay. The South Bay is the local term for the large, mostly shallow part of the bay that reaches from San Francisco to the South and East. A less enclosed bay is the upper portion of Monterey Bay in the Pacific Ocean, visible at the bottom of the image.

This region is the home of the microprocessor, invented by Ted Huff at Intel in Santa Clara in 1971. The Santa Clara Valley ("Silicon Valley" or simply "The Valley" to locals) is the heavily developed region at the Southeast extremity of the South Bay. The first commercial microprocessor was the Intel 4004, which contained about 2300 transistors on a die ("chip") slightly larger than one inch square.

Although well known for silicon technology, the region is also the epicenter of the venture capital funding revolution that has powered business and technology breakthroughs in software, systems, biotechnology and most recently, the Internet. It is also a center of weapons technology. The Livermore Valley appears as a horizontal streak of development just East of the South Bay. Livermore is the home of the Lawrence Livermore National Laboratory, the nuclear weapons design center created as an alternative to Los Alamos in the 1950's with an initial mission focussing on the development of thermonuclear weapons. The nuclear weapons storage depot near Suisun Bay in Concord is said to host one of the highest concentrations of nuclear weapons in the world.

This image reveals an interesting juxtaposition. On the original image (provided on the Manifold CD) we can see beige and duff yellow colored regions on the edge of the bay near Silicon Valley. These are salt ponds where seawater is evaporated in the commercial production of salt. The same region where people invent and manufacture the most advanced technology ever conceived is also the place where one of the most ancient production processes continues to be practiced.
The Manifold System splash screens used for 5.xx and 6.xx series releases show the church of San Giorgio on the island of San Giorgio in Venice seen in a view across the Canale de San Marco from the campanile (bell tower) in St. Mark's plaza. The island of San Giorgio has been the site of a monastery since 982.

The patron saint of Venice is St. George. The church in his name was designed by Andrea Palladio and was begun in 1566. Other surviving buildings in Venice by Palladio include the Basilica, the Loggia Bernardo, the Palazzo Chiericati and the Villa Capra. To get to San Giorgio from St. Mark's square, take water taxis (vaporetti) 52 or 82.

The image is taken from a photograph shot the day after the total eclipse of the sun in central Europe on August 11, 1999, which was witnessed by the manifold.net team in commemoration of the official launch of Release 5.x development.

The August 11 eclipse path crossed most of Europe's most populated areas but was cursed with cloudy weather. Manifold 4.50 was used on laptops with GPS devices to find a location between Munich and Salzburg on the totality path that (given satellite weather photos) seemed likely to be in a break between clouds. Moving every few minutes from place to place on the autobahn to stay in a clear area, the Manifold team used the atomic-clock accuracy of GPS coupled with moving-map Manifold location to find a clear spot at the exact time of totality. A fabulously clear break showed the eclipse in full, cosmic glory. Within minutes, as everyone babbled over what they had just witnessed, the clouds closed in and the rain began. The team drove to Venice over the Brenner pass and the next day shot the splash screen photograph.

In the splash screen the island has been set in a landscape created with RasterLab, the Manifold internal raster algorithm development tool used to verify terrain window algorithms for Manifold System. RasterLab allowed development and verification of raster techniques while Release 5.00 was being created. The splash screen image was composed using over 40 layers, as seen in the Layers topic.

Troubleshooting

Most problems reported to Technical Support arise from user errors. Almost always the answer can be found in this user documentation or on the manifold.net web site. Frequently Asked Questions (FAQ) pages. The Troubleshooting part of this manual covers various elementary issues involved in installing and using Manifold System.

Fast troubleshooting:

- Make sure your system is correctly installed. See the Read Me First topic.
- Use the Contents tab in the Help system to see if your problem is covered in the Troubleshooting book topics.
- Use the Index tab in the Help system to find topics involved in your problem. Try different key words.
- Read the troubleshooting topics cited below.
- See the Technical Support topic for information on technical support and other free resources are available.

If any error messages appeared during installation your system is not completely installed. Track down the problem and eliminate it so that you can install the system without error messages before attempting to use it. The www.manifold.net web site will have detailed installation notes in the support pages to help resolve installation problems.

Very Important: Your system is not fully installed until you have installed any service pack that has been issued for Manifold System. Do not waste time attempting to troubleshoot a particular problem until you have checked the manifold.net web site and have downloaded and installed the latest service pack for Manifold System. Because we seek a perfect release, manifold.net tends to issue service packs more frequently than other vendors.

If you can reproduce a system lockup or crash using Manifold, please send a note to tech@manifold.net with step by step instructions on how to reproduce the problem. Reproducible system hangs or crashes go to the top of our engineering priorities for immediate repair. We have found this policy rapidly results in a virtually bulletproof release.

Temporary Files and the TEMP Folder

Manifold uses the TEMP folder defined in Windows to create temporary files. The precise location of the TEMP folder is shown in the Environment Variables dialog accessible from Control Panel - System - Advanced - Environment Variables (be sure to check both user variables and system variables and be sure to check both TEMP and TMP).

By default, TEMP points to

C:\Documents and Settings\User\Local Settings\Temp

where User is the name of the user. Temporary files created by Manifold are typically named bdhXXXXX.tmp where XXXXX is any combination of numbers and letters.

If your system crashes for any reason, such as a power failure, while using Manifold there may be one or more large temporary files left in the TEMP folder. These may safely be deleted if Manifold is not running.

Problems with Installation or Configuration

If you are reading this Help file, obviously enough of Manifold System has been installed so that Manifold can be launched and this Help file run. This simplifies troubleshooting.

Error Messages During Installation

- You must have Administrator privileges when installing. If using XP Home, you must login with the true Administrator account since some other accounts with "administrator" privileges do not have full administrator privileges.
- You must have a reasonably recent Microsoft Internet Explorer browser installed on the system.
- No other program should be running during installation. This includes any programs (except Microsoft Windows system processes) running in background that get launched automatically on startup. Disable all virus checkers, network snoopers, "value added" uninstall utilities and other programs.
- In Windows '98 and Me it is possible that a previously installed program broke your Windows dll's by replacing them with out-of-spec dlls or that the program failed to update your Windows dll's in the correct way. If you have installed a lot of shareware or programs from non-Windows vendors this might have happened. The fastest way to resolve this is to wipe the hard disk clean (reformat it completely) and then re-install Windows. Re-installing Windows without re-formatting the hard disk may not solve the problem since the re-installation may attempt to "preserve" out-of-spec dlls or registry entries. This is less of a problem with Windows 2000, XP or Server 2003.

Manifold won't launch. Menu items not available. Error messages on some menu choices. Can't execute scripts.

- Are you using a Runtime serial number? Runtime serial numbers do not allow interactive use of Manifold System.
- Were there any error messages of any kind during installation? If so, the installation is not complete and Manifold may not be fully functional. Resolve the installation difficulty.
- If the system was functional and is no longer functional in some way, has anyone installed new software that altered or deleted Windows system files on which Manifold relies?
- Has any user customized the system with add-ins or other customizations that remove menu items?
- Most toolbars are on by default and can be turned on/off via Tools - Customize. Best efforts have been made in this manual to show only default configurations; however, it is always possible that some illustrations show toolbars that must be enabled via Tools - Customize. Check to see if another user has not changed your configuration.
- Manifold menus and toolbars are context sensitive and will change depending on the type of component that is active. If a drawing window or layer is active, menus and toolbars will show commands and tools that apply to drawings. Image commands and tools will appear only when an image window or layer is active.

Toolbar settings or other options have changed unexpectedly.

- Has anyone else used your user account and changed the settings?
- Are you using a different Windows user account? All of Manifold installs as a shared application so that all user accounts may use the system. All option settings such as toolbar and window positions and any customization settings are personal to the user account that set them up. If you customize the system using one Windows user account and then login and launch the system using a different Windows user account you will not see the customized settings.

Transform toolbar is missing operators.

- Check which window or map layer has the focus. The transform toolbar will be loaded with operators that apply to the component type that is active. Click on the window or layer you want to work with and the toolbar will be configured with the operators that apply to that window. Operators for tables, images, and drawings are different because the data these components contain is different.
- Check the data type for the fields in your database. Remember that what appear to be numbers, like "3.56" can in fact be text string types and not numeric field types. You may think you have a table full of numeric fields when the table might have only string fields. In that case, the transform toolbar will offer only operators that may be applied to string fields and not to numeric fields.
No panes are visible. Project Pane has disappeared.

- Panes are not displayed until they are checked in the View - Panes menu.
- Toggle panes on/off with SHIFT-ALT-(letter) combinations. SHIFT-ALT-P turns the project pane one and off.

No scroll bars are visible.

- Manifold does not use scroll bars for images, drawings or maps. Hot scrolling using CTRL-right click is used instead because it is faster and uses less space. See the Windows topic.

Windows disappear when minimized

- If the project pane or other pane or window has disappeared after being minimized, check the vertical scroll bar on the right side of the main Manifold window. Windows can be positioned within Manifold so that they are partially out of the main window. In that case, a scroll bar appears. It could be that when the missing window was minimized it appears scrolled out of site in the main Manifold window.

Display windows refresh and then show blank contents

- In Tools - Options - Miscellaneous, check the Use GDI-compatible offscreen cache option. The problem is caused by a buggy video card driver (are you using an ATI card?) and this option uses a lower performance workaround that avoids triggering the bug.

Miscellaneous

- For normal operation you should have four times the maximum size of the files in use available in free disk space. If you are working with a 100 MB image you should have 300 MB free on disk. The extra space is needed to keep temporary versions of the image to allow Undo or abandoning of edits as well as to provide space for copy and paste operations.
- See the Memory Requirements topic for additional information on RAM and disk space requirements when working with larger projects.

Disk Space

- Always double-check you have enough free space on hard disk. If you have no free space on hard disk, Manifold will not be able to function because there will be no room for temporary files.
- Even if you have plenty of free disk space, check the location of the TEMP folder for Windows. If the TEMP folder is placed on a disk partition that does not have enough free space, Manifold will not be able to function correctly.
- If you work with linked images, clean out your cache files from time to time. Cache files persist forever and, in extreme cases, use up your free disk space unless they are manually deleted. See the recommended actions in the Managing Cache Files topic.
Problems when using Windows 95, 98 or Me

If you are using a Windows '95, Windows '98 or Windows Me operating system, before troubleshooting any problems with Manifold please read the Limitations topic. Specific problems covered in this topic include:

- Areas not always displayed in Windows '95.
- Zoom limitations in Windows '95.
- Crashes in Windows '95 and Windows '98.
- Printing limitations in Windows '95, '98 and Me

This topic has been placed here to catch anyone browsing the index and to redirect him or her to the Limitations topic.

See the Memory Requirements topic for additional information on RAM and disk space requirements when working with larger projects in Windows 95, 98 or Me operating systems.
Problems Importing or Exporting

Problems importing or exporting to different formats account for most Technical Support issues. Most such problems are caused by confusion arising from the limitations of legacy formats, especially when importing projected maps. The most confusing situation on import arises when a legacy format unsuited for the saving of projected data (such as .dxf or .shp) is used to save maps projected in an intrinsically user-unfriendly projection such as UTM.

On export, it is important to remember that legacy GIS systems such as ArcView and MapInfo are not able to handle all aspects of rich data that may exist within a Manifold project. Any export will inevitably involve manual intervention to simplify the data into those limited forms that the target system can handle. If you are exporting data for use within legacy systems it is your obligation to learn enough about the limitations of those systems to know how data must be dumbed down into something they can handle.

Importers do not work correctly or report errors.

- Are you sure you are using the correct importer? Several GIS formats use the same file extension but require different formats. For example, both NIMA NITF and UK Ordnance Survey NTF formats use a * .ntf extension for files. Files may be described casually and inaccurately as something other than what they are. The generic term “DEM” refers to at least five different formats, each of which requires a different importer.
- Is the file the format you think it is? Errors occur on web sites that provide files. The USGS web site, for example, has on occasion incorrectly provided FTP access to DEM files that were really SDTS DEM files and vice versa. Directories providing access to “DLG” files will often provide them in SDTS form.
- Is the file damaged? When working with a downloaded file, try downloading the file again in case an error was introduced during download. On rare occasion files will be damaged when loaded across a local network or when read from a damaged hard disk sector.
- Has the file been decompressed? Files are often published as compressed archives using “zip” or “GNUzip” or “tar” archival or compression methods. These must be decompressed or unzipped before use with Manifold importers.
- Has the file been correctly decompressed? When decompressing UNIX tar or tar.gz files with WinZip one must uncheck “TAR file smart CR/LF conversion” in the configuration settings to avoid introducing errors during the decompression process. Other decompression utilities may have similar nuances involved in correct operation.
- Do you have adequate free space on your hard disk and on the hard disk volume hosting your TEMP file? You should have free space that is three times the size of the imported file.
- Have you selected the right importer? Some GIS data files do not have extensions and so the right importer must be selected.
- When importing DLG files, are you sure they are in “optional” DLG format? This is the format imported by Manifold and has replaced the “original” format. DLG optional replaced the original DLG in government usage many years ago. However, on very rare occasions one may still encounter DLG files in “original” format.
- Files are sometimes provided without extensions when they should have extensions. For example, the 14 CD set of DLG files covering the US that was published by USGS in 1993 contains the DLGs in the form of zipped files. However, when unzipped, the result is files that are named using numbers without a three letter extension, for example SF4RDF04. These must be renamed to add a .opt extension to each file, for example SF4RDF04.opt.

Imported drawings appear to be incorrect.

- Is the imported data projected? Projected maps saved in old formats will require manual entry of the required projection formats. See Projections and Legacy Formats.
- Does the imported drawing represent a geographic drawing? If it is a CAD drawing it will require georegistration to appear in the correct location and scale.
- If importing a CAD drawing for non-geographic use and the scale is incorrect, read the topic for the importer being used to learn how to set scale when importing.
- Manifold importers use reasonable default settings for formats but individual drawings may require choices other than default settings depending on the specific nature of the file being imported. Read the Help topic for the importer being used, read any documentation that might accompany the file being imported and try again with different settings.
- If an imported projected geographic drawing does not match other drawings it may have been published using a different datum. Re-project it using the same datum as the drawings it is to match.
- Some drawings may be the victim of some fundamentally bad choice made by the publisher that irretrievably damaged their accuracy. Data on the edges of UTM zones in maps published in UTM
Troubleshooting

projection might suffer from this problem. Try to get the data in some other form, preferably unprojected.

- Some formats very poorly organize objects in drawing. Certain SDTS files, for example, can place large areas in the same drawing where they overlay and conceal smaller areas. Until the larger areas are deleted or moved to a different drawing the areas underneath might not be visible.

Imported drawings do not look like original maps.

- Are you sure you are comparing the same thing? GIS systems often have an option to save in different formats. The information saved by the exchange format you are using to import a map might not contain the same formatting information (colors, etc.) as that used by the GIS system to display a highly-formatted map.
- Formatting applied to the underlying objects drives the appearance of drawings or maps in the original system. This will be different from system to system. Not all exchange formats will convey formatting information in a way that’s usable by Manifold. See the Formatting topic for general information and the specific topic for the importer being used.
- If text or other embellishments do not appear it could be that the GIS system from which you are importing maintains such capabilities in a way that is not translatable into Manifold. See the Help topic for the importer being used.

Imported maps do not look like pretty road maps.

-Maps imported from most generic sources will require formatting. Read the Key Ideas topic and the Formatting topic.

Imported drawings or images seem empty, do not appear in maps, or appear in unexpected places.

- If the drawing or image does not appear in the map, use Zoom to Fit to make sure all of the data is in view. Select the image or drawing and GoTo the selection and zoom far, far in to make sure you don’t overlook anything. It could be that the item is visible in the map but is not in the location expected (and so is far away from the view seen in the window) or is so small (because it has not yet been scaled properly) that it is not obviously visible.
- Did you import from a geographically aware format? Import from non-geographic formats such as .dxf or .jpg will require georegistration to correctly locate the drawing or image.
- Did you import a projected drawing or image? If importing from a "dumb" format you may need to manually specify projection information. See the Projections topic.
- If the imported items appear in a tiny dot off the coast of Africa you have imported from a non-geographic format and must georegister the image or drawing or must manually specify projection information.
- Are you sure the drawing or image contains the data you think it does? Open the drawing or image within a drawing or image window to see how it looks in its native coordinates. For drawings that appear empty, use Zoom to Fit and change the formatting of points to a large size so that any points will not be overlooked. Drawings that you expected to contain lines and regions might contain only a few points that are so few and so small that the drawing appears empty. Open the drawing’s table to see if there are any records.
- If images appear empty it is possible (but very rare) that they are RGBA images with very high transparency set on each pixel. The pixels are there but are so transparent they cannot be seen. Check to see if the image is an RGBA image. If it is, click OFF the Alpha channel in the Layers pane so you can see the image without any transparency effects.

Problems importing or exporting to ESRI .shp "Shapefiles".

- Are you having trouble importing a shapefile that might contain projected data? A recent hack to the shapefile format incorporates projection information but most shapefiles that have been published predate this extension and so do not save projection information. If you use such shapefiles to import projected data you must manually add the required projection information. See the Projections and Legacy Formats topic.

Problems importing geocoded data from Excel.

- It’s not a good idea to keep databases or database-style lists of records in Excel because Excel does not have the built-in discipline to keep databases neatly organized that is provided by database
management programs such as Access. It's easy to go wrong in Excel by creating spreadsheets that are not really database tables, that co-mingle column headings and comments with record information, or that specify unexpected field types. The Manifold geocoded data importer cannot repair a confused data layout in Excel. The best approach to debugging a "database" stored in Excel is to first import it into Access. If you cannot import it into Access it is not a valid database table and Manifold will not be able to import it either. Organize the Excel file so it can be imported into Access. Better still, use Access in the first place.

Problems importing geocoded data.

- Is the problem reading latitude/longitude coordinates? Manifold reads all of the common ways of writing latitude and longitude values, but some data sets use such weird formats for latitudes and longitudes that the Manifold importers cannot be adjusted to read them. In such cases the latitude/longitude values must be translated into a standard form. We recommend standard decimal notation where each latitude or longitude consists of a whole degree value followed by a decimal point and decimal fractions of a degree: "38.0852". Latitudes from the Equator to the South pole are prefixed with a minus sign: "-39.0852", as are Longitudes from the Prime Meridian westward to -180 degrees longitude. It's possible to use Manifold to make conversions from really strange formats if you know how to use the transform toolbar. To make a conversion, import the database as a table and then use the transform toolbar operators to copy/translate the latitudes and longitudes into standard form. Token operators will be used, so learn how to use them. You can then export the table and then import it as a geocoded database to create a drawing showing the information it contains as points.

- Is the problem reading coordinates that are supposed to represent projected data? Read the Projections and Imported Components topic and the Projections book topics. Importing geocoded databases where the coordinates are for some projected coordinate system (such as UTM or Gauss Kruger) is expert-level stuff that involves a host of complications. You'll need to import the geocoded file as abstract coordinates and then manually set the coordinate properties to the exact projection and projection parameters that were used for that data.

- Did you try to import a list of addresses and failed? A database that has no location information other than addresses is not geocoded. To be a geocoded database, it must have a latitude and longitude field for each record that shows exactly where that address is located. Databases that do not have a latitude and longitude field for each record must first be geocoded so these field values are computed for each record.

- Did you expect to get a map and instead got a drawing full of points? Geocoded databases should be tables full of records that include latitude and longitude fields for each record. Importing such a geocoded database will create a drawing that contains points only. Each point is the location of one record.

- Did you try to import a geocoded database that you thought represented lines and areas coded as a series of records and failed? There is no GIS standard for representing lines or regions in the form of geocoded databases. You may have run across some data that purports to show map features in the form of ASCII lists of records or some other tabular format; however, if it is not one of the standard formats it cannot be read by Manifold. Use one of the formats supported by Manifold to import drawings that contain objects other than points.

Imported Tables have wrong field types or missing fields

- Different database formats save data using different approaches to field types. Some primitive format such as .txt or .csv don't save field type information at all. In such cases the importer must guess what data type should be used for that field. It is possible the importer will guess wrong. For example, it might import what you think is date time information as a text string. Use the Transform toolbar to copy/translate the data into the desired field types.

- When importing from complex formats such as SDTS a file may be imported as many different drawings. Some of them may have certain data fields while others do not. Look through all of the drawings created when looking for given data attributes. Also, some of the more complex formats (like SDTS) may require checking optional import boxes to map fields between tables and drawings.

Exported .mdb databases cannot be read by Access 97

Problems importing or exporting to .dbf format
• Have you made sure your Windows system is current as described in the installation instructions? Manifold uses Windows drivers to read and write .dbf files. If your Windows system has not been correctly updated to incorporate the latest Microsoft bug fixes and other current components you may not have proper Windows functioning in this important area.

• Some programs (especially those in UNIX) do not write .dbf files that are in accordance with Microsoft standards. The fastest way to resolve most problems is to make sure that all names (including file names, field names and so on) have no more than eight, plain alpha characters. See the Importing Tables topic.

Cannot write when exporting

• Are you sure you are writing to a directory for which you have write permissions? Your user account may not be authorized to write into that directory. Try writing to a different location.

• Are you trying to write onto a CD ROM? CDs are not writable. Try writing to a location on hard disk.

• Are you trying to overwrite a read-only file? If you copied a file from DVD ROM, in Windows that file will continue to be read-only even though you copied it onto the hard disk. The file had "read only" properties set when it was on DVD and copying a file in Windows copies all of the file's properties as well. You need to right-click on the file in Windows explorer and change the properties to make it writable.

• If you are trying to write into an external database you may not have correct permissions to write into that database. Check with your database administrator to see if the database is writable or if any special passwords or other access methods are required.

• Are you trying to write information that is not supported by the format? For example, a field name such as "My really long field name for Site $325" cannot be exported to ESRI .shp format due to the limitations on the number of character names allowed in field names in this format. Manifold's exporters will attempt to auto-truncate such names; however, a really determined user may find it possible to defeat such safety measures.

• Did you see any error messages during installation of Manifold? Manifold must install the latest versions of various Microsoft facilities for accessing data. These include ADO, Jet, DAO, ODBC and OLE DB files if your system does not currently have these standard Microsoft facilities for data access. If any other application is operating, some of these files may be locked and can not be updated. Make sure no background processes are running and re-install Manifold.

General inability to import tables

• Did you see any error messages during installation of Manifold? Manifold must install the latest versions of various Microsoft facilities for accessing data. These include ADO, Jet, DAO, ODBC and OLE DB files if your system does not currently have these standard Microsoft facilities for data access. If any other application is operating, some of these files may be locked and can not be updated. Make sure no background processes are running and re-install Manifold.

Terrain Windows are Blank

• Manifold requires a functioning OpenGL subsystem to display terrains. If there are no OpenGL capabilities in the system terrain windows will be blank when opened.

Miscellaneous

• For normal operation you should have four times the maximum size of the files in use available in free disk space. If you are working with a 100 MB image you should have 300 MB free on disk. The extra space is needed to keep temporary versions of the image to allow Undo or abandoning of edits as well as to provide space for copy and paste operations.

• See the Memory Requirements topic for additional information on RAM and disk space requirements when working with larger projects.
Problems with Commands or Tools

Manifold uses a context-sensitive, mode-oriented user interface for many command functions. Unexpected action of commands or tools is usually a result of having the focus being on a different window or being in a different command mode than was thought. Many Manifold commands and tools are designed to work within the selection or require a selection to be present; therefore, it is important to note whether a selection is present or not.

The first step in any troubleshooting is to check which window or layer has the focus. If a drawing window or layer is active the toolbars and menus will be configured for drawings. Image commands and tools will not be available unless an image window or layer is made active. See the Windows topic for information on what the “focus” means and what it means for a window to be active.

The second step in troubleshooting is to see what tool or command mode has been selected. If the Select Box button is pressed in the mouse will be in selection mode and cannot be used to zoom in or zoom out, for example.

The third step in troubleshooting is to see if there is any selection in the active component. Commands and tools will change their action to work within the selection, if one has been made. Some commands, such as Crop, work only upon the selection.

Unexpected command or tool action. Command or tool doesn't work.

- What is the active window or layer? Clicking back and forth between images and drawings will automatically switch the context of commands and toolbars to feature only those commands or tools that apply to the type of component at hand. Images and drawings are different types of components with different characteristics. Although some tools are similar and are usually directly analogous in both cases the precise action of tools will be different in drawings or images.
- What is the command mode the mouse is in? If you have chosen Zoom Box, the mouse will be in zoom box mode and not selection mode. Get in the habit of clicking out a tool button once you are done with that tool.
- Will the command or tool cause a visible difference? Some commands may not have any visually obvious effect. Perhaps the command worked correctly but had no visually obvious effect. For example, converting an RGB image to an RGBa image will not cause any difference in the appearance of the image.
- Does the command require a selection? Some commands such as a Cut or Crop work on the selection. If no selection has been made the command does nothing.
- Is the command affected by a selection? Commands such as transform toolbar operators will use autoscope, where they will apply to the entire component if there is no selection and will apply only to the selection if one has been made.
- Is there a selection? Most tools will work only within the selection. If you have made a selection and are trying to paint outside the selection there will be no effect. See the following paragraphs for cases where there might be a selection but it is not visible.
- When working with tables, check the field type. It's possible that what you think is a number is really a string field, for example. The specific action of commands and tools that work with tables will often depend on the type of the field involved.
- When working with images, check the settings in the tool properties pane and format toolbar. Painting with a size of 1 will have a greatly different effect than applying the same brush shape with a size of 20. Likewise, the Tolerance setting has a great effect on Touch Selection and the Bucket tool.
- Is the system busy executing a previous command? Check the System Activity indicator in the in the status bar at the lower right hand of the screen. When the system is busy it will show a 3D “bump”. If Manifold is busy it cannot execute a new command for you.

Objects created in Drawing in a Map do not appear.

If a map with several different drawings is open and you try to draw a new object in the drawing and it does not appear:

- Does the drawing being used have the same projection as the map? Right click on the layer tab for that drawing and choose Project to Map to force that drawing to use the same projection as the map.
- When creating drawings to be dragged into the map, make sure you click on the opened map first to activate it. While the map is active, click on File - Create - Drawing to create the drawing. If you open the map and click on something else (like, the project pane), the focus will move off the map window and the new drawing when it is created will not be created with the projection used by the map.
Troubleshooting

- Try **Zoom to Fit** to make sure all objects are visible.
- Does the drawing have 100% transparency set? This will make the drawing and anything in it total invisible because it is completely transparent.
- Is the drawing hidden from display? Double click on the layer tab to toggle it ON.
- If the objects are areas, is the drawing formatted so that the foreground color of areas is invisible color? If so, the areas will be invisible since this is a shorthand way in Manifold of turning off areas.

**Cannot change the format color of objects**

- In a map, have you clicked on the layer in which the objects are located?
- If you cannot change the color of red objects... are they selected? If so, they will be seen in red selection color no matter what their color is supposed to be.

**Items are not selected. Selection tools have no effect.**

- Is the selection visible? Check the **Selection Style** to make sure you have not turned off showing the selection. You might be making the selection OK and just cannot see it.
- In a map, have you clicked on the layer in which the objects are located?
- Is the selection very small or not in view? You might not realize there is a selection because it is only a few pixels in a large image and is not visible, or because the selected region is scrolled off screen. It might be off screen when making selections from table windows or via SQL or other non-mouse selection methods.
- Have you enabled selection for the types of objects you wish to select? If **Select Areas** has been enabled and **Select Lines** and **Select Points** have been disabled, any selection made with the mouse will apply to areas only. Making a mouse selection over lines or points will have no effect because they are not enabled for selection.
- Are you using a "closed" selection tool when an "open" tool is required? Default selection tools select objects that are entirely within the mouse selection zone. You may be trying to select a line, for example, that partially extends outside the selection zone drawn with the mouse cursor. Use **SHIFT** with the selection tool to get an "open" style of selection that will select all objects any part of which are within the zone drawn by the mouse.
- Maps will display the selection for all components/layers within them. It is possible to select areas in a drawing that is seen in a map layer above an image layer, where the selected area in the drawing appears to be a region of selected pixels in the image. This might occur in certain combinations of area styles and transparency effects for images and drawings. Click layers on and off to resolve any visual ambiguity.
- It is important to understand the different types of objects that appear in drawings. Trying to select the "inside" of a region in a drawing that is outlined by lines and is not an area object will have no effect because there is nothing there to select. See the Drawings topic for a discussion.

**Missing objects in drawings or missing regions in images**

- Have the objects or pixels been deleted?
- In drawings, have the objects been formatted to the same color as the background? Click off the **background** in the **Layers** pane.
- Missing points? Increase the point size so that small points are visible.
- Are the objects or pixels on screen? Click **Zoom to Fit** to make sure that everything within the drawing or image is within the window that's open.
- In drawings, are the objects smaller areas covered by larger areas? Click using **Touch Select** on any spot and see how many objects are selected. If two objects are selected where you think there is only one area there is another area under the area that you see. Select the smaller areas in a table window and move them to a different drawing. You can then organize them in layers in a map so they are above the larger areas.
- Missing regions in images might simply be regions of very high transparency in RGBA images.
- If you are running Windows '95, the operating system cannot display objects made up of more than 32,000 coordinates. See the Limitations topic. Switch to Windows 2000.
- If the objects are areas, is the drawing formatted so that the foreground color of areas is invisible color? If so, the areas will be invisible since this is a shorthand way in Manifold of turning off areas.

**No panes are visible.**
Panes are not displayed until they are checked on in the View - Panes menu or with a **SHIFT-ALT** (key) keyboard shortcut.

No scroll bars are visible.

- Manifold does not use scroll bars for images, drawings or maps. Hot scrolling using **CTRL-right click** is used instead because it is faster and uses less space. See the Windows topic.

Some toolbars are missing.

- The default installation of Manifold System contains the toolbars described in this documentation. If toolbars are missing or do not appear in the **Tools - Customize** dialog, check the **Config** folder within the Manifold System installation folder for an **XML** files that may have been added containing `<addin>` entries. An add-in may be used to add commands to Manifold and also to control the availability of toolbars.

Objects disappear when pasting into drawings.

- Were the objects selected? Manifold's Paste into drawings is a standard Windows Paste: if something is highlighted/selected when a paste occurs, that something gets deleted and is replaced with whatever is being pasted in from the clipboard. See the Using Cut, Copy and Paste in Drawings topic.

- Were the objects copied from a drawing that was not correctly georegistered? If you create or import a CAD drawing from a non-geographic format (such as DXF) the objects are created in Orthographic projection at the 0,0 intersection of the Prime Meridian and the Equator. If you then paste them into a correctly georegistered drawing (such as, for example, a drawing of city streets in some town in Europe or the US) the objects will not be seen in the drawing. They are in the drawing but they are still in a location somewhere off the coast of Africa at the 0,0 intersection. To remedy this, correctly georegister all drawings that will be used.

- If the objects are areas, is the drawing formatted so that the foreground color of areas is invisible color? If so, the areas will be invisible since this is a shorthand way in Manifold of turning off areas.

Compressed images don't appear in maps.

- A compressed image may or may not be displayed in a map, depending on the projection used for the image and the projection used for the map. If the projections are not the same, the compressed image will not appear in the map unless the projections are sufficiently similar to each other (not usually the case) so that the conversion between the two can be accomplished by applying an offset and altered scale.

Data attributes disappear or do not appear as expected after an operation.

- Many operations such as those in the Spatial Overlay dialog require correct setting of transfer rules for the fields that are to be transferred.

Strange Changes in object shapes when pasting into drawings
If we **Copy** selected objects like those at the left and **Paste** them into a different drawing and get the result at the right, the problem is that the drawing on the right uses Orthographic projection while the drawing at left uses Geographic Latitude Longitude projection. If a drawing is created when the project pane has the focus, by default it is created using the Orthographic projection. When the objects were pasted into the Orthographic drawing they appeared as they would be shown in that projection.

Situations like the above arise when we selected the objects in the lat-lon drawing, chose **Edit - Copy** and then clicked on the project pane and chose **File - Create - Drawing**. At the moment we clicked on the project pane we moved the focus to the project pane and so the new drawing was created in Orthographic projection. What we should have done was choose **File - Create - Drawing** while the lat-lon drawing was still the active window. In that case, the new drawing would have been created by default to match the drawing that was open and had the focus.

Note that the pasted North and South America objects are correctly seen in default Orthographic projection, which is, after all, a view from space centered on the intersection of the Equator and the Prime Meridian just off the coast of Africa. From that position North and South America appear greatly foreshortened as they are on the edge of the visible part of the Earth. The default Orthographic projection uses a "transparent globe" so that Alaska in the drawing at right is seen through the Earth. See the Projections topics for more information.

We can retrieve the situation by re-projecting the drawing on the right into Geographic Latitude Longitude projection.

**Problems printing. / **"No System Resources"** error when printing**

- Make sure you are using the latest version of Manifold and the latest Service Pack.
- What version of Windows are you using? Windows 98 and Me are full of bugs that often affect printing. Use Windows Server 2003, Windows XP or Windows 2000 to prevent bugs in Windows from interfering with print jobs.
- What printer resolution are you using? Try decreasing resolution and see if it helps. If you print in color, try black and white. If either of these steps helps, it is almost certain that the problem arises from a bug in the printer drivers supplied by your printer manufacturer. Download the latest version of your printer manufacturer's drivers to see if they remove the bug.
- How much RAM memory do you have installed in your system? 32 or 64 MB are not enough for serious printing jobs and 128 MB is only marginally OK. At least 256MB of RAM should be installed in the system.
- How much free space do you have on your hard disk? Print jobs can require lots of free space for temporary files.

**"Unknown Error" or "No System Resources" or "Can't Read Data Stream" errors when working with large images or other commands**

- 32-bit Windows editions are fragile when large processes are used. Switch to 64-bit Windows so that Windows errors do not interrupt work.
- Such errors are frequently caused by running out of free space on hard disk. Check the amount of free space on hard disk. If working with very large files and a system crash occurs (such as during a power failure) Manifold temporary files beginning with *bdh* may be found in the system TEMP folder and may be very large. These *bdh* temporary files may be safely delete after a crash to save space on disk.
- Errors may also be caused by limitations of the particular Windows configuration in use or by Windows bugs in Windows '95, '98, '98SE or Me. Check all items suggested for the Problems with Printing section above.
- Are you using Windows Server 2003, Windows XP or Windows 2000 with the latest Microsoft service packs installed? If not, the above messages are almost certainly caused by memory management or other bugs in older Windows releases.
- Make sure you have lots of free space on hard disk. Do you have a few gigabytes of free space on hard disk? If you don't have enough free space on disk to allow Manifold to create and use necessary temporary files the system cannot operate.
- Do you have a static Windows pagefile (where the minimum size is the same as the maximum size)? Has it been set to a very large size? If not, you could be running out of pagefile when Windows attempts to swap parts of a large job in and out of memory. Set up a large, static page file.
- Make sure your TEMP directory is on a hard disk that has lots (many gigabytes) of free space.
How much RAM do you have? Running with lots of RAM is a good way to avoid stepping on Windows bugs.

If some operations work OK and others do not, try saving the project to a .map file prior to the operation to move image data from memory to file mapping.

Keep in mind that images stored in compressed formats will expand to their real operational sizes when used in Manifold. Thus an image that takes only 200 MB in some compressed format could end up being a gigabyte in size when actually used. Make sure you have lots of free disk space to be able to work with such images.

Problems Saving or loading Projects

• Encountering errors of the form "Can't overwrite target file. The project is saved to [path] bdh17a.tmp"? This happens when you don't have enough space on the target disk drive or when the temp file or target file can not be read or written due to a locking error. Locking errors might occur because you have opened the temp file or the target file name in an editor, such as a hex editor, or have the target .map file name opened in another instance of Manifold. Rename the .tmp file given to a .map file to rescue the project that was saved under the .tmp file name.

• "Incorrect Data Check" errors indicate hardware problems, not Manifold problems, and usually arise from disk errors. This error message may occur seemingly at random as disk errors are encountered in an unpredictable way. Windows places information in scattered places on disk as free blocks become available when files (including temp files created or deleted by different programs or system processes) are created or deleted. Depending on the semi-random usage of blocks, a particular save or load may or may not involve a bad patch on disk. Note that disk is used in loading a project, because decompressing the project involves temp files created on disk. Likewise, saving a project to disk will involve not only the actual disk blocks used in the saved project but also disk blocks used for temp files created temporarily during the compression process. Regular use of Windows disk maintenance utilities can help avoid such problems; however, as systems age intermittent disk failures may indicate unreliable motherboard or disk circuitry and can be difficult to diagnose or eliminate.

• "[Can't overwrite target file ...]" errors usually indicate flaws in virus-checking software. The overwriting of the old file with the new file is done using a system routine, which gets called after Manifold closes both the old file and the new file. When a system routine is not able to overwrite the old file, some other process besides Manifold has locked it. This behavior is frequently experienced with virus scanners and other protection software. Trying to change the name in background won't work either: By the time you see the error message, the new file is already closed. In fact, it is closed even earlier, prior to the call that generates the error in the first place. Not being able to rename the file is yet another indication it has been locked by some other process besides Manifold. Important: Virus scanners and other protection software are frequently designed to inject a portion of their code into every running process. In this case, the behavior mentioned above can seem to be caused by the Manifold process, despite the fact that it is being caused by software external to Manifold that has been injected into the Manifold process.

If the geocoder does not work, check the following:

• Manifold Geocoding Tools extension product has been installed.
• All state files required are present (that is, required files have not been removed after installation).
• The Geocoding Database folder in the Tools - Options - File Locations correctly specifies the folder used to install the geocoding database. By default, this location is C:\Program Files\Manifold System\GCDB.
• If geocoding functions do not work within IMS, check that the geocoding database has been installed within the main Manifold installation folder, such as in the default path above.

If an address cannot be located in the geocoder, check the following:

• The address is correct. Nowhere is the ancient maxim of computing, "Garbage in, garbage out" more correct than in street address geocoding.
• The address does not contain secondary address information, such as "Apartment 20" co-mingled with the primary street address field.
• The address is a real street address and is not a virtual address, such as a Post Office box address (which, of course, can only be geocoded to a zip code).
• Try manually breaking up a single line address into street, city, state and zip fields. If the zip code cannot be found, check the zip code against the US Postal Service's website to make sure it is a valid zip code.

Miscellaneous
• For normal operation you should have **four times** the maximum size of the files in use available in free disk space. If you are working with a **100 MB** image you should have **400 MB** free on disk. The extra space is needed to keep temporary versions of the image to allow Undo or abandoning of edits as well as to provide space for copy and paste operations.

• See the Memory Requirements topic for additional information on RAM and disk space requirements when working with larger projects.

**General Advice**

Run 64-bit Windows using 64-bit Manifold. Doing so eliminates an entire class of 32-bit Windows bugs.
Problems with Tables

Most routine problems with tables arise from confusion over field types. The classic problem is working with a series of values like "3.145", "2.44" and so on and thinking they are numeric types when in fact they were imported from a database that stored them as text strings. Remember, in databases there is a difference between a numeric value that is 3.145 and a text value that has the ASCII characters "3", ".", "1", "4", and "5" arranged in a row. The numeric value is a number that can be multiplied, divided and so forth while the text string is just text characters that spell out something we read as a number, like the phrase "three point one four five."

General inability to import tables

- Did you see any error messages during installation of Manifold? Manifold must install the latest versions of various Microsoft facilities for accessing data. These include the latest MDAC as well as MDAC 2.5 if your system does not currently have these standard Microsoft facilities for data access. Make sure no background processes are running and re-install all required Windows updates as set forth in the Manifold installation instructions. If any errors occur during MDAC installation or other Windows updates, consult the Microsoft Knowledge Base to resolve the problem that is preventing your Windows system from being correctly updated.

Slow performance with SQL Server, Oracle or other OLE DB server

- When working with server-based OLE DB providers such as SQL Server and Oracle, users are strongly encouraged to maintain primary keys in all tables linked into the Manifold project. A side effect of how such servers interact through OLE DB is that if the table does not have a primary key, performance will be greatly reduced.
- If read-only access is acceptable, ADO.NET is often the fastest possible connection and should be used in preference to ODBC or OLE DB for that reason. Important: Tables linked from ADO.NET data sources are always read-only.

Trouble linking tables from an Oracle DBMS

- Always set the Allow saving password option. If this option is not set, the system will connect for the first time but not at all other times. The intricacies of the OLE DB / ODBC interaction that takes place within the Microsoft OLE DB Provider for ODBC Drivers are such that it is almost never possible for the Manifold to jump into the middle of the connection process and prompt the user for a username and password.
- Avoid using ODBC. Use the native Oracle (OCI) connection offered by Enterprise Edition. If you do not have Enterprise Edition and only need a read-only connection, use ADO.NET Oracle. If you do not have Enterprise Edition and require a read-write connection, or if you absolutely have to use ODBC, use either the native Oracle ODBC driver or a combination using the Microsoft OLE DB provider for ODBC with the Microsoft ODBC driver for Oracle, depending on what works best in your configuration. Many native Oracle ODBC drivers are limited to forward-only cursors, which is by far the simplest type of database cursor allowed in ODBC, and thus have limited functionality in Manifold.

I'm having problems with ODBC.

- General problems with ODBC: this is a standard Microsoft technology that is part of Windows. Get a good book on ODBC and Microsoft-stuff to learn more. Note that Manifold uses OLE DB to connect to ODBC. Avoid using ODBC if possible. Instead, use OLE DB.

Where do I find an ODBC driver for my database format?

- You don't need ODBC to open standard Microsoft database file types of the sort that can be opened directly with Access: dbase, FoxPro, Paradox, Excel, Lotus, text and .csv, and HTML tables. These can be opened directly using the correct selection in the Files of Type box within Manifold Open dialogs.
- If you don't already have them, the installation of MDAC 2.7 and 2.5 as set forth in the Manifold installation instructions will install ODBC drivers for the most popular database types (SQL Server and Oracle clients) as well as ODBC drivers that enable access via ODBC to the usual Microsoft file types. The ODBC drivers to the usual Microsoft file types are redundant, since these can be opened directly. If you neglected to update your Windows system with MDAC as required in the installation instructions, please repeat the installation, install MDAC and re-install Manifold.
Troubleshooting

- Most database management system vendors selling into Windows markets will provide an ODBC driver for their database as part of the product they deliver to you. Depending on the vendor, you may or may not be able to find a freeware ODBC driver for their format if you are not their customer.

- Use a good Internet search engine to search for web sites from which you can download ODBC drivers for the less common database systems/formats.

Problems connecting to external database tables. Tables not writable or visible.

- Do you have access permission to the machine hosting the database? When accessing tables over a network your user account must have correct access permissions. Note that a local machine user account is not the same as a user account of that same name in the applicable domain.

- Is the external database correctly configured? If you cannot see tables that you know are there or if you are unable to update tables this could be a result of the configuration options specified for that database by the database administrator. Oracle databases in particular have many configuration possibilities that may prevent you from writing to or even seeing certain tables.

- Are you using non-Microsoft middleware of any kind to connect to the database? Manifold is tested using standard Microsoft connection components. If you have replaced these with third party connection components, try running with the Microsoft component and see if the problem goes away.

- Are you using ADO .NET for the connection? Tables linked from ADO .NET data sources are always read-only.

Can't Undo table operations.

- The architecture of some external database providers makes Undo operations too costly for users. In such cases you will not be able to Undo changes made to the table. In theory, Manifold could support an Undo for any change in any table regardless of the underlying data provider; however, with the architecture used some providers such an operation would require constant backing up the entire table, with unacceptable impact on performance.

Missing fields in tables. Some fields are not visible.

- Check the View - Columns command to make sure that the fields have not been hidden from view.

- Importers may have option settings that allow you to import some fields but not others. Did you import the fields you now wish to see when the table or associated drawing was first imported?

- Importing from GIS formats uses the latitude/longitude coordinate information embedded in the GIS format to draw objects. GIS newbies often expect this embedded geometric information to also automatically appear in a database table associated with each drawing. That's not how it works. See the Editing Data in Tables topic.

- Importers may skip fields containing no data. This behavior is controlled by the Import empty columns in tables option in Tools - Options. By default, the option is off, which means that importers will only import fields that contain some data.

Values in fields are missing numbers or are the wrong numbers

- Check the field types. When copying floating-point numbers to integer fields the values will be rounded to whole integer values.

- Check the formatting specified for that field. If Manifold is told to show only two digits after the decimal point, that is all that will be visible.

- Are the Area (I) intrinsic values for area unusually low in a drawing’s table? If the drawing is in Latitude / Longitude these values are quoted in degrees. Project the drawing to see them in meters.

Tables are missing records.

- Check the View - Selection Filter settings for that table. The table could be set to filter out everything except the selection.

- Check all table options. If you have told Manifold to filter out empty records they will not be visible.

- Have you sorted the table by using View - Sort or by clicking on a column head? Check the position of the record pointer by noting the position of the scroll bar. It could be that the record you were looking at has been scrolled out of view as a result of the sort.

- Are you sure you opened the desired table?
MEMO fields from a FoxPro .dbf not imported correctly.

- One problem that arises from Manifold's use of auto-adaptive .dbf reading technology is that on occasion MEMO fields written by Microsoft's FoxPro application will not load correctly. A workaround is to use ODBC or OLE DB to connect to such files instead of the built-in .dbf importer. That is, instead of specifying a .dbf file in the Files of type box when importing a .dbf file or linking to it, we would specify an ODBC or OLE DB connection in the Files of type box and then use the ODBC or OLE DB dialogs to connect to that .dbf file.

- To connect to a FoxPro .dbf file we must first install an ODBC driver for FoxPro which is part of MDAC 2.5, available at:

- To read the file via OLE DB we must install an OLE DB provider for FoxPro, available at:

Unexpected results from table commands or transform operators. Commands have no effect.

- Is the operator affected by a selection? Commands such as transform toolbar operators will have a different effect depending on whether they are run on a selection or on all objects.
- Is there a selection? If you have made a selection and don't notice that there is a selection, the operator may be working but you won't see its effect because it is being applied to only those selected records that are not in view.
- Make sure the selection is visible. If a selection is present it will affect the action of many commands and operators. Check to make sure that Selection Style is enabled so that any selected records will be displayed with a red selection color background.
- When working with tables, check the field type. It's possible that what you think is a number is really a string field, for example. The specific action of commands and tools that work with tables will often depend on the type of the field involved.
- Are you sorting on a field and getting strange sort orders? If the field is not the type you expect the sort order may be strange. For example, sorting on a text string will result in lexicographic ordering that may be different than if the same values were represented using a numeric field type.
- Are you using View - Sort and getting strange results? Check the Use Whitespace and Use Case options.

Problems with selecting records.

- Is the selection style enabled? If None is chosen then even though the records are selected they will not be shown with a red background and you might not think they were selected.
- Select records by clicking on the record handle on the leftmost margin, not by clicking on the cells in the record. This allows editing within selected records without changing the selection.
- Select records using Replace, Add and the other selection modes to add to the selection or subtract from it or other wise modify the selection.
- Make sure selected records are in view. Records may be selected but are scrolled out of view in the table.
- When using ViewBots with Rank Columns: if the "wrong" records are being selected, check the argument you are using in the ViewBot to make sure it is a fractional value such as .85 or .90 to represent 85% or 90%. Rank Columns are percentages and so should be referred to by numbers that begin with a decimal point.

Problems pasting geocoded tables as drawings

- Are you sure the table contains latitude and longitude fields for each record? A table that does not contain latitude and longitude values is not geocoded and cannot be pasted as a drawing.
Troubleshooting

- Are the latitude and longitude values expressed as decimal degrees with negative numbers (minus signs) representing West longitudes and South latitudes? If this is not the case, use the Transform toolbar for tables to convert the latitude and longitude values into the required style.

- If the points pasted from the table appear in strange positions, are you trying to paste projected tables that are geocoded with projected coordinates as latitude and longitude values? The use of projected coordinates to geocode tables is an expert activity subject to many nuances. The geocoded coordinates in the table must be in the same projection system with the same projection parameters to paste correctly into a projected drawing. Try to find the same data set in a geocoded table that uses ordinary, unprojected latitude and longitude and paste that into a lat/lon drawing in the default way.

Problems running queries

- To edit a query, right click on it and choose **Edit**. Double clicking a query will also open it for editing.

- A query cannot be run unless it first has a SQL statement placed inside it with an **Edit**.

Apparent SQL bugs

- When running SQL within Manifold queries, one is using the Manifold SQL engine. When executing SQL within the Database Console one is using whatever SQL is the native SQL of the external database system. One should be aware that SQL implementations in various database systems can contain numerous bugs. For example, even as well crafted an SQL as Jet SQL used within Microsoft's Access products contains numerous bugs. If an SQL bug occurs within the Database Console, the bug should be tracked down with the vendor of the external database system being used.

- Most "bugs" reported in SQL are in fact syntactically incorrect SQL written by the user or other user errors. If you suspect a genuine SQL bug within SQL written in the Database Console, try importing the table and launching the same SQL query. If the problem does not go away, that's a sign of possible user error since it is unlikely that the same SQL bug would appear both within Manifold's SQL and in the SQL used by whatever database system was operated via the Database Console.

- If you suspect a bug within Manifold SQL and you have access to a third party SQL (such as SQL Server or Access), try exporting the tables involved and running the same query on the external system. If the problem continues, take a second look at the SQL for possible user errors.

- Do you have Internet Explorer 6 or greater installed? Manifold requires IE installation to make sure Windows is correctly updated with scripting components, including some that are necessary for correct operation of queries.

General problems with databases

- In a perfect world, every OLE DB provider installed on our systems would work without error. Regrettably, in real life the various database drivers and providers installed in our systems will contain numerous bugs. Even in the case of drivers provided by Microsoft, one only need read the Microsoft Knowledge Base and the release notes for various Microsoft service packs to see that vast numbers of bugs have been identified in such drivers. Manifold uses Microsoft drivers and OLE DB providers to connect to various types of database tables. If there are errors in the Microsoft drivers, such errors will affect Manifold as they would any other application.

- In sophisticated applications, if you suspect a database driver bug, take time to research the issue within the online Microsoft Knowledge Base. A useful experiment might be to import the table instead of linking to it and seeing if the problem persists. If it goes away, that is evidence that the problem lies in the external database system or is a bug in the drivers for that system.

- Access permissions are a never-ending source of possible difficulties. You must be familiar with Windows access permissions as well as any permissions scheme used by your DBMS to eliminate such difficulties.
Problems with Performance
See the Performance Tips topic for advice on improving system performance.

System appears to be locked up.

- Are you sure the system is busy? Check the System Activity indicator in the status bar at the lower right hand of the screen. When the system is busy it will show a 3D "bump". It could be that the system is not busy but has been put in a command mode, such as setting a control point, where the cursor will not be freed until the chosen command is taken to completion. Press the Esc key to exit a command mode. Check command button and status line to see if any commands are enabled.
- Does the system activity indicator show the system is busy? If Manifold is busy it cannot execute a new command for you. Some commands (such as sophisticated networking analytics) can take a very long time to accomplish. See the discussion in the Performance Tips topic about scaling up tasks very slowly to avoid unpleasant surprises.
- Is another application or Windows locked up? Try pressing CTRL-ALT-DEL (in 2003, XP, 2000 and ME) to see if this unlocks the console.
- Are you using Windows '98? These systems do not have the memory management sophistication of Windows Server 2003, Windows XP, Windows 2000 or Windows ME and will routinely lock up when significant amounts of memory are used. Switch to a modern Windows edition.
- For normal operation you should have four times the maximum size of the files in use available in free disk space. If you are working with a 100 MB image you should have 300 MB free on disk. The extra space is needed to keep temporary versions of the image to allow Undo or abandoning of edits as well as to provide space for copy and paste operations.

If you can reproduce a system lockup or crash using Manifold, please send a note to tech@manifold.net with step by step instructions on how to reproduce the problem. Reproducible system hangs or crashes go to the top of our engineering priorities for immediate repair.

Unknown Errors
Manifold cannot work correctly if your machine does not have adequate RAM, an operating system that can handle the necessary RAM, or adequate disk space.

- Are you using large images? Many image formats are compressed. When imported, the images they contain will expand to require considerably more RAM than indicated by the size of the file on disk.
- Are you using Windows XP or 2000? If not and you are working with larger projects you have probably encountered a bug in Windows, not in Manifold.
- Do you have enough free space on disk? Larger projects should have gigabytes free on disk.
- Is your page file large enough? Allow 2.5 gigabytes per running instance of Manifold.
- Are you running other applications at the same time as Manifold? Other applications could be using up RAM that is needed for Manifold.
- See the Performance Tips topic for additional information.
- See the Memory Requirements topic for important information on RAM and hard disk memory requirements.

Disk Space

- Always double-check you have enough free space on hard disk. If you have no free space on hard disk, Manifold will not be able to function because there will be no room for temporary files.
- Even if you have plenty of free disk space, check the location of the TEMP folder for Windows. If the TEMP folder is placed on a disk partition that does not have enough free space, Manifold will not be able to function correctly.
- If you work with linked images, clean out your cache files from time to time. Cache files persist forever and, in extreme cases, use up your free disk space unless they are manually deleted. See the recommended actions in the Managing Cache Files topic.

Important Configuration Notice
**Very Important:** Before starting Manifold, go to the Windows Control Panel Display dialog Effects tab and make sure that the *Show window contents while dragging* check box is **not** checked.

- In Windows XP this option is found in the Control Panel's *Appearances and Themes - Display* choice under the *Appearance* tab by pressing the *Effects* button.
- In Windows XP or Windows 2003, from the Start button open the Control panel and then open the *Display* dialog. Click on the *Appearances* tab and then press the *Effects* button. Uncheck the *Show window contents while dragging* check box.
- In Windows 2000, Windows ME and Windows 98 open the Control panel and then open the *Display* dialog. Click on the *Effects* tab, and uncheck the *Show window contents while dragging* check box.
- In Windows Vista, open the Control Panel and click *Appearance and Personalization*. Click *Customize colors*, then click *Open classic appearance properties for more color options* and click the *Effects* button. Uncheck the *Show window contents while dragging* check box.

Checking this box will greatly slow down the system when displaying complex maps and images because it forces a refresh of the window contents with each minor change in mouse position while dragging the window. Make sure the box is **unchecked**.
Problems with Projections

There is no way to troubleshoot problems with projections that does not require fairly sophisticated understanding of what projections are all about. Read the Projections topics before beginning any troubleshooting. Don't skip anything since problems with projections almost always involve a battle with obscure details.

I want to combine several maps into one and the data won't line up. Objects in drawings using the same projection do not align well.

- Are you trying to combine maps using different UTM zones into one UTM zone map? That won't work due to limitations of UTM. See the Universal Transverse Mercator (UTM) topic. Get the data in unprojected form and use a different projection for a combined map.
- The same problem occurs with projected maps in Gauss Kruger, State Plane Coordinate System and many other projection systems. These are systems of projections that are designed to allow mapping of limited, local regions within a fixed system of local projections. They are unsuited for combining data from different geographic regions.
- Is the data accurate to begin with? If the drawings come from different sources it might not be a projection problem but just a matter of differing accuracy in maps from different sources.
- Are the datums the same? Using exactly the same projection parameters but different datums will result in slightly different positions that will make a difference in high accuracy applications.
- Did the data originate in unprojected maps or did you import it from projected maps? If imported from projected maps, it could be that the projection parameters you supplied are not the correct ones intended for use with this data. See Projections and Legacy Formats for discussion of the potential problems. Note that publishers of data in projected form will sometimes specify the wrong information for use with their files. The wrong datum is often a problem.
- Did you use the Edit - Assign Projection dialog in an attempt to set projections? That's a specialized dialog that should be used only to correct an error during import from a format that does not save projection info. Use the Edit - Change Projection dialog to re-project a drawing, image, surface or labels component.
- If projected data is imported from an older package, did the software used to create the imported files use the same projection standards as Manifold? Manifold uses high accuracy projection formulae and definitions to USGS standards. There is no guarantee that a legacy package uses the same definitions and high accuracy formulae. Avoid this by using only unprojected data from older packages.

Drawings, images or surfaces disappear from a map after projection.

- Did you use the Edit - Assign Projection dialog in an attempt to change projections? That's a specialized dialog that should be used only to specify the correct projection after importing from a format that does not save projection info. Use the Edit - Change Projection dialog to re-project a drawing, image, surface or labels component.
- Was the component imported from a format that does not save projection information? Formats like .dxf and .shp for drawings and .jpg or .gif in images do not save projection information. The component may look visually correct after import, but if it is not imported with the correct projection and georegistration any subsequent re-projection will cause chaos. After importing from a geographically-unaware format you'll have to manually specify the projection by using the Edit - Assign Projection dialog. See Projections and Legacy Formats.

Using a projection causes extreme distortion.

- Did you choose the right projection for your intended usage and region? Some projections cause intense distortion. Not all projections are usable for all types of data. See Projecting a Map.
- Did you specify reasonable projection parameters for your data set and intended usage? Specifying the wrong center latitude and longitude for a projection, for example, can cause even a well-chosen projection to show a highly distorted view.
- If you specified projection parameters manually after importing a projected drawing from a "dumb" format, it could be that the wrong projection parameters were provided for use with that data or that you made an error when entering the parameters. Check the projection properties to make sure they were entered correctly.
- Was the component imported from a format that does not save projection information? Formats like .dxf and .shp for drawings and .jpg or .gif in images do not save projection information. The component may look visually correct after import, but if it is not imported with the correct projection and georegistration any subsequent re-projection will cause chaos. After importing from a geographically-unaware format you'll have to manually specify the projection by using the Edit - Assign Projection dialog. See Projections and Legacy Formats.
Troubleshooting

- If you attempt to change a projection by changing the Edit - Assign Projection dialog you are not changing the projection but rather are changing Manifold's interpretation of the existing coordinate values. Change the projection using Edit - Change Projection to permanently change the projection for drawings, images, surfaces and labels. Use Edit - Assign Projection to change the projection used by a map.

**Objects drawn in maps change shape or position unexpectedly after projection.**

- Are large objects involved? When drawing an object in any geographic drawing it is important to use Segmentization to prepare the object for possible re-projection.
- Is the center of the projection (for projections that have specifiable centers) reasonably near the object? Many projections will greatly distort objects that are not near the center.
- Have you chosen a sensible projection given the location of the object? For example, using a "whole world" pseudocylindrical projection to show a single island near the Arctic circle is a poor choice if you wish to avoid distortion.
- When using the Orthographic projection, have you checked the Clip Coordinates box? If not, the entire world is "wrapped" around the projection and objects from the "opposite" side of the world will be seen co-mingled with objects from the "front" side of the world.

**Changing a projection is not permanent**

- Changing a projection in a map with Edit - Assign Projection only changes the projection used by that particular map. It won't change the native projection of components used as layers in the map. If you later open one of those components in its own window or in a different map window the projection will not have been changed. To permanently change the projection of a component used in a map, use the Project to Map choice in the layer tab context menu to re-project it to the map's projection or open the component in its own window and use Edit - Change Projection to specify any projection desired.

**Re-projecting an image or other large component causes error messages**

Manifold cannot work correctly if your machine does not have adequate RAM, an operating system that can handle the necessary RAM, or adequate disk space.

- Are you using large images? Many image formats are compressed. When imported, the images they contain will expand to require considerably more RAM than indicated by the size of the file on disk.
- Are you using Windows XP or 2000? If not and you are working with larger projects you have probably encountered a bug in Windows, not in Manifold.
- Do you have enough free space on disk? Larger projects should have gigabytes free on disk.
- Is your page file large enough? Allow 2.5 gigabytes per running instance of Manifold.
- Are you running other applications at the same time as Manifold? Other applications could be using up RAM that is needed for Manifold.
- See the Performance Tips topic for additional information.
Problems with the Internet Map Server

See the Map Server Overview for general information on Manifold IMS (Internet Map Server). This topic covers some of the same points in slightly different ways since often one of these points has been overlooked.

Read through this entire topic at least once, then print it out in hard copy and go through it line by line, checking each line off with a pen or pencil as you investigate. Take nothing for granted and assume nothing. For example, don't assume permissions are correctly set. Actually check each and every file and folder involved for the right permissions on the IUSR_ or NETWORK SERVICE or ASPNET account, as the case may be.

Getting Ready

Running Manifold IMS has to do mostly with elementary operation of Windows as well as Microsoft's Internet Information Server (IIS) or whatever HTTP server is being used. Running Manifold IMS itself is very simple.

Of course, IMS can't run on a web server machine if Manifold has not been installed and activated on that machine.

In all cases of debugging, login using the Administrator account on the machine being used as a web server. Use the actual, local Administrator account (which may need to be enabled for usage in Vista) and not just some account that you are sure has Administrator privileges, whether it be a local account or a domain account. Use the actual, local Administrator account.

Tech tip: Users (especially in Vista) who are convinced the account they are using has "adequate administrative privileges" should be the first to login using the actual, local Administrator account.

To run a web site you need basic Windows administration skills. You must understand what is mean by a login and what is meant by permissions and how to check and set permissions. Any good book on Windows administration will explain this. If you do not know what permissions are and how to check and set them, you will not be able to identify and eliminate the most common user errors that prevent IMS web sites from running.

Verify Manifold installation

The first step in case of trouble is to verify that Manifold has been installed and activated on the web server machine. This is easy to do. Gain physical access to the web server machine and login using the Administrator account. Stop IIS. Reboot the machine. Verify IIS is still stopped. Now, launch Manifold interactively. Does Manifold come up without any activation dialog? If yes, you have Manifold installed and activated on the web server machine. Check the Help - About dialog and verify that you are not running Personal Edition (Personal Edition does not have IMS). While you have the Help - About dialog open, write down the exact build number in use, the Manifold edition in use and any extensions that are installed. Exit Manifold. Restart IIS.

If you have installed a Manifold edition other than a Runtime license and you cannot launch Manifold interactively, then you have not correctly installed Manifold and Manifold IMS will not work.

Note that the above verification is not possible if you have installed Manifold using a Manifold Runtime license. Runtime licenses cannot be launched interactively. The lack of an ability to launch Manifold interactively for debugging purposes is one reason that runtime licenses are not recommended for IMS beginners.

Verify installation of accessories

Some web sites may involve accessory software, either Manifold extensions or software provided by third parties. Check to make sure any such software has been installed. The most common errors:

- Verify presence of required Manifold extensions. If your web site utilizes features from Business Tools, Geocoding Tools or Surface Tools make sure these have been installed and activated. You can verify this in the Help - About dialog that was opened in the above paragraphs.
- Verify presence of image server modules, if used. Many web sites use Image Servers to fetch background images. Make sure that the web server machine has the required modules installed (usually placed in the Manifold installation folder). It is a very common error to create a project on some development machine using image server modules and then to forget to install the required image server .dll files on the web server machine as well.
Troubleshooting

- Verify presence of other required software. If your web application uses other software, such as DBMS packages or other software, make sure the required applications have been installed. For example, if you have created a web page using Excel web queries as shown in the A Flashy Demo - Web Queries and KML example topic, you will need to have Microsoft Excel installed on the web server.

Verify web server operation

The next step in case of trouble is to verify that your machine is capable of operating as a web server and that you know how to create and operate simple web pages on that machine. This is not something to be taken for granted, especially if other people have had access to your web server machine, as it is possible that some person or security update has altered IIS or other Windows settings in a way that prevents basic web server functions from operating as you expect.

Before debugging any problems with Manifold IMS, please create a simple web site not using Manifold IMS on your web server and browse it from a different machine. If you cannot create a web site on your web server that does not use Manifold IMS, then most likely the problem (or, at least one of the problems) has nothing to do with Manifold IMS. Get your web server running first with a simple web site.

For example, if you are running Windows Server 2003 you might discover that no web site using .asp pages can run.

Important: For enhanced security, Microsoft's Windows Server 2003 product comes with Internet Information Server configured so that .asp pages are not enabled. .asp pages must be turned on within IIS for Manifold IMS to function correctly.

When running Manifold IMS in 64-bit Windows editions, use of 32-bit ASP / ASP .NET must be enabled. See the discussion in the Creating a Web Site topic.

Create a Simple HTML Page

In your web page publication folder, create a file called hello.html that contains the following text:

```html
<html>
<body>
<p>Hello, world!</p>
</body>
</html>
```

Can you view this file as a web page from your local machine? Can you view this web page from your intranet or Internet as you would like to see your IMS site? If you cannot view this file, do not proceed any further with IMS until you can figure out how to create, publish and view this simple web page.

Create a Simple ASP Page

Once you know you can create and view a simple HTML file you know that your web server is operational. The next step is to verify that it can handle ASP by creating and viewing a simple .asp file.

If you are creating IMS pages using VBScript, create a file called hellovb.asp that contains the following text:

```html
<html>
<body>
<% response.write("Hello, world!") %>
</body>
</html>
```
If you are creating IMS pages using JavaScript, create a file called `hellojs.asp` that contains the following text:

```html
<%@ language="javascript"%>
<html>
<body>
  <% Response.Write("Hello, world!") %>
</body>
</html>
```

Can you view the `.asp` file as a web page from your local machine? Can you view this web page from your intranet or Internet as you would like to see your IMS site? If you cannot view this file, do not proceed any further with IMS until you can figure out how to create, publish and view this simple `.asp` web page.

Create a Simple ASP .NET Page

ASP .NET is not enabled by default in recent versions of IIS. To verify ASP .NET is up and running create a file called `test.aspx` in your root web server directory and paste the following into it:

```html
<html>
<body>
  <h1>The date is <%= Response.Write(DateTime.Now.ToLongDateString()) %></h1>
</body>
</html>
```

Visit `test.aspx` with a browser and if you see a sentence giving the current system date ASP .NET is working.

[This example was contributed by user mlinth on the Georeference forum, and comes from the book *Beginning ASP.NET 3.5 in VB 2008: From Novice to Professional, Second Edition* by Matthew MacDonald.]

Next Steps

The Manifold side of troubleshooting consists mainly of checking that Manifold is correctly installed, is available to all users, and that the files needed to be used are where the `config.txt` file says they are. Check the following:

- Has Manifold Professional Edition or higher been installed on the web server machine? Note that Manifold Personal Edition does not include IMS.
- When Manifold was installed on the web server machine, did you login as Administrator to do the installation? Note that Vista may require the Administrator account to be enabled before you can use it.
- When Manifold was installed, was it installed for use by all users?
- If it is more than 30 days since the serial number was issued, has Manifold been permanently installed using an Activation key on the web server machine?
- When Manifold was activated, did you login as Administrator when entering the Activation key?
- Are you attempting to run Manifold simultaneously in interactive mode and as the IMS map server at the same time? Execute an `iisreset` when changing from interactive use of Manifold to IMS use or vice versa.
- Have you copied all the files created by the Export Web Page dialog to the correct folder within the `Inetpub\wwwroot` folder hierarchy on the web server machine?
- Has the `.map` file being used been placed at the location specified for it in the `config.txt` file?
Troubleshooting

- If you are using ASP, does the system's IUSR_ user login have permission to execute Manifold.exe in the Manifold System installation folder? Check this using Windows Explorer to view the security settings on the file.
- If you are using ASP, does the system's IUSR_ user login have permission to read the .map file in use? Check this using Windows Explorer to view the security settings on the file.
- If you are using ASP, does the system's IUSR_ user login have permission to read and write the system's TEMP folder? Check this using Windows Explorer to view the security settings on the file.
- If you are using ASP, does the system's IUSR_ user login have permission to read and write all folders and files used in the application, such as temp folders for linked images, .mdb or other files used in linked tables, or database access for components linked from databases?
- When working with Windows Server 2003, have .asp files been enabled in IIS?
- When working with Windows Server 2003, does the NETWORK SERVICE account have all the permissions enumerated for the IUSR_ account above?
- When working with Windows XP x64, does the NETWORK SERVICE account have all the permissions enumerated for the IUSR_ account above?
- If you are using ASP .NET, does the ASPNET account have all the permissions enumerated for the IUSR_ account above?
- If you are working in a 64-bit Windows edition, have you installed a 32-bit version of the .NET framework as well as the 64-bit .NET framework?

The number one problem with IMS reported to tech support is that users neglect to add the IUSR_ account with access permissions to security settings for the .map file in use. A related error is that after checking permissions are correct users edit the .map file with Manifold and, without realizing it, change permissions so that the IUSR_ account no longer has access permissions to the .map file. Saving a .map file with Manifold will preserve file permissions on Windows 2000 and later systems, but this is always something worth checking.

To check permissions, using Windows Explorer (do not just depend on the IIS management console or other server management console), right click on the .map file, choose Properties and verify in the Security tab that the IUSR_ account for the system has necessary read and execute permissions.

Very important: In 32-bit and 64-bit versions Windows Server 2003 and in 64-bit Windows XP the account used for Internet visitors is not the IUSR_ account as with earlier Windows versions. Instead, the NETWORK SERVICE account is used. When ASP .NET is employed the ASPNET account is used.

Windows Server 2003 and 64-bit Windows XP operators should understand the NETWORK SERVICE account is meant in all cases where this documentation discusses the IUSR_ account.

Web pages operating in an ASP.NET environment may require different permission settings than those operating in an ASP environment. For example, the default login used by ASP.NET is ASP.NET, while the default login used by ASP is either the IUSR_ account or the NETWORK SERVICE account. When running in ASP .NET, the .map file and all other data being accessed from the ASP.NET environment must be readable by the ASPNET user account.

ASP .NET operators should understand the ASPNET account is meant in all cases where this documentation discusses the IUSR_ account.

While there is no end of trouble that can arise from willful misconfiguration of Microsoft Internet Information Server when attempting clever tricks, in the case of simple web sites problems arise most frequently from a handful of common errors:

- Can you create and browse a simple web page not involving Manifold IMS on the web server machine? If you have not correctly configured or installed Microsoft IIS on the web server machine so that you can create simple web pages without using IMS, then you will not be able to serve web pages involving Manifold IMS either.
- Attempting to run a web site with Manifold IMS at the same time Manifold is running interactively on the same system. Do not run Manifold interactively at the same time you are trying to run IMS. To make sure Manifold is not being run interactively, reboot the web server machine after running Manifold interactively.
- Failure to arrange required read and execute privileges for the IUSR_ account (or, the NETWORK SERVICE account or ASP.NET account if applicable). The IUSR_ account must be able to access the .map project as well as any tables required for linked tables or linked drawings and it must be able to execute Manifold System. The IUSR_ account must also have read and write privileges in the system TEMP folder as well as execute privileges for the Manifold.exe executable. In case of trouble, always check the permissions on the .map file. Use Windows Explorer to check all permissions: don't rely
on the IIS management console to check permissions. If any linked components appear in the project, the IUSR_ account must have read privileges to work with those files as well. For example, if an .mdb file is used to generate a linked drawing the IUSR_ account must have read and write permissions for that folder so that the lock file for the .mdb file can be created. When checking permissions, open Internet Explorer, right click on the file or folder, choose Properties and then check the settings in the Security tab. Don't assume that the web administration dialogs used by IIS will set these permissions for you. If using image servers, the IUSR_ account must have read and write privileges in the folder used to cache the image server files.

- If you have opened the .map file in Manifold System, check the permissions again. They might have been resent to not include the IUSR_ account. Saving a .map file with Manifold will preserve file permissions on Windows 2000 and later systems, but this is always something worth checking.
- Failing to install Manifold System on the web server machine for use by all users (a checkbox in one of the Manifold System installation dialogs).
- Neglecting to maintain links correctly when working with a project that uses linked tables, linked drawings or Enterprise Edition components.
- Attempting to use Enterprise Edition features, such as shared components, on a web server machine that is not licensed for Enterprise Edition.
- Failure to install the Geocoding Tools extension as well as the geocoding database within the Manifold System installation folder when using queries that include geocoding functions (or failure to have MapPoint installed if it is being used as an alternative geocoder).
- Failure to install or activate (using an Activation key) features contained in the Business Tools, Geocoding Tools or Surface Tools extensions if these features are used by the IMS application.
- Neglecting to place the .map file where the config.txt file says it is supposed to be.

**Manifold or the map server won’t launch**

- To run the map server and serve web pages, no interactive session with Manifold can be running on the same machine.
- To work with Manifold interactively, no map server session can be running on the same machine.
- Do an iisreset command in the Windows Command Prompt window before attempting to work with Manifold interactively after the map server has been active.
- Make sure to save the .map file after creating it or making any alterations interactively in Manifold. The .map file must be saved before the map server can use it. After editing a .map file, make sure by using Windows Explorer to view Security settings that the IUSR_ account (or, the NETWORK SERVICE account if applicable) still has read permissions on the .map file.
- Have you provided a serial number and Activation key? When Manifold is running as a map server it will not raise the Activation dialog. Before attempting to use the map server within Manifold you must launch Manifold interactively at least once to provide a serial number for preliminary installation, or a serial number and Activation key for permanent installation. See the Activation Keys and Serial Numbers topic. If you provided just a serial number without an activation key and it has been more than 30 days since the serial number was issued, you will have to launch Manifold System interactively so you can provide a serial number and an Activation key for permanent installation.
- When installing Manifold, did you install Manifold System for everyone to use on the computer? This is the default choice in the installation dialogs.
- When you installed Manifold System, did you login as Administrator to perform the install? If you activated Manifold System using a serial number and Activation key, did you login as Administrator to do so? It is a common error to think that using an account which supposedly has "Administrator" rights is an OK substitute for using the actual Administrator account. Avoid unpleasant surprises by using the actual, local Administrator account.
- Check access permissions on the .map file as noted below.
- When using a .map project using Enterprise Edition features, the web server must have Manifold System Enterprise Edition installed.

**Permissions**

- Note that in Windows Server 2003 or 64-bit XP the account used for Internet visitors is not the IUSR_ account as with earlier Windows versions. Instead, the NETWORK SERVICE account is used. Likewise, when running ASP .NET the account used is ASPNET.
- The .map file used with the web site must have security permissions such that the IUSR_ account (or, the NETWORK SERVICE account or ASPNET account if applicable) used for Internet browsers has read access. Manifold must be installed for everyone to use on the machine. If any linked drawings or linked tables are used in the project that is published, the IUSR_ account must have all necessary privileges required to work with the tables that control those linked drawings or linked tables. Note: the
Troubleshooting

"IUSR_*" account is named using the computer name of the web server machine. If the web server machine is named "GODZILLA" this account will be called "IUSR_GODZILLA".

- When using linked images in an IMS web application it is important that the web application has read and write permissions in the cache folder, or otherwise it will not be able to use the tiles cached for the linked image.

General problems browsing the web site

- Confirm IIS is operational by launching Internet Explorer and browsing http://localhost ...If this does not work, IIS is not functioning. You must have IIS functioning correctly before attempting to work with Manifold IMS within IIS.
- Verify the directory to which the Manifold IMS project is published is within the publication directory structure of IIS. Create a small test.html file and then browse to it using http://localhost.pathname/test.html where "pathname" is the directory path to the directory in which you are placing your Manifold IMS files.
- Check to make sure Manifold is not running on the system interactively. Manifold IMS cannot function on a machine where an interactive Manifold session is running. Close all Manifold sessions, reboot and try the browser again.
- Make sure no interactive Manifold sessions running on different machines are trying to use, across a local network, the .map file from which the Manifold IMS site was published. Manifold IMS needs to use that .map file during operation and no other process should use that .map file.
- If a newer version or service pack of Manifold has been installed, or if you have worked with Manifold interactively on the web server machine, reboot the system to make sure there are no older processes lingering.
- After changing either the .map file in use or any of the .asp files or accessory files in the Manifold IMS site, do an issreset in the Windows Command Prompt window to unload all objects involved so that the new versions are guaranteed to be in use.

Browser compatibility

- Client browsers must be at least "4.x" vintage IE, Netscape, Mozilla or Opera browsers when the "Compatible" template is used to generate a site.
- The Info button is not available in sites generated using the "Compatible" template.
- Client browsers must be at least "5.x" vintage IE, Netscape, Mozilla or Opera browsers when the "Standard" templates are used to generate a site.

Configuration problems

- When developing a Manifold web site on one machine and then installing the site and .map file on a different machine that is used as a server, make sure that the server machine is correctly updated with the correct .map file.
- Make sure the server machine has the latest version of Microsoft Internet Explorer installed (at least IE 6 is required).
- Make sure the server machine is running Windows Internet Information Server 5.0 or more recent.
- Check that the server machine has the same version of Manifold installed together with the most recent service pack (if any have been issued) as the development machine. For example, if your development machine uses Manifold 8 and the web server is still running Manifold 7x, the web server machine won't be able to open the Release 8 version .map file.

Queries don’t work as expected

- Stop IIS in Internet Services Manager. Execute an issreset in a Windows command prompt window. Launch Manifold interactively on the server machine and see if the query works correctly.
- Check the component that is published (it will be listed in the config.txt file in the IMS web site files). Does the query in any way refer to a component outside that which is published?
- Is the query a SELECT query? Only SELECT queries are allowed.
- Does the query generate more than 200 records for the table? Only the first 200 records will be published to the web page.
- Does the query use features available only through extensions? If so, has the requisite extension been installed?
A site that worked before no longer works

- Check to make sure that IIS is running.
- If IIS is running and the browser shows an error message citing a particular .asp file and a line number, check to make sure there is not an interactive session of Manifold running on the server.
- Make sure Manifold has not been removed (de-installed) from the web server.
- Using Windows Explorer check permissions for IUSR_ on all files and folders involved. Note that re-editing a .map file can change permissions on that file.
- Check to make sure that the Manifold installation has not been damaged (e.g., the Manifold directory in the installation has accidentally had files deleted, etc.)
- Perform disk maintenance to make sure disk errors or other problems have not damaged the Manifold installation.
- Verify there is adequate disk space for all temporary files created by Manifold IMS.
- Reboot the system to fix any Windows instability.
- Did you activate your copy of Manifold? It could be more than 30 days since your serial number was issued and an Activation key is now required as well as a serial number.
- Make sure no interactive sessions of Manifold are running on the web server.

If geocoding functions do not work within IMS check the following:

- Manifold Geocoding Tools extension has been installed.
- The Geocoding Database has been installed into the GCDB folder within the main Manifold installation folder. By default, this location is C:\Program Files\Manifold System\GCDB.
- All state files required for the geocoding database are present (that is, required files have not been removed after installation).
- If MapPoint is to be used as an alternative geocoding data source, has MapPoint been correctly installed? Note from the main IMS topics that MapPoint requires special permissions settings.

More performance is needed

- Read and think carefully about every line of the Performance Tips topic.
- Read and think carefully about every line of the Optimizing Performance topic.
- Eliminate any unused fields in the components being published.
- Eliminate any unused components in the project being published.
- Make a backup copy first, and then simplify the drawings used by increasing the size of the View - Properties - Precision parameter and then running Normalize Topology. Most drawings used in web applications can be reduced in size/complexity by a factor of ten without any objectionable visual effects. This will dramatically speed up the site.
- Don’t use images when drawings will do.
- If you must use images, use linked images that are compressed images or linked images served from an Oracle Spatial server or other DBMS server.
- Make sure that all components appearing in a map have the same native projection, which should be the same as the map’s projection.
- Use a smaller size window in the IMS site. Users may be complaining because you are sending very large images to them that take time to download through a slow Internet link.
- Use x64 Windows and x64 Manifold.
- Add RAM memory to the system. RAM is cheap. Install gigabytes of it. Install enough so the entire .map file plus all of your Windows processes can be in RAM.
- Use large, fast hard disks spinning at 7200 RPM or faster.
- Use SATA interfaces on your disks and configure a striped RAID array.
- Specify a static (predefined size) Windows page file that is far larger than ever will be necessary. This is faster than a dynamically re-sized page file.
- Use multiple hard disks. If you have two disk drives keep the system TEMP directory on a different disk drive than the web site. Ideally, if you have four disk drives the system TEMP directory, the system page file, the .map file and IIS and the web site will all be on different disk drives. This allows the disk drive heads to seek independently from each other as each of these four different files is used. This is
Troubleshooting

less of a factor if you have so much RAM that the page file or the .map files do not require any disk accesses.

- Use faster processors or use multiple, multicore processors.

Problems with ASP .NET

- Did you choose an ASP .NET version of the templates in the Export Web Page dialog?
- ASP .NET allows use of dependent DLLs, which if the system is misconfigured will lead to error messages such as "A dynamic link library(DLL) initialization routine failed." The most likely reason one or more DLLs are not getting initialized when loaded in an ASP.NET environment is that the system can not locate the dependent DLL modules to which it is linked. To work around this, include the path to the Manifold installation folder into the system PATH variable. That is, go to Control Panel - System - Advanced - Environment Variables and append the path for the Manifold installation folder (typically, C:\Program Files\Manifold System) to the system (not user!) PATH variable. Then restart IIS, or, better yet, reboot the machine. This should get rid of the problem.

- Web pages operating in an ASP.NET environment may require different permission settings than those operating in an ASP environment. For example, the default login used by ASP.NET is ASPNET, while the default login used by ASP is IUSR_xxx, where xxx is the machine name. The .map file and all other data being accessed from the ASP.NET environment must be readable by the ASPNET user account. Use Windows Explorer to check the security settings for all files involved in your web site to make sure that ASPNET can read them or execute them (in the case of executables such as manifold.exe). See the analogous discussion for the IUSR_ account.

Technical Support

Most Manifold System users find that the Help documentation, web pages, training aids and participation in Internet forums amply serve their needs for understanding and support. For those users who want direct technical support by manifold.net staff, technical support products are offered for sale by manifold.net, including options for email technical support as well as voice telephone support.

License fees paid for Manifold System do not normally include technical support. Although manifold.net may provide technical support (including Service Packs or some limited number of support incidents, typically two per license) at no charge on a voluntary basis, the voluntary provision of technical support is not a commitment by manifold.net to continue to provide technical support free of charge. Normally, any free incidents that are provided as part of a license are standard tech support incidents that cover installation and interactive features only. Standard support incidents do not cover developer level features such as scripting, programming, customization, IMS, Enterprise Edition features, SQL and any question involving Runtime licenses.

To learn about technical support products or services (either paid or free) that might currently be available for Manifold System, please visit the Support page at www.manifold.net - this page will always be updated with the latest technical support information for Manifold System. Information and procedures published in the Support page on the website supersede this topic.

Regardless of how you acquired your Manifold System license or what technical support arrangements you have made, the Manifold team always appreciates receiving direct email with bug reports, comments, or suggestions for product enhancements. For tips on making suggestions that will rapidly influence the product design process, please see the Contacting manifold.net topic. To avoid spending a support incident, make sure that any such suggestions or reports clearly indicate that you do not want a reply.

Very Important: Please do not send any proprietary information or suggestions in which you or any one else claim any intellectual property interest. Please only send information or suggestions that are in the public domain.

Free Support Resources

The fastest way to get technical support is to not need it in the first place. The following resources are free to all users:

- Search this documentation thoroughly before trying alternative routes to support. Most requests for technical support are answered with a one-line email citing the relevant topic in this documentation.
- Read the Troubleshooting topics.
- Check the Support page at www.manifold.net to see if any routine updates for Manifold System have been released. If so, download and install the latest update. Updates add new features and repair bugs. New features will often remove limitations or otherwise make the system easier to use.
- Visit pages at the manifold.net website that give examples of customization (.xml files, for example), scripting within Manifold, programming in third party applications, web site creation and so on.
- At the www.manifold.net website, visit the Support page to consult the Support FAQ and other free resources.
- Participate in the Manifold System user community online forum at the GeoReference forum, especially if you are engaged in scripting or other advanced uses of Manifold. See the Help - Manifold on the Web topic for fast access to the Manifold online community and other resources. See the Support page on the Manifold web site for links to other online user communities.
- As always, Internet links can change overnight. If you can't find the above forums or links, see the Support page for current information.

Note that posting a question to an online user community such as the GeoReference forum is not the same as communicating directly with manifold.net technical support or sales personnel. If you wish to report a bug, make a suggestion or request technical support, contact manifold.net directly.

Do Not Waste Support Incidents

With the exception of initial installation and activation questions, any question sent to technical support or any question of a technical nature, however trivial, sent to other manifold.net addresses will cost an incident.
While it is entirely up to the user what questions he or she wishes to ask of technical support, the advice of the tech support staff is to avoid wasting technical support incidents on utterly trivial questions that are easily found in the documentation or other free resources. Most questions sent to technical support are elementary questions already answered in Help, the Support page or other manifold.net web pages or on free Internet resources such as the GeoReference forum. The wise user will avoid wasting support incidents on easily-found information.

See the Help - Manifold on the Web topic for fast access to the Manifold online community and other resources.

**All Support Questions are Routed to Tech Support**

Tech support incidents also apply to all questions of a technical support nature that are sent to sales or to any other manifold.net email address. (Some users occasionally try to gain additional incidents by sending email of a technical support nature to sales. Such emails are forwarded to tech support.) This policy applies to all questions, no matter how trivial or sophisticated. Do not waste support incidents by sending simple technical questions to sales or other manifold.net email addresses. Instead, take a moment to search and read Help.

Some manifold.net staffers participate in various Internet forums. All such participation is voluntary and is done on the employee's own time, not on company time. If you obtain the email address of a manifold.net employee, please do not use that address to send questions of a technical support nature to that employee. All such questions will be routed to tech support and a tech support incident will be required. This policy is intended to protect the individual privacy of manifold.net employees and to preserve the ability of staffers to participate in public forums without risking abuse from unfairly directed tech support questions.

**Using Support Incidents / Tokens**

If you have received some limited number of support incidents as part of your purchase, visit the Support page at the web site to learn how to request technical support.

Tech support can only be obtained by using technical support tokens. A token is like a serial number, a sequence of letters and numbers that uniquely identifies the rights to one technical support incident. Tokens are available for standard support incidents and for developer support incidents. Tech support inquiries (regardless of which manifold.net email address they are sent to) unaccompanied by an unused technical support token will not receive technical support.

There are two ways to get technical support tokens:

- You may receive some number, usually two, free tokens as part of acquiring a Manifold license.
- You may purchase technical support tokens. Purchasing a technical support project provides you with tech support tokens of the number and class you have purchased.

**Keep your tokens confidential.** Whoever has possession of a valid token can use it for tech support. If someone else obtains a support token from you they can use it to get support and thereafter that token will be used up - you will not be able to use it.

To use a support token, write to tech@manifold.net with the token included in the first few lines of your email. Include that token in any further email exchanges related to that incident. For example, if tech support asks any questions that require a reply from you, include the token in your reply. A convenient way to do so is to simply include the body of previous email exchanges in the text body of your reply.

**Do not use attachments or HTML email.** Any attachments will be stripped out for security reasons, and HTML email will be converted to text email.

**General Guidelines for Contacting manifold.net**

**Very important:** When emailing manifold.net, to avoid having your email deleted by anti-spam software, do not attach any files, cc any third party, or send emails that have blank subject lines, blank "from" fields or almost blank subject lines such as "Re: " with no other subject text. We suggest using a subject line that clearly identifies your email as a matter that involves manifold.net or Manifold System.

Do not use obscenities or words commonly found in spam, such as references to drugs or other off-topic matters. This will avoid having your email deleted by automatic spam filters.
Other Guidelines

When interacting with manifold.net, please observe the following:

- Please include all of your comments within the email. Do not attach .doc, .pdf or other files containing text. Do not send images unless requested.
- Please do not attach any files to emails sent to tech support. If a sample file is requested, tech Support will provide upload instructions to upload the files by FTP.
- Do not contact technical support unless your system is up to date with the latest Manifold edition, the latest Manifold update, all current Windows service packs and other Microsoft updates.
- Please respond promptly to tech support emails. Incidents inactive or involving tech support questions that are left unanswered for seven days will be closed. Re-opening the matter later will cost another incident.
- Please answer all questions asked by tech support. If you do not answer all questions the incident will terminate. Re-opening the matter later will cost another incident.
- Keep in mind that there are many engineers at manifold.net, so the person who replies to some subsequent exchange in a thread might not be the same person with whom you initially corresponded. That's why it is a good idea to preserve the entire thread within any reply you make.

Please follow the above guidelines to avoid wasting tech support incidents. Tech support can help you rapidly if you provide full information and promptly answer all questions.

Runtime Licenses

Runtime licenses are provided with no bundled support incidents. Any questions involving a Runtime license require a developer support incident. If you plan on using a Runtime license and deploying it to a different user, plan on providing any support that user requires.

Keep Up To Date

Do not contact technical support unless you have:

- Installed the latest release of Manifold and the latest update for that Manifold release.
- Assured your computer system fulfills all hardware and software requirements set forth in the Requirements web page for your edition of Manifold.
- Installed the latest Windows service pack for your version of Windows.
- Installed the latest Jet 4 service pack.
- Installed IE 6.0 or greater.
- Installed the latest drivers for your video card and printer if these are involved.

Manifold uses many Microsoft system resources. If there is a bug in Microsoft code, it could cause problems within Manifold. Microsoft has a continuous program of identifying and fixing any bugs in Windows or other Microsoft components through service packs. In addition, Manifold service packs will fix bugs that are discovered within Manifold.

Therefore, a condition of using tech support (to avoid wasting tech support resources on problems that have already been fixed) is that you must have the latest Manifold release and update installed. You must also have the latest Microsoft service packs for your version of Windows, for IE and for Jet 4 installed. You must have IE 6.0 or greater installed as well.

Tech Support Offered Only for Current Release

Tech support is available only for the most recent release and the most recent update of Manifold System. If a new release of Manifold System is announced make sure to upgrade to the new release if you would like to use technical support incidents. An important part of every update and new release is the correction of bugs found in previous releases. Having the most recent release and update of Manifold installed avoids any time wasted on the consideration of bugs that have long been fixed. It also avoids confusion raised by old methods that have been superseded by newer and better ways of operating Manifold.
Whenever a new release of Manifold System is announced, licensees of the previous release have traditionally been offered an upgrade for a nominal fee for a limited time (usually 45 days after publication of a new release). After that, the fee for upgrading could be considerably higher so don't miss the opportunity to upgrade to the new release when it comes out.

It is especially important to upgrade to a new release if you have procured technical support products such as a ten-incident support product. Any unused tokens from the previous release of Manifold will be wasted if you do not upgrade to the most recent release. It makes most sense to take advantage of the initial, nominal cost, upgrade offer when it comes out.

If you actively use Manifold, by default Manifold itself will notify you when a new update (including new release) has been published. If you are not actively using Manifold, make sure to check into the manifold.net web site from time to time for news of new updates and new releases.

Do Not CC Third Parties

When writing to tech support, do not "cc" third parties. Manifold.net tech support does not respond to emails that are shared with third parties or are cc'd to any other recipient, including postings on newsgroups. There are three reasons for this policy.

- The first reason is financial: A tech support incident is a valuable service provided to a single individual. It is not offered to multiple individuals at the same time.
- The second reason is practical: Experience shows that users will puff up their expertise and are less willing to admit dumb actions when an exchange takes place in front of third parties. To avoid any incentive not to be completely honest all tech support exchanges must occur in private.
- The third reason is privacy: Tech support may at times need to discuss information that is covered by the Manifold privacy policy. Because the policy allows no disclosure to any third party we require all such communications to occur in private. Even if users waive their privacy rights we are not willing to waive our privacy policy. Only if it is never violated can we absolutely guarantee the privacy policy.

Support questions that are cc'd to third parties may end up wasting any tokens used.

Contacting Technical Support using a Token

Tokens are long alphanumeric strings that are sent to you when you purchase technical support incidents, like the following:

63AD4E38E989-4490B540-7DF13F3D3ACDCF56EA6CC8896CC9

If your email viewing program uses a narrow window, when you read the email that sends you your tech support tokens you may see the a token as "wrapped" to appear on more than one line. There are no paragraph breaks or "end of line" characters in a tech support token: it all consists of letters and numbers on a single line.

When using a technical support token, provide it exactly as sent to you. Do not change upper case to lower case, add or delete any numbers or letters or hyphens. Do not change it in any way. To avoid confusion between digits such as zero and the letter "O", it is wise to use Copy and Paste to copy the tech support token from the email in which it was sent and then to paste it into the email you are writing to tech support.

If you have a valid, unused tech support token you may contact manifold.net technical support by sending an email to tech@manifold.net - You must include a valid, unused technical support token in the first few lines of your email message. The example below shows the beginning of an email letter to tech support that begins with a token on the first line and then continues with the letter:

63AD4E38E989-4490B540-7DF13F3D3ACDCF56EA6CC8896CC9

Dear Tech Support,
I am using 8 pro (8.1.0.1834) on WinXP Pro SP3 running on a Dell Latitude 1300 laptop with a Core 2 Duo, 2GB of RAM, 60GB of disk with 25GB free
space. When I open a map window that contains a drawing layer (it can be any
drawing, like the example Mexico drawing on the download site) and then
choose File - Export - Drawing the only choices I see in the Save as type box
in the Export Drawing dialog are DXF files or KML / KMZ files. How do I
export to shapefiles?

Technical support and the email "bots that automatically scan all emails to tech support know a token when they
see one, so there is no need to add descriptive text such as "I'd like to use the following token" or other
comments. Simply placing your valid, unused technical support token in the first few lines of the email message
is enough.

Include the token in any subsequent emails in that thread. This is easily done if you get in the habit of including
all previous exchanges in the body of any response.

If you ask a question that requires a developer support token (any questions on programming, scripting, SQL,
Enterprise Edition, web serving, any customization of any kind) you must provide a developer level support token.
A free token for standard technical support will not suffice.

If you do not have a technical support token, you cannot use manifold.net tech support. If you send an email to
technical support without including a valid, unused technical support token in the first few lines of the email
message, you receive a form letter reply indicating the need for tech support tokens. If you use a token that has
already been used up, you will receive a form letter stating the token you used has already been used up.

If you send an email asking questions of a technical nature to any other manifold.net email address it will be
routed to technical support. Folks who repeatedly write with technical questions to other manifold.net email
addresses (such as sales) will have whatever tokens they have available used up, and could end up being barred
from manifold.net email systems.

Information Required when Contacting Tech Support

Any request for technical support must include, at a minimum, the information technical support may need to
service the request. Such information must include:

- A valid, unused technical support token.
- The specific manifold.net product you are using with build number from the Help - About dialog.
- The exact Windows version in use and the Windows service pack applied.
- The exact version and name of any Windows emulator, virtual machine or any other operating system
  modification, if in use.
- The brand of personal computer you are using (or motherboard).
- The processor you are using.
- The amount of RAM installed in your system.
- The total amount of disk space installed in your system and the total amount of free disk space.
- A description of the problem.
- A description of the data set or map you were using.
- Very Important: If you can do so, provide a specific sequence of actions that reproduce the problem
  using only maps or data sets from the Manifold CD.
Submitting a request for tech support without the above information will delay assistance until the required information can be obtained. See the example above.

**Tech tip:** The answer in the above example is to open the drawing in its own window to be able to export to the full list of formats to which drawings may be exported. Alternately, right click on the drawing in the project pane and choose Export. Maps have layers, so when opening a map window and choosing File - Export the map can only be exported to those drawing formats available for export that work with multiple layers, such as DXF or KML / KMZ.

### Checking Status of Tech Support Tokens and Serial Numbers

To check the status of any particular technical support token or Manifold serial number, visit the Support page on the www.manifold.net web site to find a link to the Serial Number Status page. The status page may be used to find out if a particular technical support token has already been used.

The status page also may be used to find out if a particular serial number is a 32-bit or 64-bit serial number, whether it is still active or has been revoked (as might occur if it has been traded in for an upgrade), what product it authorizes and how many Activation keys are available.

**A reminder:** Any use of a serial number or technical support token, such as checking status via the Serial Number Status page, should be done using Copy and Paste from the original serial number email sent out by manifold.net.

When checking the status of Manifold serial numbers, do not use the "masked" version of the serial number that may be displayed in the Help - About dialog which ends in a series of X characters. The masked version displayed in Help - About has had the final characters altered with a series of X characters so that someone who has physical access to your computer cannot steal your Manifold serial number. The masked version displays enough of the serial number so you can determine for your internal record keeping which serial number you used on a particular machine, but not enough of the serial number for someone to be able to steal it and use it to obtain Activation keys or other wise use it.

### Bug Reports

User reports are a key aspect of identifying, tracking down, and annihilating bugs. The most important requirement for this process is the ability to reproduce a reported bug in the lab. Therefore, we ask that any bug reports (if at all possible) include a specific sequence of steps that will reproduce the bug when applied to a data set that is provided on the Manifold download site. Please make sure you have installed the latest Service Pack and have verified the bug still exists before submitting a bug report.

Bug reports are **not** considered incidents if you do not request a reply. If you wish to report a bug, send an email of any length; however, make it clear you do not require a reply. For example, begin your letter with "Bug report - no reply necessary."

Users will at times send in a bug report and then ask that the bug report be confirmed or denied as a known bug. This is counted as a tech support incident because the user is asking for a custom report of bug status. Most bug reports (well over 95%) do not identify a new bug. Instead, they are errors arising from failure to read the documentation, the FAQ, the Knowledge Base or otherwise are errors of concept or operation. True bugs are very rare.

When a bug report is received it goes into a queue for examination. If it is found upon investigation to be a real bug it gets fixed and eventually appears as a bug fix in an update. Publication of the update is notification of the bug. Updates are published so frequently that it is faster to simply eliminate a bug than to note it on a web page. If you want a custom response as to whether what you think is a bug really is or is not a bug, that requires usage of a tech support incident.

If you do submit a bug report and do not request a reply, Tech Support may contact you as part of their investigation. If so, that does not count as an incident. See the manifold.net web site’s Support pages for additional information on bug reports.

### Updates

Corrections of errata are made through Updates (formerly called Service Packs), which may be downloaded by authorized users from Manifold web sites. Manifold releases from 7x onward will by default advise you when
launched if a new update is available. The latest update automatically includes all fixes and upgrades issued in previous updates.

**How to Avoid Needing Technical Support**

The good news is that answers to most technical support incidents are really simply answers, so simple that users are often embarrassed by how obvious the answer was. That's OK, as it is human nature to sometimes overlook the obvious. The key with technical software like Manifold is to leverage the strong part of human nature, the ability to understand and apply cool new things, by having and applying an adult expectation of the effort required to master those cool new things. That means carefully reading documentation and taking advantage of the many resources on the web and in literature for self-education.

If you read documentation and instructions carefully you will eliminate the need to use technical support in most situations. A very high percentage, over 95%, of tech support incidents are used to ask questions for which the answers may be very easily found in the documentation or installation instructions for Manifold.

An astonishingly high percentage, perhaps 30%, of support incidents involve a letter from a user such as "I have read the ... topic but I don't see the answer to this question" even though the topic includes an obvious answer to that question. Why this happens has been researched, as people usually do not want to waste their time writing to tech support if they have the answer immediately at hand.

Initial results indicate that when some people are in a hurry to find the answer to an important question they speed up their review of documentation to the point that they no longer actually read it. Instead, they skim it quickly. If they are in a big hurry they might skim documentation so quickly they miss even glaringly obvious answers, such as those highlighted with bright red, boldfaced "Important" markers.

The solution to this is to slow down, take your time and read the documentation carefully. If you find yourself uncontrollably skimming documentation and unable to actually read it, try reading out loud. This will force you to slow down and actually read each word.

This is especially important if you are attempting a complex project under a lot of time pressure and have encountered difficulties. When people rush through debugging they are never sure whether or not in their haste they have really checked some possibility, so they go back and check it again and again. This is a terrible waste of time. It's like a person who has lost his or her car keys and in great haste starts going through the pockets of clothing they have worn recently. Some people get into a panic and find themselves going through the same pockets over and over "to be sure."

A better method is not to panic. Slow down. Debug what you are doing systematically. Write down a list of possibilities and check each one carefully and systematically. Consult the documentation on each point and read each relevant topic slowly and very carefully, thinking about what that topic teaches and how it may relate to the task at hand. Keep careful notes on what you have done and the settings you used for various dialogs so that if you ever do decide to contact technical support you can provide an exactly accurate and detailed description of what you have done. Quite often, just the act of writing a detailed account of what you have done will reveal an error.

**Tech Tips**

**Invest in Education** - People who invest in their own education by reading the documentation, discussing issues with other Manifold users in the online community and investing into education via training products or coursework in schools will almost never require technical support. If your time is valuable (whose time is not valuable?) it is worth your while to invest into your own education through training.

Many third parties provide training for Manifold System. The training products sold at [http://www.gisadvisor.com](http://www.gisadvisor.com) have been especially praised by Manifold users in online forums. Many users report that self-paced training products like those sold by GISadvisor.com are an easier path to learning than relying exclusively upon reading documentation.

**Bugs are Very Rare** - Newbies will at times leap to the conclusion that the problem they are experiencing is caused by a bug in Manifold. Anecdotal evidence indicates that the less carefully someone has read the documentation, the more likely they are to leap to such a conclusion. This is almost always a mistake, as bugs in Manifold are very rare and are almost never found by inexperienced users.

It is usually a waste of time and energy to think that whatever problem you are experiencing is caused by a bug in Manifold. That is almost always a psychological drain that will divert your attention from successfully
understanding what is going on. Instead, focus your energy on a detailed understanding of what you would like to do and the Help topics that are relevant. The possibility of a bug is always kept in mind by tech support, but leave it up to tech support to determine if a bug is the source of the problem. This even tech support cannot determine without lots of detailed information so careful attention to what you are doing is necessary in any case.

It's true that just as "even a broken clock is accurate twice a day" on very rare occasion there are new bugs found as a matter of happenstance by beginners. Don't let that rare statistic distract you from starting your analysis by assuming you have missed something in the documentation.

You can, of course, submit a bug report following the guidelines in this topic even if you are not sure that something is a bug or not. Manifold gratefully receives thousands of bug reports knowing full well that almost all of them are not bugs. But all are gratefully received so that even if only one small bug is found by sifting through many reports the system will become better than it is. Collecting and acting upon many bug reports is one reason the system has become so clean that new bugs are very rare, and that's the way everyone wants to keep it. Just don't allow the writing of a bug report to distract you from the more likely possibility of a nuance missed or misunderstood.

In a related note, beginners uncertain of their skills will sometimes panic after reading Internet forum threads discussing "bugs" in Manifold. Almost all "bugs" discussed in Internet forums on Manifold are not bugs. There are a few, of course, that experts discuss; however, most postings that include the word "bug" in the subject line do not discuss bugs but rather end up being a discussion of something the original poster did not understand.

This is such a common effect that the use of the word "bug" in a subject line tends to indicate the poster is either a rank beginner or is easily panicked, as Manifold experts know that new bugs are very rare and whatever problem they are experiencing most likely derives from some fine point that is yet to be learned or has been missed. So they don't normally post using that word in the subject line. Instead, they post using a subject line that describes unidentified behavior as narrowly and neutrally as possible. The last thing an expert wants is to be embarrassed by calling something a "bug" only to learn that it was a simple error on his or her part, so experts tend to avoid that word.

In contrast, beginners will at times launch a thread on some awful "bug" they have discovered when they have simply neglected to learn and apply the software properly. On occasion some people persist in insisting something is a bug even after numerous experts have responded to their post pointing out the problem is not a bug. But still the thread persists using the word "bug" in the subject and that can scare other beginners as yet uncertain of their own mastery of the software. Don't let that bug you!

FAQ

See the Support page on the manifold.net web site for frequently asked questions, Knowledge Base articles discussing what is or is not a tech support incident and other useful information about using technical support.

Why do you charge an incident for even simple questions? There is no way to foretell if a particular email received from a user is a trivial question or a sophisticated question. Each question requires reading by a trained engineer to assure that a sophisticated question that might appear to be a simple question to the untrained eye is properly answered.

For that reason, it costs as much to process an apparently trivial question as it does a carefully thought-out, complex question. In fact, some classes of trivial questions require more effort because users neglect to provide required information or because through lack of experience the user might think something is far simpler than it really is.

Ultimately, since questions must be processed by talented engineers what an incident really covers is the time spent by that engineer together with associated support costs. It doesn't matter if someone is using up that engineer's time with a brilliant question, or if that engineer's time is used up suggesting the customer read a web page, like the Support page, for material that is explicitly discussed on that page.

Why do you ask for so much information? Long experience shows that having all required information at hand is the fastest way of resolving a tech support problem. If Tech Support must repeatedly ask that necessary information be provided, a technical support incident will be charged. For example, tech support questions of the form "I can't open the file - what am I doing wrong?" are a good way to waste incidents. Tech Support must respond by first asking for all information noted as set forth in the Support page on the manifold.net website. Only after that information is provided can Tech Support help the user.
Most tech support questions are very elementary errors or misconceptions. Even the smartest people can miss something very simple, so it is essential in Tech Support that the details be nailed down. Getting the background information is essential to getting the details right.

Some users will not cooperate with Technical Support. The classic case is a user who "knows" his problem is not something dumb he is doing so he refuses to answer questions asked by Tech Support that he feels are demeaning. However, when tech support asks simple questions it is based on long experience that shows even the smartest people will at times make really dumb mistakes that may be obvious to a third party but not to the person struggling with the problem. Such mistakes must be excluded by asking specific questions and getting clear answers, with nothing taken for granted. If a user does not answer all of Tech Support's questions the incident will be closed (and charged to the user).

Why must I have the latest versions of everything and the latest service packs? Manifold uses many Microsoft system facilities to assure perfect compatibility with Windows. Problems within Microsoft code might therefore show themselves as problems encountered when running Manifold. Both Manifold and Microsoft eliminate problems by issuing service packs and by issuing newer releases. Because technical support is a limited resource, it does not make sense to waste it on figuring out and fixing problems that have already been fixed by either Manifold or Microsoft in a service pack or in a new release. Requiring that customers use the latest release of Manifold and install the latest Manifold and Microsoft service packs is the only way to guarantee that problems that have already been fixed are not at issue.

Can I get free tech support by sending a question to Sales? Tech support incidents also apply to questions of a technical support nature that are sent to sales or to any other manifold.net email address. Some users occasionally try to gain additional incidents by sending email that is clearly of a technical support nature to sales or to other manifold.net email addresses. Such emails are forwarded to tech support and will be charged as tech support incidents.

Can I ask more than one question in the same email? When more than one question is asked in the same email, Technical Support will apply an incident to each question in turn until the user runs out of incidents. An incident covers the lowest resolvable usage in Manifold, so any distinctly different questions involve different incidents. For example, a question as to why certain fields are not being transferred may be answered by Technical Support with a note to use Transfer Rules. That's one question with one answer and one incident. A follow-up question by the user asking how to set transfer rules to a particular default setting is a second question that will consume a second incident.

Does tech support assume I've read the documentation? It is unrealistic to assume that someone is attempting to use Manifold without reading the documentation. All tech support interactions proceed based on the assumption that users are in fact reading the documentation. Answers to questions therefore assume that users will use those answers as a guide to reading Help. For example, a technical support answer that cites the need to use Transfer Rules assumes that the user will read the Transfer Rules topic in Help as well as other relevant topics that branch out from that topic.

Technical support answers are therefore not a substitute for reading the documentation. If any information is available in Help, technical support will not repeat it but will assume the user will read such documentation based upon the notes in the technical support reply. Since individual subjects will often branch out from one topic into many different topics, technical support will not enumerate all topics that might be relevant: it is assumed the user will click on hyperlinks and other references to branch out through the documentation as the user sees fit.

What does a tech support incident cover? A technical support incident is any single question asked of technical support. The same incident continues no matter how many emails are exchanged until the single question is answered. "Single questions" mean those that resolve to one function or to the lowest, single, separable usage level of Manifold in a specific task.

For example, the question "How do I use Manifold?" is indeed a single question, but it is not resolvable to one function or to a matter of a single usage level in a specific task. Asking such a general question is a waste of a support incident because it will result in an equally general answer.

General questions will receive general answers, since they usually involve numerous functions or very many lower level usage levels. For example, a general question such as "How can I link to external database tables" will receive a general answer pointing out various Manifold Help topics to read, which will cost one incident. The thread does not continue into subsequent specific questions, such as, perhaps, how to operate an ODBC dialog, how to configure one's SQL Server database system and so on.

It is possible, of course, if one purchases enough support incidents to use tech support as a replacement for reading the documentation. However, such usage is very inefficient and expensive. A better idea is to get some general education in the subject matter, to read the documentation or to hire a consultant with the required expertise.
Excluded from standard support are questions related to any form of scripting, any other programming, any customization (through any of the methods that might be used to customize Manifold, such as custom datum projection grids, geocoding data extensions, or the various other customization features), SQL, Enterprise Edition features, Manifold IMS and any question involving a Runtime license. These topics require development level support incidents.

Excluded also are questions that are of a consulting or educational nature or that describe the operation of Windows in general or products other than Manifold System. Only supported are the specific functions and capabilities of Manifold.

Examples of supported questions:

- "How do I import a projected .shp file?"
- "Can Manifold import .ijk format for surfaces?"
- "How do I rotate a label?"
- "How do I link a table into a project?"
- "If I do not have enough free space in my Windows TEMP folder, will that be a problem?"

Examples of unsupported questions:

- "What is the difference between .shp files and .mid/.mif files?"
- "How do I write a script to import .ijk format for surfaces?"
- "How are labels stored in AutoCAD?"
- "How should I configure SQL Server with the right permissions for me to link a table into my project?"
- "How do I change the location of my Windows TEMP folder?"
- "What is wrong with my XML customization?"
- "Microsoft IIS won’t launch on my machine. What am I doing wrong?"

Note also that Manifold Technical Support provides technical support on Manifold products, not on Microsoft facilities or on other products. Manifold can work with many other software products. For example, one can create a linked drawing in Manifold that draws its contents from a SQL Server table. However, support on Manifold is limited to Manifold only.

For example, if you are having difficulty creating a linked drawing because your SQL Server system or Windows security is configured in a way that prevents your user login from accessing the desired SQL Server table then Manifold tech support will not undertake what is, in effect, a consulting project to help you re-configure SQL Server or diagnose the improper administrative setup of Windows.

Manifold exposes a variety of interfaces that may be used by third parties to create add-ins or other modules that work with Manifold. Manifold Technical Support does not support such third party code. For example, Manifold Technical Support does not support any add-ins from third parties, image server modules from third parties, geocoding modules from third parties or any programs utilizing Manifold runtimes.

Important: Does manifold.net support the DBMS products provided for free by DBMS vendors? No. Manifold.net does not provide any support whatsoever for installation, administration, management, configuration or use of the DBMS products provided for free by DBMS vendors.

Free packages are discussed for the convenience of users only: They are not supported by manifold.net and they are not supported by the DBMS vendors. If you want a supported DBMS installation, you must purchase a supported DBMS product from one of the DBMS vendors or you must purchase support products, if such are available, for the free DBMS product you are using from the vendor of that DBMS product. Manifold.net does not sell support products for the free DBMS products provided by DBMS vendors.

The DBMS products provided for free are each supported by a vast industry of educational and training materials. Hundreds of books, for example, have been written on SQL Server alone, ranging from texts aimed at “dummies” to those covering the most sophisticated uses imaginable. Users intending to take advantage of these DBMS products should acquire and utilize the appropriate educational materials.
Important: Do not waste technical support tokens by sending in tokens for questions about the free DBMS products. Doing so will simply waste a token to no good purpose.

Developer level support incidents may be used for questions about Enterprise Edition features used with these database products, but only for the actual Enterprise dialog. For example, a question about connecting with Enterprise Edition via Database Console to an Oracle data source will result in an answer limited to the use of the Manifold dialog, such as explaining the purpose of the Server, User Name and Password boxes. Support does not extend to explaining how you can configure users in the DBMS, how to determine what server name is being used or should be used or how to determine whether a given user has connectivity to a given data source.

What do developer technical support incidents cover? As noted in the above comments, developer level incidents cover all aspects of Manifold System, including scripting, any other programming, any customization (through any of the methods that might be used to customize Manifold, such as custom datum projection grids, geocoding data extensions, or the various other customization features), SQL, Enterprise Edition features, Manifold IMS and questions involving a Runtime license.

Excluded also are questions that are of a consulting or educational nature or that describe the operation of Windows in general or products other than Manifold System. Only supported are the specific functions and capabilities of Manifold.

Note that as with standard technical support incidents, developer incidents cover a single question that relates to one function or to the lowest separable usage level of Manifold in a specific task. General questions will get a general response. Exploration of sub-parts of that general response or more specific questions for more detailed "how to" guidance on sub-parts will require additional developer incidents.

Investigation of development problems will often involve more than one technical issue, with more than one error in usage or the need for guidance in more than one area. Sometimes a sequence of problems must be identified and solved before an overall problem can be identified and cured. That will require a sequence of developer support incidents. Each problem solved, even if only for diagnostic purposes to set aside a possible cause, uses up a developer support incident.

Developers are strongly advised not to waste support incidents on simple matters that may be found in the user manual, in examples published on the manifold.net web site or that may be found in a careful search of past threads on Internet forums for Manifold System, such as forum.manifold.net. It is also a good idea to first achieve expertise in the development environment being used so that developer incidents are not wasted on matters arising from weak understanding of the target development environment.

Developers will get maximum value when using developer support incidents if they have strong skills in the development methodology that they choose. For example, if a developer does not have strong Visual Studio expertise it is easy to waste developer incidents on questions arising from generic operation of Visual Studio that have nothing specific to do with Manifold. In such cases it would be more effective to develop greater skill in Visual Studio programming using general Microsoft educational resources such as MSDN and to save developer support incidents for issues specific to Manifold. Note that Manifold developer incidents are not a support path for non-Manifold tools such as Visual Studio.

Developer incidents are not a consultation service. Although general questions of how to approach a particular task are appropriate for a developer incident (and will receive a very general answer in reply) a developer incident cannot be used as a replacement for the services of an expert consultant. Many experts provide Manifold consulting. Recruit such experts with postings on forum.manifold.net if you need a consultant.

For example, developer level incidents may help zero in on an approach to a new project. Someone might ask, "I have the following three approaches I might take and here are the pros and cons of each as I understand them. Which do you recommend?" Although the answer to such questions will be brief and general, a pointer in the right direction from a manifold.net expert will often be very valuable for the guidance it gives. If taking this approach, keep in mind that such guidance will be brief and general. Further discussion, clarifications, assistance in writing code and so on will all consume additional incidents and will not be cost-effective compared to hiring a consultant to assist in the project.

Developer incidents are not a code-writing service. At times an answer from tech support might include snippets of code to illustrate a particular point (at the option of the tech support engineer writing the response), but this only occurs in very specific matters like the functioning of a particular object in a highly specific context. Anything other than such very specific snippets consisting of one or two lines of code should not be expected. Requesting that tech support send you a code sample for a particular task will waste an incident.

The bottom line for developer incidents is that they are a good way for people who have a mature and expert understanding of Manifold interactively and also a thorough understanding of their development environment to...
ask specific questions about specific features. For example, when you are deep inside a programming project and have hit a specific roadblock involving a particular object, a developer level incident can work magic to part the mists of confusion and get past that roadblock.

**Why don't you provide free technical support?** Regrettably, there is no such thing as "free" technical support any more than there are perpetual motion machines. If there was such a thing as free technical support we would be the first to take advantage of it!

In real life it is a very expensive proposition to keep expert engineers at hand to answer technical questions. Salaries must be paid, equipment must be provided and facilities and other resources must be funded. All that money comes from somewhere, and in a commercial company that means that every dollar for any cost associated with providing technical support comes from money paid by customers. In one way or another customers pay for technical support as that is the only source of revenue in commercial companies.

The money taken from customers to pay for technical support can come from some percentage of money paid for the product or it can come from extra fees that are charged those who use technical support or it can come from some combination of the two. But no matter what it all comes from the customer. The only question is what is the most fair and efficient way to charge customers for technical support.

Those companies who say they provide "free" technical support for a product are really telling a lie, because as we have seen above the customer is paying for that technical support in some way. In the case of companies who mean by "free" that they do not charge extra for specific uses of technical support, what is really going on is that some portion of the money all customers pay to buy the product is set aside to pay for the costs of running the technical support function. If that money were not used for technical support, the product could have been sold to customers for a lower price. The technical support in such cases is not free; it is just hidden as a cost within an inflated product price.

Since most users do not use technical support while a small percentage of users will abuse "free" technical support, what ends up happening in such situations is that everyone must pay a higher price for a product just so that some people can be subsidized with extra services paid for by other people. We don't think that is fair.

**Manifold.net** does not burden the price of Manifold System with hidden costs because we believe that doing so would be an unfair transfer of costs from some customers to other customers. If we were to provide "free" support on Manifold System, we would have to increase the cost of the product to pay for that support.

If we were to increase the cost of the product to all users to provide "free" technical support for everyone, we would in effect be charging those users who do not need technical support to provide a special service to those who do. It is especially unfair to all customers if that special service is provided (at great cost) to those who won't read documentation or invest in their own educations because they know that others will pay for those lapses.

Even setting aside egregious abuses, what one person thinks is a fair use might not be reckoned fair by those who are called upon to pay for it. For example, a consultant who is under intense time pressure to complete a task and who does not have time to read documentation thoroughly may consider that situation "business as usual" while another user may feel that part of budgeting a project is setting aside enough time to get educated in the use of required tools. The only way to respect what everyone considers fair in such circumstances is to let everyone pay for the resources they use.

We feel the fairest system is to not charge for technical support through hidden transfers but to directly and openly charge people for whatever support they choose to use. In that way, those people who prefer to use free resources like self-education, documentation and Internet forums to answer questions are not forced to pay for those who don't, and those people who find it more expedient and efficient to pay for technical support can do so.

The reader should understand that the above comments on people who abuse "free" technical support are not intended to be disrespectful to those who use technical support in the normal way. It can make sense from time to time even for the most diligent, the best managed, the best educated and the very brightest people to seek help from technical support. It's just that we think the fairest way of running matters is that when someone does decide to use technical support (for whatever reason) that person should pay their own costs of doing so.

Activation and Licensing

Activation Keys and Serial Numbers

Manifold is licensed, not sold, and your Manifold license is not without limits. It only allows you to use Manifold within the limited terms and conditions of the license. Important limitations on usage will apply, so be certain to read this topic carefully to make sure you can get maximum use of your Manifold license.

This topic talks about the nuts and bolts of activating a Manifold installation. You should read this topic before activating Manifold.

All Manifold licenses are copy protected using one of two mechanisms:

- Authorization using a Serial number and Activation keys that discourages software piracy. Manifold licenses acquired in small quantities or acquired for use on portable devices use this mechanism. Continue reading this topic to learn about the serial number and Activation key process.
- Authorization of floating licenses using a License Server. Manifold licenses acquired in larger quantities will frequently use this mechanism, which requires licensing of the Manifold System License Server product. See the Manifold System License Server topic for discussion of License Servers.

The rest of this topic assumes you are using a serial number to activate Manifold on a single computer system.

For Manifold x64 Licensees: If you have an x64 Manifold license and will be operating Manifold in either a 32-bit or a 64-bit Windows system, please read the 32-bit and 64-bit Manifold Editions topic after carefully reading this topic.

Activation Summary

Login as Administrator. Use the actual Administrator account and not some other account believed to have administrator privileges. Vista users: please read the advice in the Vista Admin Login page on the Support page of the manifold.net web site to see how to use the actual Administrator account, which might be concealed by Vista editions, such as Home edition.

Install Manifold and then launch Manifold. Check your computer's date and time to make sure it is reasonably accurate (the correct year, month and day). In the Activation dialog that pops open, provide the serial number emailed to you for the Manifold edition you have licensed. Copy the serial number from the original serial number email message and paste it into the dialog.

For the first 30 days after your serial number was issued, you can run on the serial number alone, and you can install that serial number on as many computers as you like. There is no limitation of Manifold functions running on serial number alone: all features for whatever product you have licensed are fully functional and there is no reason to activate the product.

After 30 days you will have to get an Activation key as well. When the Activation dialog launches, enter your serial number and then press the Get Activation Key via the Web button and then press Accept. Do not press the Get Activation Key via the Web button unless you really intend to get an Activation Key. Once that button is pressed the operation cannot be cancelled. Getting an Activation key terminates any return privileges you may have.

If you have licensed Business Tools, Geocoding Tools or Surface Tools extensions: launch Manifold and choose Help - Activate Extension. Enter the serial number for the extension. Get an Activation key if it is more than 30 days since the serial number was issued. Press Accept. Do this for each extension that you have.

If you have licensed Universal Edition or Ultimate Edition, all three extensions get turned on automatically when you activate your main Manifold System serial number. No need to use the Help - Activate Extension dialog with Universal Edition or Ultimate Edition.

Important: Manifold is licensed for use on one machine at a time. You get five Activation keys per serial number to allow re-installs if necessary, not to allow simultaneous use on five machines. Don't waste Activation keys. Read this entire topic carefully for tips on getting the most out of your license. Installing the same serial number
on multiple machines and using that same license on multiple machines at the same time is not allowed by your license and may result in your license being permanently revoked.

Caution: If you do not have Administrator privileges the Activation dialog will accept the Activation key and will allow you to run for that session, but the installation will not be permanently accomplished. This feature enables emergency activation of Manifold on a temporary basis if an Administrator is not available. If you do not remember to use the Activation key with an Administrator login during the 72 hour life of the Activation key you will have wasted that Activation key. If you do not have Administrator privileges when the Activation dialog is launched, Manifold will warn you that any activation will be good only for that session. Don’t make the mistake of ignoring such warnings!

Troubleshooting / Reminder for Experienced Users

This checklist is here as a quick reminder for people who are re-installing Manifold and have not read this topic for a while. New users should read this entire topic. In case of any difficulty with activation, consider the following:

- **Check the serial number**: Check the serial number at the Status Page, which is a link on the manifold.net Support page (http://store.manifold.net/online/status.aspx - check the Support page if this link has moved in the future). The Status Page will tell you whether a serial number is valid, what product it licenses, how many activations it has available, and whether it has been revoked. The most common reason a serial number has been revoked is because it has been traded in on some upgrade, like a Professional serial number being upgraded to Enterprise or a 32-bit Manifold edition upgraded to x64. In that case you should use the new serial number provided by the upgrade.

- **Typographical errors**: Copy and paste serial numbers from the original serial number email. Do not change the serial number in any way.

- **Wrong serial number**: Make sure your serial number is for the product you are trying to activate. You can't activate a Release 8.00 license with a Release 7x serial number. You can't activate a Manifold System installation using the serial number for an extension. You can't activate an x64 license with a 32-bit serial number.

- **Wrong system date**: Your system date must be accurate. Manifold will not accept serial numbers or Activation keys if the system date is not reasonably accurate.

- **Wrong machine**: A serial number and Activation key pair are good for one machine and one machine only. You can't use a serial number and Activation key on a different machine.

- **No Activation key**: A serial number will work by itself for 30 days after the date of issue. After that, you must get an Activation key as well.

- **Expired Activation key**: An Activation key is good for one machine for 72 hours only. When you get an Activation key, use it within 72 hours. If you ever need to re-install Manifold on the same machine, you cannot re-use an Activation key obtained more than 72 hours previously. You'll need to get a new Activation key.

- **Same key every 24 hours**: You must wait at least 24 hours before getting a different Activation key for the same serial number. This is to discourage piracy and to save people from accidentally using up their Activation keys.

When installing or activating Manifold, you must have a standard Windows installation in operation. Some registry "protectors," third party uninstall programs, network supervisors and other "value added" supervisory programs running on top of Windows may interfere with the installation and/or activation process. Temporarily turn off third party virus programs as well. Manifold software and these instructions assume you are running an unmodified Windows installation as shipped by Microsoft.

Keep in mind standalone Manifold licenses are licensed for standard Windows installations on physical machines. Standalone licenses are not licensed for virtual machines (use License Server with appropriate numbers of floating licenses). Likewise, Manifold is not licensed for time sharing nor can a single Manifold license be used on more than one machine at the same time.

**Assistance**

Assistance may be available for the original licensee of a Manifold license - see the Support pages in the manifold.net web site for any current free or paid technical support offerings for activation.

There are usually two ways to get assistance with serial number and/or activation questions:
• **Free support** using the procedures published in the Activation Support page in the manifold.net website.

• **Paid support** using a series of guided questions and answers with tech support, with a support token required for each such question and answer session.

All serial number and activation questions are handled by email questions sent to tech@manifold.net and must follow the procedures published in the Activation Support page in the manifold.net website. Do not contact manifold.net by letter, fax or telephone if you need assistance with any questions or issues involving serial numbers, activation or software installation. Technical support processes email inquiries from 9 to 5 PST on US business days and responds to activation questions before any other questions.

You do not need a technical support token for activation questions if you follow the procedure given in the Activation Support page. If you do not wish to follow that procedure you may use paid support to get assistance if you are the original licensee. If you contact tech support outside of the required procedure, you may be charged a tech support token with any tokens you have available being automatically consumed for such out-of-process contacts.

Please see the Activation Support page for the current procedure to follow. As a general guide for the information and procedure that web page will likely require, here is a list of information that will probably be required in your initial email message:

• Use a subject line that includes the words **Manifold** and **activation**. This will assure your message gets through any spam filters and receives maximum priority for a reply. Activation questions are answered before all other questions.

• Do **not** use any attachments. All information must be provided in ordinary text form within the body of your email message.

• Do **not** use HTML mail. Send ordinary text mail to be sure all information gets through.

• Do **not** cc any third parties. Serial number, activation and installation questions are confidential.

• At the bottom of your email you **must** include the full text of the original serial number email that provided your serial number for this license. Copy and paste this text into the body of your email. Do not attach it as an attachment. Possession of this serial number email is proof you have licensing rights to this license. If you do not have the original serial number email message you cannot get any assistance. If you do not have that serial number email, you might be able to recover it using a Key Recovery Service if available on the Manifold Online Store.

• Specify the full name of the installation file from which you installed Manifold.

• Confirm you have logged in as the Administrator account. This is especially important in Windows Vista.

• Specify the exact version of Windows you are using.

• Give the system date and time as reported by your system at the time you try activation.

• Include in your email the exact serial number, Activation key and System ID you are using. Use copy and paste to insert these into email message to avoid typographic errors.

• Provide any error messages you receive or an exact description of the problem if you received no error messages.

If you don't want to follow the procedure in the Activation Support page that is OK: if you prefer, tech support can guide you by asking you a sequence of questions, one at a time, to elicit all required information. That will require a tech support token for each such question and answer. See the Contact Tech Support page on the manifold.net website for information on purchasing and using tokens if you would prefer to use the guided process.

**Tech Tip:** The fastest way to solve any activation problem is to read and apply the instructions in this topic, followed up by a reading of the relevant support web pages on the manifold.net website such as the Activation Guide and the Activation Troubleshooting pages. Even though tech support responds very rapidly to activation questions it is faster to read even a long topic carefully since that will usually solve the problem right away.

**Your Serial Number**

Your Manifold **serial number** identifies your license to use a specified Manifold System edition or a Manifold System extension such as Business Tools, Geocoding Data or Surface Tools. A serial number specifies a product license, it is not locked or tied in any way to one person or to one machine. It is not locked or tied in any way to any product download. For that reason, it is critically important to keep your serial number secret. Don't think that any registration or activation procedure locks a serial number to you: it's always available to anyone who has it, so don't give a serial number to anyone you don't want to be able to use it.
If someone else learns your serial number, they can use it to steal your license rights from you. They can download a product installation, and use the serial number to install Manifold on other machines. When they start using the same license on different machines at the same time you might be using Manifold, it could be that your license will be revoked. Further, your Manifold license requires you to keep your serial number secret. If you disclose your serial number to third parties, you have violated your Manifold license. Each serial number is licensed to be used on one machine by one person, and a copy-protection mechanism using that serial number aims to prevent software piracy.

The purpose of a serial number is to identify the product it licenses. It's like a price tag or an SKU tag on an item in a store. A serial number works only for the product for which it was issued. For example, a Professional edition serial number cannot be used to turn on Enterprise edition. For example, a 32-bit Personal edition serial number won't turn on a 64-bit Personal x64 installation. The email in which your serial number is delivered to you makes it clear what product that serial number is for. Keep track of your serial numbers - that is easy to do if you are careful not to lose the original serial number email.

For permanent installation and continued use, your license requires you to activate your Manifold license. Activation requires fetching an Activation Key that matches the serial number. This may be done through the web in a fast and easy manner or it may be done manually if desired. Once a Manifold license is activated it will be permanently installed on one computer system and will run without time limit on that computer.

Important: Each serial number allows five activations. The purpose of those five activations is allow re-installation in case of hardware difficulties or upgrades. The purpose is not to license usage of one license on five different machines, although if someone tries that as a practical matter the limit on activations in a relaxed way limits the number of different people who can use the same serial number to install Manifold on many different machines. If you use the same serial number to try to run one Manifold license on more than one machine at the same time, Manifold will automatically revoke that serial number and you will lose your licensing rights.

The Manifold serial number and activation system is very simple; however, it is the nature of comprehensive documentation to include explicit cautions against errors encountered by some users. What may seem obvious to the reader may not be so obvious to someone else, so we have erred on the side of too much detail rather than too little. We apologize in advance for the resultant length of text that everyone thus must plow through.

Activation Keys and Serial Numbers Overview (Short)

This section provides a short Overview section of paragraphs that cover the most important points. Following the overview section is a horribly long Details section that goes into greater detail about activation. It's best to read both sections.

Administrator Permissions Required

You must have Administrator permissions in Windows 7, Windows Vista, Windows Server 2008, Windows Server 2003, Windows XP or Windows 2000 when doing any Manifold installation or activation. The easiest way to assure you have Administrator permissions is to login using the built-in Administrator login. If using XP Home in default configuration any user login with "Computer administrator" rights is OK.

Windows Vista users should login using the built-in Administrator login to avoid problems caused by logins that are thought to have Administrator permissions but do not actually have them. Vista users: please read the advice in the Vista Admin Login page on the Support page of the manifold.net web site to see how to use the actual Administrator account, which might be concealed by some Vista editions such as Home edition.

Launching Manifold for the first time or attempting to activate Manifold or a Manifold extension will display a warning message if the user account being used does not have sufficient permissions to complete the activation process.

Shut off all other programs when doing Manifold installation or activation, including any antivirus programs, network snoopers, uninstall utilities, registry protectors, Windows modifications, virtual machine middleware and other weird stuff.

If you see an Authentication Error message box pop open during any part of the activation process, something is interfering with that process. The usual problem is either failure to have Administrator permissions or failure to shut off some background program, such as an antivirus program, that interferes with activation.

Manifold is Copy-Protected
Manifold is copy-protected against software piracy, using a combination of technical means and incentives drawn from human nature to discourage people from stealing licenses. Most people who use GIS don't want to steal software, so Manifold can use a more relaxed approach to copy protection.

The Manifold copy-protection mechanism relies in part on technical mechanisms and also in part on human nature. The technical part happens when a serial number gets an allowed installation used up during the activation process. The human nature part happens when the activation process is policed by you, because you only get five activations for each license. If those five activations are used to try to cheat the license, you may find yourself without the ability to re-install Manifold when you need to because of a hardware failure or machine upgrade.

The purpose of providing five activations for each license is not to enable you to install one license on five different machines for five different users. One license can only be installed on one machine for use by one user at a time. The purpose of providing five activations is to provide the ability to re-install Manifold if you encounter a hardware failure, upgrade a machine or otherwise need to re-install Manifold for use on a different machine.

If you run out of activations, you'll probably want to buy a fresh license or more activations for an additional fee. This policy is strictly enforced, because otherwise software pirates would have no incentive not to rip off the system.

The Activation Process

For 30 days after a serial number has been issued, that serial number can be used to enable launch of Manifold on as many machines as you or whoever has the serial number wants. This initial 30 day period allows users to resolve any difficulties with software or hardware configuration on the machine they decide to use for the license. There are no limits at all: the software runs with all features enabled and no limitations. After 30 days, the Manifold installation can be activated to enable Manifold to run forever on that machine.

Note that activation cannot eliminate software piracy: that's done by detecting when the same serial number is used on more than one machine at the same time. Activation is far too relaxed a control to eliminate software piracy, but it does provide a reasonable way to discourage outright piracy in countries where software piracy is illegal.

Activation can be accomplished automatically if the machine is connected to Internet. When the Activation dialog launches, enter your serial number and then press the Get Activation Key via the Web button and then press Accept. If the machine is not connected to Internet, activation can be accomplished manually by using a different machine that is connected to the Internet.

If a Manifold installation is not activated within 30 days of the serial number being issued, Manifold will no longer launch on that machine. The serial number will still identify a Manifold license, but after 30 days it can only launch Manifold if activation is also done.

Note: The preliminary installation period before activation is required is 30 days from the date the serial number was issued. It is not 30 days from the date you receive Manifold and not 30 days from the date you install Manifold.

Activations are Limited

You only get five activations per serial number, so don't waste activations. Use the first 30 days to sort out any machine problems or other software installation problems and don't activate your Manifold installation until you are sure you want to install Manifold on a particular machine.

Plan your installations so that activations are not wasted. If you know you are going to install a larger hard disk into a particular machine, don't activate Manifold on that machine a week before you will install the larger hard disk. That will waste an activation key on only a week's functioning and then when you install the larger hard disk you'll need to use up another activation. It would be smarter to install the new hard disk first and only after do a Manifold activation.

Install anti-virus software and use prudent Windows administration policies so your machine does not get trashed by viruses every month and thus forcing an overly-frequent need to re-install Windows. If you re-install Windows, you'll use up another activation key.
Five activations are plenty if you install Manifold only on one machine as allowed by the license and if you follow prudent machine and Windows administration policies. Manifold can run for years given five activations. In fact, given Manifold's traditional upgrade policy that provides fresh activations, the provision of free activation keys over time and the availability of additional activation keys at a low cost it is really difficult to run out of activations if you take advantage of low cost or free opportunities, even if your machines die from time to time.

Once installed a Manifold license will run as long as that computer continues to operate in sufficiently unmodified form to not require re-activation. The five activations provided for a serial number enable re-installation and re-activation within a reasonable period of time; however, re-activation of old or obsolete licenses may not continue to be supported once future versions of Manifold are released. Although manifold.net may voluntarily support use of activation keys for outdated versions of Manifold for some reasonable period of time (such as three years) licensees should not expect such support.

**Purchasing Additional Activations**

The least expensive way of assuring a regular re-charge of activations, should such be needed, is to take advantage of low-cost upgrade offers whenever a new Manifold release is announced. Every few years, Manifold System has historically been upgraded to a new release and manifold.net has traditionally offered the new release to licensees of the previous release for a nominal charge for a limited period of time.

The cheapest way to get additional activations is to upgrade to the new release during the initial, low-cost offer. For example, during the first 30 days of the availability of 8.00, 7x licensees could have upgraded to 8.00 for only $50. The low upgrade fee delivered a new serial number complete with five fresh activations.

In addition, Manifold normally provides an additional activation key every year for free and provides absurdly low cost options to purchase additional activation keys in amounts that are reasonable for individual users who are observing the license. This makes it easy and inexpensive or free for law abiding users to continue to operate Manifold for years despite machine failures without encouraging software pirates to cheat the license on an industrial scale.

If you take advantage of free activations, inexpensive additional activations or upgrades to new releases, you can get a new serial number and five fresh activations for either free or for a very low cost on a regular basis for fresh activations. If you are using Manifold on one machine as permitted by the license, it is virtually impossible in ordinary usage to burn up five activations in only 18 months.

On the other hand, if you don't take advantage of upgrade offers, if you ignore free activations, if you don't take advantage of very inexpensive additional activations or if you have special needs (such as usage in harsh environments that regularly destroys machines), then your costs of getting activations could be higher, possibly much higher if you need to buy new licenses on a regular basis. If taking advantage of many opportunities for low cost or free activations does not provide sufficient activations, it could be that you will have to buy additional Manifold licenses to get the activations you need. For example, someone who operates Manifold on a portable device in an extraordinarily harsh environment such as oil well exploration or in a war zone and finds themselves having to replace their computer every month should probably budget for additional Manifold licenses as well.

**Note:** If you are a member of an organization that is operating a Manifold System License Server you normally will not have to plan for activations because you can take advantage of floating licenses administered by the License Server. This can be a highly cost effective route for some organizations.

**Activation via the Web**

When Manifold has yet to be activated, it will raise the Activation dialog every time Manifold launches. This dialog can also be launched from within Manifold by using the Help - Activate command.

To activate Manifold automatically via Internet:

- Launch Manifold and in the Activation dialog provide your serial number in the Serial number box and then press the Get Activation Key via the Web button.
- When the Activation key appears, press the Accept button. That's it!

Activating Manifold automatically via the web will connect to the Manifold activation service, will automatically send the activation server your serial number and the system ID and will fetch an Activation key, decreasing by one the number of activations allowed for that serial number in the central Manifold serial number registry.
If the serial number has already been used to accomplish five activations or if the serial number has been revoked for any reason, the attempted activation via the web will fail.

If you have previously provided a serial number to allow Manifold to run for a limited period before activation, when the Activation dialog opens it will show a masked version of the serial number, with X characters concealing the trailing portion of the serial number. You cannot use this masked version for activation. You must paste the original, complete serial number into the dialog before getting an Activation key over the web.

**Note:** When we press Get Activation Key via the Web Manifold must be able to connect to the Manifold activation web service via the web. If Manifold cannot connect to the Manifold activation web service a dialog will pop open allowing editing of proxy server configuration in case a proxy server is blocking outbound web access.

**Manual Activation**

If you prefer to activate Manifold manually you can do so as follows:

- Launch Manifold System and with the Activation dialog open, copy the System ID string. A System ID is a long alphanumeric sequence that comprises a “fingerprint” for a specific activation request.
- Visit the Manifold activation web site at [http://www.manifold.net/activation](http://www.manifold.net/activation) and paste the System ID into the System ID box. Paste the serial number provided to you for your license into the Serial number box.
- Press the Create Activation Key button and carefully write down or copy the resulting Activation key. This Activation key is good only for 72 hours from the time it is issued. After that, it is useless.
- Back in the Manifold System Activation dialog, enter your serial number and the Activation key obtained from the Manifold web site and press Accept.

Because serial numbers, System IDs and Activation keys are all long sequences of numbers and letters, it doesn't make sense to do manual activation if there is any possibility of doing activation automatically via Internet.

Note that the words used to name the various parts of the activation process are not intended to be accurate as a matter of science: they are only convenient names to refer to the process. For example, the System ID doesn't actually get computed from the hardware - it cannot be "gamed" by making an exact duplication of the hardware. It's just a way of identifying a specific activation request so that people won't burn up many Activation keys by accident.

**Wait 24 Hours between Getting Activation Keys**

**Important:** Using the same serial number within any 24 hour span to fetch an Activation key, even if the System ID is different, will result in the same Activation key. This is both a safety measure and an anti-piracy measure. It is a safety measure so that people who mindlessly push buttons multiple times on web sites or dialogs don't use up all their Activation keys in a matter of seconds, and it is an anti-piracy measure to discourage cryptographic attacks and attempted installation on multiple machines.

**Important:** The above means that you should wait at least 24 hours after getting an Activation key for your desktop machine before getting an Activation key using the same serial number to activate a Manifold license installed on your portable computer. If you don't wait 24 hours, you'll get the same Activation key back even though you used a different System ID for the portable computer. The resultant Activation key, therefore, won't work. This problem is easy to avoid: simply wait at least 24 hours after using a serial number to activate Manifold on your desktop machine before using the same serial number to activate Manifold on your portable computer.

**Checking Status of Serial Numbers**

To check the status of any particular serial number, visit the Support page on the [www.manifold.net](http://www.manifold.net) web site to find a link to the Serial Number Status page.

The status page may be used to find out if a particular serial number is a 32-bit or 64-bit serial number, whether it is still active or has been revoked (as might occur if it has been traded in for an upgrade), what product it authorizes and how many Activation keys are available. This same page may also be used to check the status of a technical support token.
A reminder: Any use of a serial number, such as checking status via the Serial Number Status page, should be done using Copy and Paste from the original serial number email. Do not use the "masked" version of the serial number that may be displayed in the Help - About dialog which ends in a series of X characters. The masked version displayed in Help - About has had the final characters altered with a series of X characters so that someone who has physical access to your computer cannot steal your Manifold serial number. The masked version displays enough of the serial number so you can determine for your internal record keeping which serial number you used on a particular machine, but not enough of the serial number for someone to be able to steal it and use it to obtain Activation keys or other wise use it.

Use Email for Activation Questions

If you have difficulty with your Manifold serial number or with the activation process, contact manifold.net by email. Follow the procedures set forth at the beginning of this topic. To discourage people who steal serial numbers and then try to get manifold.net to help them put those serial numbers to use, all serial number and activation key questions are dealt with by email only.

Runtime Licenses

If you ordered a runtime license for Manifold, then the serial number will configure operation in runtime mode only.

In runtime mode, Manifold does not provide a GUI (Graphical User Interface) for interactive use. In runtime mode, Manifold can only function as Manifold IMS or under programmatic control of another application. Attempting to launch a runtime license in interactive mode will display an error message.

Runtime editions of Manifold System make it possible for technical experts to license Manifold at reduced cost for IMS use only or for embedded use of Manifold System within programs they create. Runtime editions may be licensed at a discount from regular pricing charged for non-runtime editions.

Note: Runtime licenses are for tech professionals who have programming expertise, substantial web mastering skills and Manifold skills. Any tech support questions involving runtime licenses require a developer level technical support incident. This includes questions about activation, which normally do not require a tech support incident when non-runtime licenses are involved.

See the Runtime Licenses topic for additional information and tips when working with runtime licenses.

Serial Numbers Determine the Edition

Your serial number turns on whatever product level you have licensed. For example, a Professional Edition serial number will configure Manifold with all Professional Edition features. An Enterprise Edition serial number will configure Manifold with all Enterprise features.

Optional Extensions

Serial numbers and Activation keys are also used to "turn on" optional extensions to Manifold, either as separate installations or as part of a product bundle such as Universal Edition. For example, the Business Tools, Geocoding Tools and Surface Tools extensions are turned on using serial numbers that enable use of these extensions. If you acquire Business Tools, Geocoding Tools or Surface Tools as a separate product you will receive a serial number for each extension you licensed.

If you license Universal Edition, then one serial number will turn on all Universal features, including Business Tools, Geocoding Tools and Surface Tools.

Extensions to Manifold System use the same serial number and activation process used by the main Manifold System license. A serial number for an extension will allow use of that extension without activation for 30 days from the date that serial number was issued. After 30 days, activation will be required for continuing use of the extension.

Important Notes
Installing and activating Manifold consists of several steps:

- **Serial numbers and Activation keys are confidential information.** Keep them secret to prevent other people from stealing your license rights from you. A serial number is like a PIN code to a bank account. *Keep it secret.* There is nothing about a serial number that locks it or ties it to you, that ties it to any particular machine or that locks it or ties it to some download. If someone else learns the serial number, they can use it to steal your license rights from you, for example, by using up all of your Activation keys or by trading in your license for an upgrade. Further, your Manifold license requires you to keep your serial number secret. If you disclose your serial number to third parties, you have violated your Manifold license.

- **Do not lose your serial number.** You will need your serial number if you must ever re-install Manifold. Save a copy of the original serial number sent to you. If you lose your serial number, it may not be possible for manifold.net to provide it to you again. If it is possible at all (unlikely - don't bet on it), a fee for recovering the serial number will be charged. We're not kidding; think of that serial number as a prepaid cash card that anyone can use and if it is lost cannot be recovered.

- **Activations are limited.** Each serial number is a license for only five activations. These five activations allow you to re-install Manifold up to five times for a single license. They are **not** a license to install Manifold on five machines for use by five users but rather give you five chances to re-install Manifold on the same machine or for the same user should a disk failure or hardware or software upgrades require re-installation of Manifold. If you need more than five activations, you may have to pay to buy additional activations or to buy a new license.

- **When acquiring multiple licenses for Manifold or Manifold options,** take care to accurately **keep track of your serial numbers.** Manifold **does not** keep track of these for you. For example, if you acquire Universal Edition and also a Universal Runtime license do not confuse the two serial numbers. Keep a record (such as the original email providing the serial numbers) of which serial number corresponds to Universal Edition and which serial number corresponds to the Universal Runtime license.

- **If you don't want to keep track of many serial numbers,** acquire and use a Manifold System License Server to administer "floating" licenses that are authenticated from a single server.

**Activation Keys and Serial Numbers Details (Long!)**

The rest of this topic covers all aspects of the serial number and activation process in greater detail. It will appeal to the detail-oriented reader and will be cursed by everyone else.

**Installation and Activation Workflow**

Installing and activating Manifold consists of several steps:

- **Install Manifold from a downloaded installation file using the installation instructions that are part of the download.** You must have logged in as Administrator in Windows Vista and your login must have Administrator privileges in Windows 7, Windows Vista, Windows Server 2008, Windows Server 2003, Windows XP or Windows 2000 to install Manifold System.

- **Launch Manifold.** In the Activation dialog that pops up, provide the Manifold System serial number that was sent to you when you acquired your Manifold license. The serial number alone will enable Manifold to function for 30 days from the date the serial number was issued. You can install it on however many machines you like.

- **If you have licensed any extensions, such as Business Tools, Geocoding Tools or Surface Tools,** launching Manifold open the Help - Activate Extension dialog. Provide the serial number sent to you with your Business Tools, Geocoding Tools or Surface Tools license. Just like your main Manifold System serial number, the serial number alone will enable the extension to function for 30 days from the date the serial number was issued. **Note:** this step is not necessary with Universal Edition, since with Universal Edition the same serial number that licenses Manifold System will also automatically turn on Business Tools, Geocoding Tools and Surface Tools.

- **When you are ready to permanently install Manifold on a particular computer system,** you may activate Manifold via the Internet automatically or you may activate manually. Note that although you **could** use the system to activate one Manifold license on several machines, it is against your license to attempt to use Manifold on more than one machine at the same time. Doing so could result in your serial number being permanently revoked. It is also risky to use up activations intended for re-installation in case of hard disk crash or machine failure, because if you use up your activations you might not have a spare activation in case of machine failure when you need it.

- **If you have licensed any extensions, such as Business Tools, Geocoding Tools or Surface Tools,** when you are ready to permanently install the extension on a particular computer system, you may activate the extension via the Internet automatically or you may activate manually. **Note:** this step is not necessary with Universal Edition, since with Universal Edition by activating your Manifold System license you will also automatically activate extensions.
Please take care to keep track of your serial numbers. For example, do not confuse a Business Tools, Geocoding Tools or Surface Tools serial number with a serial number for your main Manifold license. An Activation key fetched for a particular serial number will work with that serial number only. Do not try to use an Activation key that was fetched using one serial number with a different serial number. Such errors are easy to avoid if you keep track of your serial numbers.

**When No Direct Internet Connection is Available**

If your machine is not connected to the Internet, you will want some other way of visiting the Activation web site to get an Activation key with your serial number and System ID.

If you do not have a direct Internet connection for the machine on which Manifold is installed, you can use some other machine to visit the Activation web site. Although it may be tempting to simply print out the serial number email, use a different machine to visit the Activation web site and then manually write down the resulting Activation key, it is usually a bad idea not to use Copy and Paste because of the risk of typographic errors introduced through a lot of manual handwriting. Serial numbers, System IDs and Activation keys are so long that manual entry is begging for typographic errors.

Instead, take a moment to copy your serial number and System ID into some electronic form: write the serial number and System ID into a text file that you put on a USB drive or other removable medium, or email them to yourself using some free web email service such as hotmail or gmail that can be accessed from other machines. You can then go to a machine with Internet access and open that removable medium or email, copy and paste the serial number and System ID into the Activation web site to get an Activation key and then copy and paste the Activation key back into the removable medium or reply email. Back on the installation machine you can then easily copy and paste both serial number and Activation key from the removable medium or the reply email into Manifold's Activation dialog.

If you will be traveling to locations with no Internet access whatsoever, please plan ahead and activate your copy of Manifold before departing civilization. In extreme cases, people have used satellite phones or radio to contact colleagues back in civilization, they have read to them their serial number and System ID for use by the colleague, and then finally they have gotten their colleague to read back to them an Activation key. This is obviously a formula for errors, so plan ahead to avoid such situations.

**The Activation Dialog**

The first time that Manifold launches after installation, the **Activation** dialog will open to allow you to enter the serial number for your license and, optionally, an Activation key. If you enter just a serial number Manifold will run just fine so long as it is within 30 days of the date the serial number was issued. If you enter both a serial number and an Activation key, Manifold will be permanently installed.

When the **Activation** dialog opens, it automatically shows the **System ID** computed for your machine by Manifold. The **System ID** is a unique "fingerprint" for your computer that identifies a particular activation request. Making major changes to the computer, such as replacing a hard disk, installing a new version of Windows or changing a motherboard may change the **System ID**, or they may not. Such changes may occur over the life of a computer or Manifold license (neither of which will run to the end of time), so you can obtain five activations per serial number to enable you to re-install Manifold after making such major changes that may be required by hardware failure or by upgrades to new computer equipment.

If you enter only a serial number and it is not yet 30 days past the date of issue of the serial number, Manifold will continue to function without activation until 30 days later. There is no limitation of functionality, no limitation on the number of launches or anything like that: it is the complete, full product operating with all features operating for the edition that has been licensed. Each time Manifold launches, the system will pop open the **Activation** dialog to let you know how many days remain in the preliminary installation period and to give you the opportunity to activate Manifold should you choose to do so.

When the initial 30 day period expires, Manifold will not launch unless it has been activated. Because activations are a limited resource, the purpose of the preliminary 30 day installation period is to allow users to try out different hardware configurations before they decide which computer system will be their first choice for the Manifold license.

Take your time and resolve all hardware issues during the preliminary installation period. When ready, you can activate Manifold System on the computer you intend to use for Manifold.

When entering a serial number or activating via the **Activation** dialog you must have Administrator privileges. When an Administrator enters a serial number or Activation key into the **Activation** dialog, Manifold will be
activated for all users on that machine. To make sure you have Administrator privileges login as "Administrator." Don’t assume your login has full Administrator privileges.

When running the Activation dialog, make sure no other programs are running in background except standard Microsoft Windows processes and services. Do not run anti-virus checkers, uninstallers, registry "protectors," network checkers, special administrative protection programs or other such programs. These may interfere with the activation and permanent installation process.

If desired, the Activation dialog also may be launched via the Help - Activate command.

**About Serial Numbers**

Every Manifold System license is identified by a unique, permanent serial number. The serial number encodes the Manifold System edition that is licensed and the date and time the serial number was issued. It does not encode the user, it is not tied to a particular machine and it is not tied to a particular download, so be careful not to give it to people you won’t want to be able to use it.

Serial numbers are long alphanumeric strings that look like:

```
384C86E77919-4DAEA5A0-2BC41719A85FC5F1EA49A6243055
```

For a serial number to be valid, it must be reproduced **exactly** as it was issued by manifold.net. Do not change upper case to lower case, remove hyphens, add space characters or make any other changes. A serial number must be entered as a single line without any paragraph breaks. If your email system splits long lines into two lines, make sure to reassemble the serial number as a single line when entering it into the activation web site or into the Activation dialog.

**Note:** Manifold serial numbers do not end in a series of "X" characters. If you are trying to use a serial number that ends in a series of "X" characters, you are wrongly attempting to use a masked version of the serial number that has had the last few characters concealed with "X" characters to prevent theft. Use the original serial number sent to you, not the masked version.

When a Manifold license is acquired from manifold.net, a new unique serial number is generated. The serial number will be sent to the licensee by email using the email address provided at the time of purchase. If you acquired your license directly from manifold.net, you have been emailed the serial number for your license. If you have not received the serial number by email, please see the Tech Tip below to determine what problems in your email system may be preventing you from receiving your serial number email message.

Serial numbers have four functions:

- To identify the Manifold license acquired.
- To enable up to five activations of the Manifold license, accomplished by obtaining up to five Activation keys from the Manifold Activation key server.

Your serial number specifies which edition of Manifold System has been licensed. Professional Edition licensees will have been issued a serial number that specifies Professional Edition, while Enterprise Edition licensees will have been issued a serial number that specifies Enterprise Edition.

All Manifold editions are installed from a single installation file, either for 32-bit or for x64 Manifold systems. The installation file includes all the code necessary to run any Manifold edition as well as any optional extensions available for that product. All licensees use this same installation file. After installing Manifold System the type of serial number provided to the Activation dialog will control which Manifold System edition will be launched. In addition, providing a serial number for an optional extension in the Help - Activate Extension dialog will turn on that optional extension.

Providing a Professional Edition serial number in the Activation dialog will cause Manifold to launch in Professional Edition mode. Providing an Enterprise Edition serial number will cause Manifold to launch with all Enterprise Edition features enabled. Providing a Universal Edition serial number will launch Manifold with all
Enterprise Edition features and also with Business Tools, Geocoding Tools and Surface Tools extensions enabled as well.

Serial numbers may be revoked by manifold.net if the terms of the EULA are violated. In particular, disclosing your serial number to any third party (except for the sole purpose of a one-time transfer of your license to someone else) will result in the cancellation of a serial number. If your serial number appears in any hacker lists or hacker web sites for unauthorized use of Manifold System it will be cancelled immediately. Therefore, please take care to keep your serial number secret.

Serial numbers are very important so do not lose your serial number. You cannot install Manifold without a serial number. When you receive your serial number by email, print a copy of the email and save the printed copy in a safe place. It might not be possible for manifold.net to recover your serial number if you lose it. If it is possible to recover your serial number, manifold.net will charge you a fee to recover it.

30 Day Preliminary Installation

Each serial number encodes the date it was issued as well as the period of time after that date during which Manifold System will function without activation. The limited, 30-day period of time during which Manifold will function with a serial number alone is called the preliminary installation period. The preliminary installation period runs 30 days from the date the serial number was issued. There are no limitations on the functionality of the software during that period. It is not some limited "trial edition" period or "demo" period - it is the fully complete, full power, fully operational software during that period, right from the very first day with no activation or other special procedure required.

For example, if you acquired your Manifold license from manifold.net on July 8, a serial number will have been generated on that date and sent to you. When entered into the Activation dialog, that serial number will allow Manifold to launch without activation until August 8. After August 8, the preliminary installation period will have ended and activation will be required to allow Manifold to launch.

Because serial numbers are very long, to avoid typographical errors use Windows Copy and Paste to transfer them to the Activation dialog as follows: Open the original email in which you received notice of your serial number. Highlight the serial number and choose Edit - Copy (or press CTRL-C, the Windows keyboard shortcut for "copy"). Launch Manifold and right-click into the Serial number box in the Activation dialog and choose Paste from the context menu (or, click into the box and press CTRL-V, the standard Windows keyboard shortcut for "paste"). This procedure will copy the serial number from the email and paste it into the Activation dialog without the need to manually type a long serial number.

Just like a Manifold System license, extensions such as Business Tools, Geocoding Tools and Surface Tools also use serial numbers that offer a period of preliminary installation after which activation is required for permanent installation.

Display of Serial Numbers in the Activation Dialog

During the preliminary installation period whenever Manifold is launched it will display the Activation dialog to remind you that Manifold has not yet been activated.

The Activation dialog will display the serial number used for preliminary installation, but the last few characters will be replaced with "X" characters to keep your full serial number secret. This is similar to how credit card numbers are often partially masked with * or other characters on receipts so that the receipt cannot be used to steal the credit card number, yet the credit card owner can see enough digits of the actual number to determine which credit card was used for the transaction.

If your serial number was not masked with X characters, anyone who had physical access to your machine could launch Manifold, copy the serial number and then steal it. The version masked with X characters is useless for activation, but it still contains enough unique digits to determine which serial number is in use. Manifold licensees who have many serial numbers can thus easily determine which serial number was used on which machine.

Do not let this simple privacy measure cause confusion when later activating your license. Just as the masked version of a credit card number printed on a receipt cannot be expected to work if you copy the * asterisk characters and attempt to use that number to buy something, just so the masked version of the serial number will not be able to fetch an Activation key.
When copying and pasting the serial number during activation, make sure to use the **full serial number** as originally emailed to you. Do **not** use the masked version of the serial number that appears in the Activation dialog.

**About System IDs**

The **Activation** dialog will always show the same System ID for your computer unless a major change is made to the computer's hardware or software. The System ID is a long alphanumeric string that looks like:

906578E309D5FFDCB994F8D2A8C47BCE113AE103D

If we activate Manifold via the web we don't have to worry about handling System IDs. If we choose to manually activate Manifold, we will need to copy the System ID from the Activation dialog to use at the Manifold web site for activation. The **Activation** dialog will let us use **Copy** to copy the System ID from the box in the dialog.

**Note:** The System ID box is read-only in the **Activation** dialog because the System ID is always generated by Manifold to uniquely identify an activation request.

**About Activation Keys**

An Activation key is required to permanently install Manifold to your computer system. Each Activation key is unique and matches only the one serial number and the one System ID used to obtain it.

Activation keys are very long because they encode three important pieces of information:

- The date and time the Activation key was issued.
- The serial number used to obtain the Activation key.
- The System ID used to obtain the Activation key.

Activation keys are very long alphanumeric strings that look like:

B8384D8A1C6B-4942B549-2911DE16722F3727080800EE2D2B74EC02CC5F1EA6025FECEAE

[Activation keys do not include returns - An Activation key is entirely the same line. The Activation key shown above is too long to fit into the margins of this page without a line wrap.]

Any user with a valid Manifold System serial number or with a serial number for an extension such as Business Tools, Geocoding Tools or Surface Tools may obtain an Activation key from manifold.net subject to the following conditions:

- When an Activation key is issued, it remains valid for only 72 hours after it is issued. If it is not used in the **Activation** dialog to permanently install Manifold within that 72 hour time period, it becomes useless and will no longer function to install Manifold System.
- An Activation key is valid only for the serial number used to obtain it. For example, an Activation key obtained with a Surface Tools serial number cannot be used with a Manifold System serial number. An Activation key obtained with one Manifold System serial number cannot be used with a different Manifold System serial number.
- An Activation key is valid only for the System ID used to obtain it. For example, if we obtain an Activation key generated by one System ID we will not be able to use that Activation key to activate Manifold using a different System ID.
- Each serial number can have a maximum of **five** Activation keys issued for it. The Manifold key server keeps track of how many Activation keys have been issued for each serial number. After five Activation keys are issued for a serial number, no more Activation keys will be issued. Five Activation keys are allotted per serial number in case you need to re-install Manifold at a future date as a result of system upgrades or other changes. Five Activation keys are **not** issued to enable users to violate the license by installing the same Manifold license on five different machines.
- You must have logged in as **Administrator** in Windows Vista and your login must have Administrator privileges in Windows 7, Windows Vista, Windows Server 2008, Windows Server 2003, Windows XP or Windows 2000 when launching Manifold to provide an Activation key via the Activation dialog.
Obtaining an Activation Key

The fastest, easiest way to obtain an Activation key is to launch Manifold and in the Activation dialog provide a valid Manifold serial number and then press the Get Activation Key via the Web button. Manifold will automatically reach out through Internet and get an Activation key for us. It is madness to use manual activation if our computer is connected to Internet.

If desired, we can always obtain an Activation key manually. To do so, visit the Manifold Activation key web site at

http://www.manifold.net/activation

This website requires a modern browser that can correctly handle JavaScript. You must have scripting enabled in your browser. If you have any difficulties using this website, please visit it using Microsoft Internet Explorer 5.5 or more recent edition of IE. Since you must have IE installed on your computer (even if you do not use it as your default browser) to run Manifold, you will have an IE installation available to use even if you normally use some other browser.

Visit the Manifold Activation key web page and provide a valid Manifold System serial number and the System ID for the system on which the Activation key will be used. If the serial number has not yet been used to generate the five Activation keys it is allowed, the key server will provide an Activation key. Immediately write down the Activation key in a safe place. Because the key is very long, the safest way of writing it down is to use Windows Copy and Paste to save it in a text file.

To use Copy and Paste to save the key in a text file, after the key server provides an Activation key highlight the Activation key on the web page with your mouse and choose Edit - Copy in Internet Explorer (or press CTRL-C on the keyboard) to Copy the key. Next, open a text file on your computer using Notepad or Microsoft Word or any other convenient text editor and choose Edit - Paste (or press CTRL-V on the keyboard) to Paste the key into the text document. Save the document. Save a copy of the document in a safe place, such as on a different disk drive or print out a hard copy on paper.

Once you have obtained an Activation key you can launch Manifold and provide the Activation key to the Activation dialog to permanently install Manifold System. Since the Activation key is very long, the best way to avoid typographic errors is to use Windows Copy and Paste to enter the Activation key into the Activation dialog. Open the document in which you saved the Activation key. Highlight the key and Copy it. Click on the Activation dialog and right-click into the Activation key box and Paste the key.

Because Activation keys have a limited life of only 72 hours, do not obtain an Activation key until you are ready to use it to permanently install Manifold System. Once you have obtained an Activation key, you must use it within 72 hours.

Important: Using the same serial number within any 24 hour span to fetch an Activation key, even if the System ID is different, will result in the same Activation key. This is both a safety measure and an anti-piracy measure. It is a safety measure so that people who mindlessly push buttons multiple times on web sites or dialogs don’t use up all their Activation keys in a matter of seconds, and it is an anti-piracy measure to discourage cryptographic attacks.

Important: The above means that you should wait at least 24 hours after getting an Activation key for your desktop machine before getting an Activation key using the same serial number to activate a Manifold license installed on your portable computer. If you don’t wait 24 hours, you’ll get the same Activation key back even though you used a different System ID for the portable computer. The resultant Activation key, therefore, won’t work. This problem is easy to avoid: simply wait at least 24 hours after using a serial number to activate Manifold on your desktop machine before using the same serial number to activate Manifold on your portable computer.

Administrator Privileges Required

As mentioned earlier, you must have Administrator privileges to use the Activation dialog. “Administrator” privileges are special rights granted to the Administrator user and to members of the Administrators group in Windows operating systems such as Windows 7, Windows Vista, Windows Server 2008, Windows Server 2003, Windows XP or Windows 2000 that provide user logins. If using XP Home in default configuration any user login with “Computer administrator” rights is OK.

If using Windows Vista, you must login using the actual Administrator account. Do not use some account thought to have Administrator privileges. Use the actual Administrator account. Microsoft will hide this
account in some versions of Vista, such as Vista Home, they apparently think might be used by people too stupid to be trusted to have full control over their computers. Can’t blame them. See the Vista Admin Login page in the Support page on the manifold.net web site.

Administrator privileges allow users to change anything in the system. Ordinary users do not normally have the required rights to make important changes to the system such as may be required when installing new software.

If you work in an organization where someone else configures and administers your computer, the login name you use might not have Administrator privileges on your computer. In such cases you should ask someone with Administrator privileges to login to your computer and to use their Administrator account to install Manifold System, including either preliminary installation with a serial number or permanent installation via activation.

Caution: If you do not have Administrator privileges the Activation dialog will accept the Activation key and will allow you to run for that session, but the installation will not be permanently accomplished. This feature enables emergency activation of Manifold on a temporary basis if an Administrator is not available. If you do not remember to use the Activation key with an Administrator login during the 72 hour life of the Activation key you will have wasted that Activation key. If you do not have Administrator privileges when the Activation dialog is launched, Manifold will warn you that any activation will be good only for that session. Don't make the mistake of ignoring such warnings!

Do Not Waste Activations

Five activations may seem like a lot, but they are not so many that you can afford to waste activations, even if you expect to get a fresh batch of activations every year or two through low cost upgrades, by free activations handed out from time to time or as a result of purchasing additional activations.

Over the course of two or three years it is quite possible that you might want to upgrade your computer's hard disk, install a new version of Windows, or otherwise make changes that require re-installation of Manifold System. Each installation requires activation, using up one of the five activations allowed. Because each Activation key works for only 72 hours and works only for the System ID used to fetch it, when you need to reinstall Manifold over the course of months or years you will have to use up one of the allowed activations for each installation.

If you upgrade the hard disk once and upgrade Windows once, you will use a total of three activations (one for the original installation and one each for the disk and Windows re-installations). That will leave you with only two activations available should you ever need to re-install Manifold due to unforeseen circumstances, such as a disk crash, lightning strike, power spike or other calamity.

Five activations are plenty for even very active computer users but they are not enough to waste activations thoughtlessly or to give out free copies of Manifold to friends. If you are not careful with activations, you might not have any left when you really need one.

Note that since every serial number can be used to obtain only five activations it is important to keep your serial number a secret. If anyone else learns your serial number, they could use your serial number for their own use in activation Manifold. If your serial number ever gets out to a hacker your five allowed activations will be gone overnight.

As noted earlier in this topic, if you take advantage of upgrades to new releases, you can get a new serial number and five fresh activations for a low cost. A single Manifold serial number can allow you to run your license for years, but given advances in computer hardware and software (as well as in Manifold) most people will take advantage of upgrades to renew their serial numbers from time to time.

Once installed a Manifold license will run as long as that computer continues to operate in sufficiently unmodified form to not require re-activation. The five activations provided for a serial number enable re-installation and re-activation within a reasonable period of time; however, re-activation of old or obsolete licenses may not continue to be supported once future versions of Manifold are released. Although manifold.net may voluntarily support use of activation keys for outdated versions of Manifold for some reasonable period of time (such as three years) licensees should not expect such support.

System Date Must be Accurate
Serial numbers and activation keys encode the date they were issued. They will not work with system dates that are obviously wrong such as a system date before the date of issue of the serial number or Activation key. Permanent installation also encodes the date as well. Your system date and time must be reasonably accurate (within the correct day of the date) for activation to work.

If after activation Manifold suddenly raises the **Activation** dialog again and no major hardware or software changes have been made, check the system date. If you or someone else has reset the system date to an obviously wrong date, Manifold will not launch.

**Manifold Removal and Re-Installation**

Once your Manifold System license has been activated on a particular computer, you may uninstall Manifold System using the Windows Control Panel - Add/Remove Programs applet and then later re-install your Manifold System license on that same machine without requiring any new activation. The computer system will "remember" that your Manifold System license has been activated. For example, if you installed Manifold System from the original release first issued you could uninstall that original release and then download and install an update for that same version without needing to activate again.

This doesn't work, of course, if you make changes that would destroy the activation status on your machine in any event. For example, if you uninstall Manifold and then change your hard disk or install a new version of Windows when you re-install Manifold version you may need to use an Activation key.

Note that this applies only to that same Manifold version and updates or service packs published for that same version. For example, if you have a Manifold 8 license you cannot download and install an update published for some future version such as a future Manifold product and expect that the new product will be functional. If you want to move up to a newer Manifold version you'll have to acquire a license for that newer version.

**Activating an Extension**

See the Installing and Activating a Manifold Extension topic for details on activating a Manifold extension such as a Business Tools, Geocoding Tools or Surface Tools extension.

**Installation on a Notebook Computer**

The Manifold End User License Agreement allows you to install your Manifold license both on a desktop machine and also on a portable computer used by you, so long as the two computers are not used at the same time.

Activating your license on a desktop computer and also on a portable computer will **use up two activations**. Two activations are required because each individual activation, that is, each individual Activation key, will get fetched by a different System ID that identifies that particular activation request.

It is true that installing Manifold both on a desktop computer and also on a notebook computer will consume activations at a higher rate than installation only on one computer; however, that's the choice of the user. If you choose to install both on a desktop computer and also on a portable computer, make sure to take advantage of any special upgrade offers to avoid running out of activations.

**Important:** You should **wait at least 24 hours** after getting an Activation key for your desktop machine before getting an Activation key using the same serial number to activate a Manifold license installed on your portable computer. If you don't wait 24 hours, you'll get the same Activation key back even though you used a different System ID for the portable computer. The resultant Activation key, therefore, won't work. This problem is easy to avoid: simply wait at least 24 hours after using a serial number to activate Manifold on your desktop machine before using the same serial number to activate Manifold on your portable computer.

**Example 1**

John Doe orders Manifold System via the Manifold Online Store on July 7. He receives an email with his serial number when his order is processed on July 8. A few days later he downloads the Manifold installation. He is then called away on a business trip before he has a chance to install Manifold. He is not able to install Manifold System until 22 July. John logs in as **Administrator** for all of his installation and configuration activity with Manifold.
When he launches Manifold for the first time on 22 July he is not sure exactly what to do about activation so he copies the serial number from the email sent to him and uses it to launch Manifold without activating his license. He feels he has plenty of time until August 8 to figure out what he wants to do before he needs to activate his license.

John works with several different computers. He installs Manifold on several different machines during his first few days of use to see if he needs to make any performance upgrades. He installs Manifold on his notebook computer as well. All of his machines run Windows Vista except his notebook computer, which still runs Windows XP.

After a few days he decides to upgrade his notebook (finally) to Windows Vista. To assure a clean install of Windows he reformats the hard disk and installs Windows Vista and then he begins reloading his software. He re-installs Manifold, using his serial number. Because it is not yet August 8, John can continue using his serial number to make as many preliminary installations as he wants without needing to activate his license.

As August 8 draws near, John decides that he will use Manifold on his notebook computer and on his new desktop machine at the office. Every day that he launches Manifold the Activation dialog reminds him that he has only a few days left before he must activate his license. However, John is a procrastinator and gets involved in another project for a few days.

The next time he works with Manifold is on August 12, a few days after the preliminary installation has expired. When Manifold launches it tells John the preliminary installation period has expired and asks him to provide a serial number and Activation key. John realizes it is time to stop procrastinating and to activate his license.

John launches Manifold on his desktop machine and activates his license via the web. He would like to use Manifold right away on his notebook computer, but he remembers reading the portions of this help topic that start with "Important" in bright red letters. He waits a day and a half to be sure he is past the 24 delay period required to get a new Activation key using the same serial number.

He then launches Manifold on his notebook computer and realizes that his notebook does not have a web connection. If his notebook computer had an Internet connection he could have activated his license over the web. Instead, John will have to do a manual activation.

John copies the System ID from the Activation dialog and pastes it into a text file that he saves to a zip drive plugged into one of his notebook computer's USB ports. John unplugs his zip drive from the notebook computer and plugs it into his desktop computer. He opens the text file and copies the System ID. John visits the Manifold activation web site and provides his serial number and the System ID for his notebook computer. The activation web site obligingly spits out an Activation key. John copies that Activation key to the text file in the zip drive along with a copy his serial number.

John knows the Activation key is good for only 72 hours so he does not procrastinate this time. He makes use of it right away. John plugs the zip drive back into the notebook computer and copies his serial number (copied from the original email) together with the new Activation key into the Activation dialog to permanently install Manifold on the notebook.

He now has a permanent installation on the two machines (a primary desktop machine and an optional portable computer) allowed him by the Manifold License. After all this he has used two activations. He still has three activations left on his serial number should he ever need to reinstall Manifold.

Because John doesn't want to get confused about where his licensed software is residing (and because he's straight about honoring his software licenses) he takes a moment to uninstall Manifold from all the different systems he installed it to while experimenting during the preliminary installation period. No serial number or key is required to install or to uninstall Manifold System. A serial number or activation is required only to launch Manifold.

After a year, John decides to upgrade to Windows 7. John installs Windows 7 on his desktop computer and then (logging in as Administrator) re-installs Manifold System as well. He activates that Manifold installation. He still has two more Activation keys in case he ever needs to install Manifold again. For now, he does not install Windows 7 on his notebook computer.

After another year, John purchases a new notebook computer with a hot new multi-core processor, built-in broadband cellular Internet and Windows 7 pre-installed. He installs Manifold on the new computer. He now has only one original activation left on his serial number, but he knows he gets a free activation ever year and he can always buy more activations at a low price. John's not worried because he knows he will soon upgrade to the next edition of Manifold System, which will get him a new serial number and five more activations.
After a few more months John decides to acquire a Surface Tools license. He orders Surface Tools via the Online Store and the next day receives an email giving him a serial number for Surface Tools. Because John already has decided the computer on which he will run Surface Tools he decides to activate the package right away. He logs in as Administrator, launches Manifold, launches the Help - Activate Extension dialog and copies and pastes the Surface Tools serial number into the dialog and then activates over the web. After restarting Manifold he is pleased to see the new Surface Tools features have been enabled.

Example 2

Henry Doe, John's younger brother, a student, also acquires a copy of Manifold via the Online Store. He pays no attention to the email he receives except to note the serial number. When Manifold arrives he installs it and then copies and pastes the serial number. He does not activate the license.

After a few weeks he decides it is time to get activated, but he does not "trust" web-based activation and decides to manually get an Activation key from the Manifold activation web site. When the Activation dialog pops up he copies the serial number from the dialog and attempts to get an Activation key on the web site. This does not work because Henry has copied the masked version of the serial number from the dialog, which has X characters substituted at the end. He is not using the original serial number sent to him by email. Henry, of course, has not read this topic so he thinks it is just fine to copy the masked version of the serial number from the Activation dialog.

Henry emails tech support and swears he is copying and pasting the serial number accurately. Tech support responds by asking Henry a series of detailed questions, some of which check up on typical errors (one question asks if Henry copied the serial number from the original email or from the Activation dialog). Henry is offended that they would ask him to confirm such simple things so instead of reading the questions and responding accurately, Henry just skims the questions and emails a testy reply, "Yes, I'm doing all that."

Manifold's experienced support personnel can tell right away that Henry isn't very good with details, so they ask him each question individually again in a different way and they ask him to give the exact serial number he is using. As soon as they see the X characters at the end of the serial number they solve the problem. Henry copies the serial number from the original email, gets an Activation key and activates Manifold. This experience transforms Henry for the better.

Henry realizes that perhaps things will go better if he reads the manual instead of trying to "wing it" all the time. He reads Manifold documentation every night and becomes an expert. His grades soar from C's to A's. He uses his newfound Manifold expertise to invent a new method for finding diamond-bearing Kimberlite pipes. He stakes claims on fabulously rich diamond properties and becomes very wealthy. He marries a beautiful Hollywood actress who is entranced by his continued hobby of reading Manifold documentation in depth. His friends admire his ability to cite any Manifold Help topic from memory. [This paragraph contributed by Manifold tech support].

Example 3

Jane Doe orders Manifold System via the Online Store. She receives an email providing her with a serial number. Jane downloads the Manifold installation from the Product Downloads page and installs Manifold. The first time she launches the product, the Activation dialog pops up asking her for a serial number and Activation key. She has forgotten about the serial number email message, but quickly finds it in her email inbox and pastes it into the Activation dialog. After a few more days she decides to permanently install the package so she activates Manifold over the web.

After a few weeks of work, Jane encounters problems with her Windows system when an application she recently installed is not working properly. She decides to simplify her system to see what could be causing the problem by uninstalling some of the applications she has installed recently. She uninstalls Manifold using the Windows Control Panel Add / Remove Programs dialog. Removing Manifold proves it is not the problem. After removing a few other applications she traces the problem to a freeware screen saver utility. After cursing lame freeware authors she removes the offending utility.

To re-install Manifold she installs it again from the installation file she previously downloaded. When she launches Manifold, it automatically launches without the need to enter a serial number or an Activation key since Manifold has already been permanently installed on this computer system. If Jane had re-installed Windows or made other substantial changes (such as rolling back her registry or other major alterations), she might have had to use an activation to re-activate Manifold System, but since she has not made any major changes everything works automatically for her.
A month or two later when Manifold launches it tells Jane that a new update is available. She downloads the update, uninstalls the previous version of Manifold and then installs the update following the update's installation instructions. Manifold launches without opening any activation dialog. Once again there is no need for Jane to enter a new serial number or to re-activate Manifold.

Internet Map Server

When Manifold is running as an Internet Map Server (IMS) it will not raise the Activation dialog. Therefore, before attempting to use Manifold in IMS mode you must launch Manifold interactively at least once to provide a serial number for preliminary installation, or a serial number with activation for permanent installation. Alternately, you may use command line activation (see below) to provide a serial number and Activation key.

Runtime Licenses

Every Manifold installation will launch with the Activation dialog when it is first launched. When a serial number is provided during that first launch the Manifold installation will become the edition designated by that serial number. Providing a runtime serial number will configure that Manifold installation as a runtime edition.

Because runtime licenses do not have a GUI once they are configured with a serial number they are normally activated when Manifold is first launched. After a runtime license is configured with a runtime serial number, Manifold will not launch interactively so the Activation dialog will not appear during the 30 initial days of operation on serial number alone.

After the first 30 days if a runtime license running on serial number alone is launched then the Activation dialog will be raised. This will enable re-entry of the serial number and activation. However, because it is a messy situation to launch a runtime license with a serial number alone and then have to wait for up to 30 days to get the Activation dialog back again, to avoid such hassles people will normally activate a runtime license the first time Manifold is launched. Strictly speaking they don't have to, but it is such a common sense convenience that's what most people do.

Command Line Activation

Manifold may be activated from a Windows command line. Command line activation options are a relatively limited tool and are only intended to be used to switch editions of Manifold that are installed on the same machine or to force a non-interactive edition (such as a runtime or a License Server installation) to raise the Activation dialog.

Command line activation allows some administrative tasks to be accomplished more easily:

- IT administrators may switch editions of Manifold installed on machines in their network using automated tools, without requiring manual action by users. However, most IT administrators will use the Manifold License Server product to simplify life even further.
- Application developers or Manifold IMS administrators using runtime editions or IT administrators using License Server editions may switch the edition of Manifold installed on a machine from a non-interactive license to a regular, interactive license, such as Professional Edition or Enterprise Edition.

There are two command line switches for activation. One switch is for activation of Manifold System itself and the other switch is used to activate an extension:

```
manifold.exe /activate:serial,key
```

Activate Manifold System.

```
manifold.exe /activateExt:serial,key
```

Activate an extension.

In the above, `serial` is the serial number and `key` is the Activation key. Because a System ID must be noted in order to get an Activation key with a serial number, the user must be able to launch Manifold interactively at least once on a machine to obtain the System ID.

Supplying an invalid serial number or a valid serial number without an Activation key will pop open the Activation dialog. This is a handy way of forcing a non-interactive Manifold installation to raise the Activation dialog so that the System ID may be obtained. For example, using the command line switch:
...will pop open the Activation dialog since "dialog" is not a valid serial number.

While command line activation options can be used to automate the deployment of Manifold licenses within an organization, Manifold System License Server provides a significantly easier and much more efficient way of doing so. The License Server allows installation of Manifold without individual activation. Instead, licenses are authenticated by connecting to the centralized License Server using the pool of available licenses.

See the Command Line Options topic for other command line options.

Frequently Asked Questions (FAQ)

Someone else got my Manifold license for me and manifold.net tech support will not assist me with activation. How do I get assistance with activation? Contact whoever got your license for you for assistance. manifold.net will only support the original licensee using the original email to which serial numbers were sent. There are two main reasons for this. First, serial numbers and activation keys are confidential information and manifold.net will not risk assisting anyone who may be using someone else's license without authorization. Second, manifold.net provided important information about activation to the original licensee but has no control over whether the original licensee passed on that information to you. If you are in an organization the designated licensee is the sole and exclusive contact with manifold.net.

How do I transfer my Manifold license from one computer to a different computer? Login as Administrator for all of the following steps: Step 1 - Make sure you have your original serial number email so you can copy and paste your serial number without typographical errors. Step 2 - Check the serial number on the serial number status page in the Manifold support web page to verify you have an activation remaining. Step 3 - Uninstall Manifold from the old computer using the Windows Control Panel's applet for uninstalling programs. Step 4 - Download the latest Manifold installation file for your version of Manifold onto the new computer and install it. Step 5 - Launch Manifold and provide your serial number, getting an Activation key.

Is my Manifold license locked to me? Can I transfer my license to another user? Manifold installation files downloaded from the website, licenses, serial numbers or activation keys aren't locked to or bound to or identified with any specific user. That makes it easy for companies and resellers to procure software for distribution within their companies or to their clients. But that also means that anyone who has a serial number for a license can use it, so be careful not to give out a serial number to anyone who you don't trust to use it. But that also makes it easy to transfer a license you have obtained: simply uninstall Manifold from your computer and then give your serial number to the person you want to have it. The transfer is then just like transferring a Manifold license from one computer to a different computer. Do not continue using Manifold because if the same serial number is run simultaneously on multiple computers that is a violation of your license and could result in the serial number being revoked automatically.

Must I activate Manifold to get a fully operational license or to remove limitations in the license? No. There is no such thing as a limited Manifold license that is a "demo" or "trial" license with any sort of limitation. Every license issued by Manifold is a full-power, fully complete license right from the very first day and requires no activation for fully functional operation. If you have any difficulty operating the software, don't think you need to activate it to turn on some feature that appears not to be running. That's not the problem (to find the problem, consult the user manual or contact tech support for assistance). Activation is purely a mechanism that allows easy experimentation with different computer configurations during the first 30 days of a license's life while discouraging piracy thereafter, and it provides a way of keeping track of which licenses, for those which are refundable under the limited 30-day money-back guarantee, might still qualify for a refund. For the first thirty days of every license's life no activation is required. You may install it on however machines you like during the first 30 days of the life of a license. There is no need to activate to "turn on" any feature or to remove any limitation. Every license is full power, fully functional, all the time. Note that this is a very different approach than some software, which provides a limited "trial" software version that has some restricted or missing capabilities, such as disabled printing or disabled file saving or some limited number of launches or some other limitation, until an activation code or other authorization code is provided. Manifold software is always fully functional all of the time.

Can't I just keep setting my system clock back every 30 days to run forever without activation? Sure, if you don't mind doing that. Manifold will run forever in that case as a fully operational license with no limitations and no need to activate. Some users do just that if they find Activation is inconvenient, or just if they want to try out different combinations of hardware. Manifold uses a relaxed approach to copy protection that is not as harsh as some schemes that won't allow such relaxed, full-power operation without utilizing a specialized licensing procedure or which limit the software to a limited number of launches, a limited number of saves or otherwise limit functionality. However, you have several other options. You can simply reset your system clock that is something easy to get confused about or it may interfere with the operation of other software that takes a harsher approach to copy protection. It's not a good idea to use this method to share one Manifold license with your friends or to try to run one Manifold license on many machines because if the same serial number is run simultaneously on multiple computers that is a violation of your license and could result in the serial number being revoked automatically.
Activation and Licensing

I have licensed a 64-bit Manifold edition. Can I use my 64-bit license serial number to activate a 32-bit Manifold installation? Yes. The serial number you get for a 64-bit Manifold license can activate either a 64-bit or a 32-bit Manifold installation. For example, suppose you have 32-bit Windows computer today but you know in a few months you'll be upgrading to 64-bit Windows. You could use a 32-bit Manifold installation file to install 32-bit Manifold on your 32-bit Windows system and use the serial number from a 64-bit Manifold license to activate it. In a few months when you upgrade your computer to 64-bit Windows you could use a 64-bit Manifold installation file to install 64-bit Manifold on your 64-bit Windows system and use your 64-bit Manifold license serial number to activate it.

I acquired my license and received a serial number more than thirty days ago. Can I still install Manifold System? Yes. Serial numbers don't expire over time. You can run Manifold System but you will need to activate your installation since the time period available for preliminary installation has already expired. Launch Manifold and in the Activation dialog provide the serial number and then get an Activation key via the web. Done!

I received my serial number a long time ago and never got around to installing Manifold. Can I still activate my license? Yes. For the purpose of activation, serial numbers never expire. As long as you haven't used up the activations allotted to your serial number, you can activate the license using your serial number. Note that re-activation of old or obsolete licenses may not continue to be supported once future versions of Manifold are released. Although manifold.net may voluntarily support use of activation keys for outdated versions of Manifold for some reasonable period of time (such as three years) licensees should not expect such support.

After a previously successful installation and activation I need to activate again, but the System ID box is empty. Something has changed in your system that has made it impossible for Manifold to find a .NET assembly that needs to be used. Uninstall Manifold and then reinstall it. If it doesn't fix the problem, try repairing the Microsoft .NET framework using the Microsoft control panel applet, and then uninstall Manifold and reinstall it.

I tried to get an Activation key on the Manifold activation web site with my serial number and the web site would not give me one. Check the obvious first:

- Did you correctly enter the serial number? Use Copy and Paste to avoid typographic errors. Include the hyphens, do not change upper case to lower case and make sure to otherwise enter the serial number exactly as it was given to you.
- Did you provide the System ID copied exactly from the Activation dialog for the target system?
- Copy the serial number from the original serial number email message. Don't copy it from the Activation dialog where it is masked off by XXX characters at the end so that it cannot be stolen.
- Did you obtain the serial number from Manifold? If you obtained your license and serial number from a third party it might not be a valid serial number.
- Has the serial number been used up? You can only get five Activation keys for each serial number at the activation web site. If you or anyone else has been getting Activation keys with that serial number, it could be used up. Keep in mind that if you or someone else has been fetching Activation keys using the Get Activation Key via the Web button, each time you activate Manifold in that manner you use up one of your five Activation keys.
- Has the serial number been revoked? If you did not pay your purchase order or have reversed ("charged back") your credit card payment to Manifold, your serial number has been revoked. As they say, “no pay, no play!” If your serial number has been published on Internet or has appeared in hacker lists of serial numbers used to steal software, it has also been revoked.
- Has your serial number been traded in on an upgrade? If you have upgraded from a 32-bit license to a 64-bit license the old 32-bit license is no more. An upgrade is not a free second license: it is a replacement for a previous license.
- Some serial numbers allow a limited period of operation without the ability to obtain an Activation key. Such serial numbers are issued to journalists or other reviewers to allow a limited period of operation. If you have such a serial number the key server will not give you an Activation key.
- Try using Internet Explorer 5.5 or 6.0 as your browser. Some other browsers have JavaScript errors without reporting those errors. Firefox may be a cool browser, but some versions of it are not able to deal with elementary javascript without errors.
- Make sure scripting is enabled in your browser. Some people turn off scripting for security reasons, but that prevents the Activation web site from working.
- Make sure you are using a PC. If you are using a Mac, make sure your browser settings are the same as would be used on Windows.

I tried to visit the Activation web site and got a Javascript error. Use a browser that functions correctly with Javascript. Since you must have IE6 installed for Manifold, we suggest using Internet Explorer. If you are using a non-Microsoft browser, try using IE.
If I accidentally press the "Create New Activation Key" button twice on the Activation Keys web page, will I waste an Activation key? No. Once an Activation key is generated for a serial number, if the same serial number is used again the web site will return that same Activation key throughout the first 24 hours of the 72 hour life of that Activation key. If you press the button several times you will get the same key back several times. This is a safety measure to avoid wasting keys. The same Activation key will be returned even if you use a different System ID with the same serial number so if you intend to install the same serial number on a desktop machine and also on a portable computer (the only licensed use of the same serial number on more than one machine), you should wait at least 24 hours between activating the desktop machine and getting an Activation key for the portable computer.

I entered my serial number into the Activation dialog but Manifold will not launch or reports that the serial number is invalid. Check the obvious first, including the Troubleshooting section at the top of this topic:

- Did you correctly enter the serial number? Use Copy and Paste to avoid typographic errors.
- Did you obtain the serial number from Manifold? If you obtained your license and serial number from a third party it might not be a valid serial number.
- Has the preliminary installation period expired? If it is after 30 days from the date the serial number was created and you don't want to reset your system clock accurately you will also need an Activation key to activate Manifold.
- Is your system date set accurately?
- Are you trying to use a serial number issued for an extension (such as Business Tools, Geocoding Tools or Surface Tools) to activate Manifold System itself, or vice versa are you trying to use a Manifold System serial number to activate an extension?
- If you are entering both a serial number and an Activation key, have you mixed up a serial number for one license with an Activation key that was fetched using a different serial number? Activation keys only work with the serial number with which they were fetched.
- A specific case of the above error: are you trying to use a serial number for a 32-bit Manifold product with a 64-bit Manifold installation? Running Manifold System in full 64-bits requires purchasing an x64 Manifold System product to get a 64-bit serial number. See the 32-bit and 64-bit Manifold Editions topic.
- Is the serial number for the same Manifold release that has been installed? You can't use a 7x serial number to launch an 8.00 installation, for example.

I entered a serial number and Activation key and Manifold worked OK, but now it does not. It is most likely that you did not use the Administrator login in Windows or that your login did not have Administrator privileges in Windows 7, Windows Vista, Windows Server 2008, Windows Server 2003, Windows XP or Windows 2000 when you used the Activation dialog to permanently install Manifold. The usual scenario is as follows:

- The user has a non-Administrator account that they use for daily operation.
- When first installing Manifold, the user reads all the material, logs in as Administrator and installs the product. When the Activation dialog launches, the user provides a serial number (only) and the product launches OK.
- Over the next few days and weeks the user logs in via the non-Administrator account and continues using the system in a routine way, including launching and using Manifold.
- One day when launching Manifold, the Activation dialog launches and announces to the user that activation is required. This happens because it has been 30 days since the serial number has been issued so now it is time to activate the license for continued operation.
- Right away, the user presses the Get Activation Key via the Web button to fetch an Activation key and presses the Accept button, ignoring all warnings about not having Administrator privileges.
- Manifold launches OK, but it is running in emergency mode for one session only.
- However, that previous step was an error because the user was logged in using his or her routine non-Administrator account. What has happened is that because it was several days or weeks after the initial installation, the user has forgotten the warnings to log in as Administrator when either a) installing Manifold or b) providing keys to the Activation dialog.
- Manifold will accept an Activation key in non-Administrator mode, but it only does so for that session as an emergency way of allowing Manifold to function even if the user cannot find someone right away with Administrator privileges.
- If you are sure it is not an Administrator privileges issue, something was changed in your system (Windows re-installation, restore from pre-installation image, hard disk changed, etc.). Someone might have tried to jump back to a previous Restore point in Windows, for example.

I activated Manifold on my laptop running XP and it ran OK for years but now it has suddenly stopped working and has raised the Activation dialog. I have installed no new programs or made any changes to my computer. What is the problem? Something has destroyed the activation status on your computer. The most common reasons:
• The system date has changed. Old laptops can have unstable clocks, so you might find your system date is not today's date. Reset the clock to today's date to solve the problem.
• A Windows restore has been done to a point before Manifold activation. Undo the restore.
• "I have installed no new programs or made any changes to my computer." Often said, but never believed by the veteran tech support engineer. People install new programs all the time. Every time you visit a web site with "active" content you install new programs, to name just one of millions of ways in which people install new programs without realizing it. Some such programs can have very destructive effects.
• There has indeed been a change in your Windows system that can affect activation status. For the same reason people don't realize when they get hit with a virus, it is easily possible that without realizing it you have installed some program or virus that has changed things. Some viruses make significant alterations in the registry and elsewhere as part of attempting to prevent anti-virus software from eradicating them, and such viruses can affect activation due to the havoc they wreak upon Windows.
• There has been a serious change in your hardware or intermittent failure of key components. Setting aside the obvious case of someone who changes hard disks, changes the motherboard and upgrades from XP to Vista and still insists "I've made no changes," there can occur very serious changes in hardware that users might not realize have happened. Especially with aging laptops it might be the case that your hard disk or disk controller or motherboard is failing in a way that has blotted out key sectors on your disk, much as degenerative dementia blots out parts of human brain function. In computers as in humans this can be a destructive result of the aging process.
• You are utilizing virtualization software and have forgotten that each such virtual machine is a true machine: bring those machines into existence and out and you are indeed changing your computer.

Unfortunately, given the inherent complexities of the latter three scenarios it is up to you to debug what is going on with your system. If you are sure the hardware is not failing, the best course to recover from chaos caused by unknown programs or viruses is to re-format the hard disk, to reload Windows from original Microsoft media (to avoid infected backups), to install industrial-grade antivirus software with current virus definitions and then finally to restore data and programs from backup media after careful screening for viruses. You can then re-install Manifold and use one of your remaining activations to activate the new Manifold installation.

I have several Manifold System licenses and serial numbers. Can I freely mix Activation keys? No. Each Activation key will work only with the serial number and System ID that was used to obtain it from the Manifold Activation key server.

I entered my serial number and Activation key into the Activation dialog but Manifold will not launch or the serial number and key are not accepted. Check the obvious first:
• Did you correctly enter the serial number and the Activation key? Use Copy and Paste to avoid typographic errors. Be sure you are copying the entire string and pasting correctly without any errors. Do not make any changes, such as removing hyphens or changing from upper to lower case. Use the original serial number, not the version masked off with XXX characters at the end.
• If you own multiple Manifold licenses, have you mixed up a serial number for one license with an Activation key that was fetched using a different serial number? Activation keys only work with the original serial number, not the version masked off with XXX characters at the end.
• Did you obtain the Activation key from the Manifold Activation key web page? If you obtained your serial number or Activation key from a third party it may not be valid.
• Have 72 hours passed since the time the Activation key was created by the Manifold Activation key web page? If so, the Activation key has expired. You will need to get another Activation key.
• Are you trying to use a serial number and Activation key issued for an extension (such as Business Tools, Geocoding Tools or Surface Tools) to activate Manifold System itself, or vice versa are you trying to use a Manifold System serial number to activate an extension?
• Is the system date reasonably accurate? Serial numbers and Activation keys encode the date they were issued and will not work with system dates that are obviously wrong such as a system date before the date of issue of the serial number or Activation key.
• Are you using a nonstandard program that replaces or modifies the standard Windows interface so that Copy and Paste operations are modified?
• Are you running any programs in background other than standard Windows processes and services? When running the Activation dialog, make sure no other programs are running in background except standard Microsoft Windows processes and services. Do not run anti-virus checkers, uninstallers, registry "protectors," network checkers, special administrative protection programs or other such programs. These may interfere with the activation and permanent installation process.

I lost my serial number. Can you help? Possibly yes. However, a key recovery fee will be charged for this service. See the products listing page in the main manifold.net web site for prices charged for Key Recovery services, if available, as well as terms and conditions for such recovery.
Can I transfer a Manifold System license from one computer to another? During the preliminary installation period you can install Manifold System on any computer system using only the serial number. After the preliminary installation period has expired, a license transfer will require normally require reinstalling Manifold System and using up an activation.

Can I upgrade my computer system without re-installing Manifold? As long as you don’t make major changes in hardware or software, probably yes. Simple upgrades such as adding a new graphics card will normally not require a re-installation of Manifold. Some changes in hard disk structure will require re-installation of Manifold and the use of an activation. The only way to know for sure is to try. Accordingly, it is wise to do any major upgrades during the period of preliminary installation.

Can I upgrade Windows without re-installing Manifold? In most cases, no. Installing a new version of Windows will usually require a re-installation of Manifold and use of an activation.

Can I remove and re-install Manifold without a new activation? Yes. Even if you remove Manifold, on the next installation Manifold will know that you have already activated Manifold on this system so it will not require a new activation, provided that you have not made any changes to your system in between the uninstall and the re-install that would wipe out activation.

Can I install a new Manifold serial number without a new activation? No. Installing a new serial number requires a new activation. Activation works only for a limited time for the serial number and system ID used to fetch the key. For example, if you have installed Professional Edition and you would like to switch to Enterprise Edition you will need an Enterprise Edition serial number and a fresh activation for that new Enterprise Edition serial number. See the Help - Activate topic for discussion and an example.

Can I install a Manifold Update or Service Pack without a new Activation key? Yes. You can uninstall the previous Manifold installation and then install the update, which also may be known as a Service Pack (SP), without requiring a new activation. The system will “remember” the previous activation even though Manifold was uninstalled. Of course, this assumes you have made no other changes to your system that would require a new activation in between uninstalling the previous Manifold installation and then installing the update. You cannot, for example, uninstall the previous Manifold installation, install a new version of Windows, and then expect to install an update without requiring an activation.

Can I use a serial number from one edition of Manifold with a newer edition of Manifold? No. Each new major release of Manifold requires a new serial number.

What is a “substantial” change in Windows that requires a new Activation key? Any re-installation of Windows or upgrade to a different edition of Windows will probably require a new activation. Other major configuration changes (such as Registry configuration or rollback to a pre-Manifold restore point) may require a new activation.

Why do Activation keys have a limited life of 72 hours? Activation keys have a limited life of 72 hours from the time they are issued in order to discourage attempts to clone installations in violation of the license and to otherwise discourage software piracy.

Why are serial numbers limited to five activations? To discourage piracy. The preliminary installation period allows time to sort out the initial Manifold installation before the first activation is used. After that, four additional activations will allow users to re-install should Manifold ever need to be re-installed in the future. Five activations are plenty to allow users to deal with changing system configurations for a single license, but they are not so many that people can afford to be careless with them or to give them away to enable piracy. It’s not a terrible limit since Manifold gives out a free activation every year and provides additional activations at absurdly low prices.

I upgrade my computer system frequently and I need more than five activations. What do I do? Take advantage of free activations, low cost additional activations or additional activations through upgrades. If taking advantage of all that is not enough, you must buy additional Manifold licenses to get the activations you need. If you are a member of an organization that is operating a Manifold System License Server you can avoid burning up activations by taking advantage of the License Server.

What is to prevent me from giving my serial number to four friends who each then obtain an activation? If you are willing to break the law, nothing prevents you from doing so except your own self-interest. From a legal perspective, that is a crime and a violation of the License agreement. Engaging in software piracy risks criminal and civil penalties. As a practical matter, it is risky to do because your friends may use up the activations you need yourself and they probably aren’t going to bother to call you to coordinate their use of Manifold with you so that the same serial number is not used at the same time on different installations. If you ever need an activation
to re-install Manifold (if case your hard disk blows up or if you must re-install Windows) you might not have an activation remaining. In addition, whenever you disclose your serial number to anyone else you take the risk that they will not keep it secret. The sort of person who trades serial numbers to commit software piracy is often the sort of person who cannot resist passing on the serial number to yet another friend. Before you know it, your license rights could be used up. Your serial number might even be published on a hacker web site and your serial number could be cancelled by manifold.net, permanently denying you the ability to use Manifold System. Last but not least, if you disclose your serial number to someone else they might use it to upgrade to some wonderful new Manifold release before you can do so. They'll have the wonderful new release and you won't be able to get it, because your serial number will have been revoked when it was traded in on an upgrade. It is easy to avoid such problems by keeping your serial number secret.

Can I use the same Activation key to install Manifold to more than one system during the 72-hour period the key is enabled? No, because each Activation key is fetched by the System ID that identifies that request.

What happens if I run the same license on more than one machine at the same time? Do not violate the License by using the same license on more than one machine at the same time. Manifold System can detect when other instances of the same license are running on machines that are accessible to it. If you use the same license on multiple machines at one time, sooner or later Manifold will automatically cancel that serial number and will cease functioning. To discourage software pirates who attempt to find and disable such protective measures, this auto-detection function might be set to a very long trigger time: it could be weeks or months of simultaneous usage before Manifold decides that "enough is enough" and permanently stops functioning.

My organization needs to use many Manifold licenses. How should I install them? Use the Manifold System License Server product to centrally manage your licenses.

I acquired my Manifold license from a reseller and have not received a serial number. Can manifold.net help me? No. If you acquired your Manifold license from a third party and have not received your serial number you must contact the third party to resolve the difficulty. manifold.net will not intervene in a dispute between you and a third party. manifold.net does not enter into any special agreements with any dealers or distributors to represent the company so any third party who offers to transfer a Manifold license to you is acting on their own.

What happens if my serial number is revoked? If your serial number is cancelled or revoked you will not be able to obtain activations with that serial number. In addition, sooner or later your Manifold System license will cease operating.

How might my serial number be revoked? The most frequent reason is that it has been traded in to get an upgrade. For example, if you upgrade a Professional license to an Enterprise license the Professional serial number will revoke the Enterprise license. Likewise, upgrading a 32-bit serial number to a 64-bit serial number will revoke the 32-bit serial number. Serial numbers may also be revoked for a variety of business or legal reasons: non-payment, such as failure to pay a purchase order or a charge-back on a credit card transaction; automatic cancellation when Manifold itself detects multiple simultaneous usage of the same serial number on a different machine; cancellation for violation of the EULA, for example, cancellation by manifold.net if your serial number appears in a public forum such as an Internet posting.

I want to acquire a Manifold license and run it forever, or at least for decades. Can that be done? Sure. Once installed a Manifold license will run as long as that computer continues to operate in sufficiently unmodified form to not require re-activation. If you are running exactly the same computer hardware without failures you can indeed run Manifold for decades. In addition, the five activations provided for a serial number enable re-installation and re-activation within a reasonable period of time; however, re-activation of old or obsolete licenses in the case of machines that fail on a regular basis may not continue to be supported once future versions of Manifold are released. Although manifold.net may voluntarily support use of activation keys for outdated versions of Manifold for some reasonable period of time (such as two or three years) licensees should not expect such support. You should therefore budget for acquiring updates from time to time to enable Manifold installation on newer computer systems or on a repaired computer system if over the years hardware failures require re-installation.

Serial Numbers not Received by Email

When an order is processed for Manifold System the serial number for that license will be sent out by email to the email address given in the order. If you have not received your serial number by email from manifold.net check your email system for obvious errors. Typical errors include:

- You did not provide an email address when you acquired your Manifold license. This happens occasionally when purchasing groups neglect to provide an email address on a purchase order. If so, manifold.net is waiting to hear from you to learn what email address you wish to use.
• You acquired your license from a third party, such as a reseller or previous licensee. In that case, you must contact that third party for any questions about serial numbers as manifold.net is not part of your business deal with that third party. Note that manifold.net does not enter into any agency or reseller agreements or "authorize" any dealers, so if you acquired a Manifold license from some third party that third party is in no way an agent or representative of manifold.net.

• A nonexistent email address (typographical error or otherwise invalid email address) was supplied with your order. Tech tip: check the invoice and the packing slip sent to you in hard copy with the product - it will contain the email address you provided. Check that printed email address carefully for typos to be sure it is the email address you are using.

• You have forgotten to check the inbox for the email address you supplied. Tech Tip: If your Outlook application is set up to check multiple addresses, make sure the address you provided is one that is being checked for inbound mail.

• You accidentally deleted the email without realizing it contained your serial number. Tech Tip: Take a look in your Deleted Items folder to see if it is there.

• Your mailbox is over quota and so your ISP is rejecting inbound emails.

• You have not used the email address provided to manifold.net for a long time and so your email provider has suspended it as inactive.

• The email address supplied to manifold.net has been forwarded to a different email address and the forwarding is not working.

• You have changed your email system recently and it is not working (relaying not permitted, etc.) in the new configuration.

• You have created a new email address just for business dealings with manifold.net and it is not working. Tech tip: Don't use a previously-unused email address that's not been verified to work. manifold.net won't spam you or share your email address with anyone else.

• You or your ISP have installed anti-spam technology that is too aggressive and is blocking the emails being sent to you by manifold.net. Check any "spam" or "bulk mail" folders into which your spam filter may be placing emails prior to deletion.

• Your or your ISP have installed a virus or other filter that is too aggressive and is blocking manifold.net emails because it thinks they contain scripts or executables (they don't).

• You use Outlook and have applied some mail-handling rules that are deleting inbound messages from manifold.net or moving them to a folder that you do not view.

• You or your ISP have installed a "blacklist" filter that blocks emails originating from IP addresses used by Manifold email servers or email servers run by Manifold's ISP if such IP addresses are reported by a centralized listing organization to be spam servers. [Note that such filters are pointless since spammers routinely forge the origin of their spam to make it look like it comes from legitimate IP addresses.]

• You have placed manifold.net as a domain on your anti-spam whitelist but have not allowed email from other domains used by our email servers or from dedicated IP addresses.

• You or your ISP have installed spam-blocking technology that requires the sender to reply to a confirmation email or to visit some web site and enter a code. The Online Store and other Manifold servers that send out serial number emails are machines that cannot respond to return emails requiring confirmation.

• Someone else, such as a centralized IT department, runs your email system and is being a completely uncooperative bureaucrat about telling you what stupid tricks they use to prevent you from getting legitimate email. Tech tip: get your own free HTML-based email account and use that to bypass the IT department.

Everyone on the planet is totally annoyed about spam so it is natural that people want to use anti-spam technology to help get rid of it. Unfortunately, no anti-spam technology is perfect so you may have to exercise some manual supervision over your anti-spam strategy to make sure it does not filter out legitimate emails from manifold.net that you want to receive.

If one of the problems above is in play, that can lead to a very frustrating experience with communications. For example, a customer sometimes without realizing it will have massive spam filters in place that prevent any communications from manifold.net getting through. The customer does not receive the serial number email and then when the customer writes to sales@manifold.net to complain, he or she does not get any reply. The customer sends repeated emails, each of which gets angrier and angrier. The problem, of course, is that if the customer has some spam filter that rejects emails from manifold.net then no matter how often manifold.net replies the customer will not get those replies.

The solution to the above problem is to use some temporary, HTML-based, free email address from hotmail.com, yahoo.com or Google's gmail to correspond with manifold.net.
The worst situation is when someone for ego or broken logic reasons is not willing to consider the possibility that something about his or her email system is preventing email from manifold.net from being delivered. There are two classic cases: the first case being the person who thinks that because they receive plenty of emails from other people there cannot be anything wrong with their email setup. This is the "broken logic" problem because obviously you won't know about the many emails you don't get if you never get them.

The second typical case happens when the person having email reception problems is the person who has set up the email system and has ego problems considering that something might not be quite right. Some people, for example, seem to have a knack for setting up their own email servers that are configured with all sorts of tricky arrangements that don't correctly. No doubt it has something to do with inadequate fiber in their diets. It is difficult to solve a problem when such self-administered email gurus are unwilling to consider they may have made an error.

If communications are the problem, keep it technical: get a free email account and use that to work around whatever problem exists.

**A Note on Copy Protection**

Professionally produced counterfeit or pirated software is widely available in some countries. However, the use of such software poses risks for the unwary, including the risk that the pirated software package is actually transmitting your location to police authorities. See the Beware of Counterfeit Software essay for a discussion of some of the little-known risks of using such software.

Some folks are outraged that a software company might utilize anti-piracy measures such as copy protection. Against the chance that some such people might be interested in the practical reasons why copy protection is employed, or that a sensible person may be called upon to calm down an angry colleague, we provide the following information:

With over 40% of the software in the US in commercial settings being used in violation of licenses and well over 95% of software in some countries being pirated copies, it's just not cost effective to create and offer software like Manifold at very low cost if copy protection methods are not employed. If you are very angry about that and disagree, that's OK: do not license Manifold software. There are always alternatives that may better fit your preferences for licensing, although none of them will have the extensive capabilities and ultimately lowest costs of Manifold.

For those folks who do choose to license Manifold, the license is not an unlimited one nor is it constructed to allow all possible users to run Manifold until the end of time no matter what happens. Providing that capability would be very expensive and would ruin the low cost that makes Manifold affordable to so many users. Instead, the license and copy protection mechanisms try to strike a balance that makes reasonable use possible at as low a cost as possible for as many users as possible. It's a formula that has brought real GIS capabilities to more users than ever before.

Experienced users will not get hung up on the idea of "buying" a license that will run "forever," as attempting to do that will simply raise costs in most cases. It's not even a realistic proposition, as people who attempt it usually discover.

Computer hardware and software technology change so rapidly that installations more than a few years old become antiques. They become difficult to keep running because replacement software and hardware parts are not available and because newer software requires newer technology. You know exactly what we mean if you've ever tried to find RAID drivers for that old box made in 2001 you are trying to press into service today as a web server running the most recent edition of Windows. As a practical matter the great majority of software versions should not be expected to have a lifetime of more than three to five years at the most.

Manifold issues new editions more frequently than that and provides a low cost upgrade path that makes it easy to get newer versions and additional activations for a modest fee. Some folks don't like the idea that to run Manifold "forever" they have to, in effect, "rent" a license by paying modest fees for upgrades every now and then. However, that is a necessary consequence of evolving systems: because Manifold is not freeware newer versions will not be free. The costs of creating new editions are very high and manifold.net is not willing to create such new editions without compensation. Likewise, the price we all pay for endemic software piracy is the limitation on usage and increased costs associated with copy protection mechanisms.

The current system is the least cost way manifold.net has found after years of experience to assure copy protection, to provide a low initial cost and to keep the costs of upgrades as low as possible. At the time of this writing, the manifold.net system has resulted in GIS software costs that are far lower than any other full-featured GIS software, in some cases over forty times less expensive than competitors. That's an amazing
accomplishment that could only have been financed by assuring, through copy protection using serial numbers and activations, that everyone has paid their fair share.

It's true that there will always be atypical cases where some users need more activations or some users might really intend to keep antique configurations running for many years. Sometimes that happens when people have unique usage patterns, such as using laptop computers in very harsh environments where the computers need to be replaced with unusual frequency no matter how careful the user may be. Such users will have higher costs and it is only fair that they should bear their own higher expenses for their special needs.

In other cases some people live disorderly, inattentive, unplanned lives and as a result will end up wasting activation keys. Some people acquire a Manifold license and then go on vacation for 30 days, so that when they return they no longer have a "free" period of 30 days before activation is required in which they can sort out any machine configuration problems. Some people don't bother to read even simplified instructions and so waste keys despite numerous warnings of lack of Administrator status or other admonitions. Some people don't bother to use anti-virus software or don't bother to familiarize themselves with Windows administration, so they find themselves unnecessarily burning through activations as they try to deal with the damage inflicted on machines by viruses or by imprudent machine management. Such people will encounter higher costs to license Manifold because they will have to acquire additional licenses to replace the activations they have wasted.

In most cases, even such unusual needs are not a problem because additional activations are so easy to get either for free or for very low costs. Between free yearly keys, very low cost additional keys and inexpensive keys from upgrades, it is really very difficult to run out of free or low cost keys. But some people have such extraordinarily unusual needs they might do so.

The least cost way manifold.net has found to service the above extraordinarily unusual needs, without forcing other users to bear the costs of those unusual needs or, in some cases, gross negligence, is to simply offer new licenses at the regular price. Of the many systems one can imagine to validate and deal with unusual situations that turns out to be the least costly method. The goal served by that method is to keep the cost of GIS as low as possible for as many people as possible.

Note: Users who want to run old machine configurations for many years should be aware that future editions of Manifold might not run on very old configurations, so if that is the intention it would be wise order a few extra Manifold licenses of the vintage of interest while such licenses are still available. We think a better idea is to simply get with the program and upgrade machine hardware, Windows systems and Manifold editions on a regular basis so that you are always working on the latest, super-cool new stuff the computer industry delivers. You don't have to upgrade every month, but trying to run antique hardware for 10 or 20 years is just not productive.

A related topic that may be useful in some cases, such as understanding what happens to a license if former partners squabble over a Manifold serial number when dissolving a partnership, is the Maintaining Your Manifold License topic.

Installing and Activating a Manifold Extension

This topic supplements the information in the Activation Keys and Serial Numbers topic. Please read that topic before continuing with this topic.

Installation

The Manifold System product line contains optional extensions, such as the Surface Tools and Geocoding Tools and Business Tools packages, which extend the functionality of Manifold by adding new commands and capabilities. These optional extensions are not delivered separately; instead, they are part of the code within every Manifold System installation and simply must be "unlocked" for functionality.

If you have licensed one or more of the three optional extensions you will receive a serial number that identifies the license for that extension. That serial number may be used to turn on that extension and to activate it for permanent use. The serial number and activation process used is similar to that used for Manifold System itself.

If you have licensed an extension, do not search for some special installation package or special setup program. If you have installed Manifold System you have already "installed" the code necessary for that extension. All you need do is use the serial number for that extension to activate the extension.

• If you have installed Manifold System you are ready to activate a Business Tools, Geocoding Tools or Surface Tools extension using the serial number for that extension that was sent to you.
• If you have not installed Manifold System you cannot activate or use an extension. Extension products require previous installation of Manifold System.
• If you do not have the serial number for the desired extension package, you will not be able to activate that extension.
• Serial numbers for extensions must match the release level of the Manifold System installation. For example, to activate Surface Tools on a Release 8.00 Manifold System installation you must have a 8.00 Surface Tools license.

Activating an Extension

The Help - Activate Extension dialog is used to provide a serial number and to activate a desired extension. When Help - Activate Extension is launched, the system will close any open projects and raise the Extension Activation dialog to allow entry of a serial number or of a serial number and an Activation key. The system will then shut down Manifold so that Manifold may be re-launched with fresh activation information. When Manifold is re-launched it will automatically be reconfigured so that the activated extension will be fully enabled.

There is no need to specify which extension is being activated, since each serial number for an extension is specific to the extension that it activates. For example, if you license the Surface Tools package from manifold.net you will receive a Surface Tools serial number. Entering that serial number into the Extension Activation dialog will automatically turn on Surface Tools.

Just like the serial number used to enable Manifold, serial numbers for extensions typically allow a temporary period of usage, normally 30 days, without requiring activation. This preliminary period allows time for users in remote areas to acquire an Activation key while still being able to use the extension. While an extension is operating on serial number alone the Help - About dialog will report how many days are left on that serial number before activation is required.

Note that some product bundles licensed by manifold.net may use a single serial number both for Manifold and also at the same time for any Manifold extensions. For example, the Universal Edition Manifold System product configuration provides a single serial number that turns on Enterprise Edition features and also turns on Business Tools, Geocoding Tools and Surface Tools features as well.

If you license a Manifold System edition other than Universal Edition and then also license Business Tools, Geocoding Tools and Surface Tools, you will receive four serial numbers: one for Manifold System and one for each extension. To install and activate all of these products you will have to use the Manifold System serial number to activate Manifold.

You will then have to use the serial number for each extension to activate that extension. You will end up going through the activation process four times, once for Manifold System and then once again for each of the two extensions. For this reason, licensing Universal Edition is a real convenience for managers and users because it allows use of a single activation procedure to install and activate Manifold System as well as all extensions.
**Example: Activating Geocoding Tools**

Activating a Business Tools or Surface Tools license uses exactly the same procedure as that given below using the Geocoding Tools extension as an example.

If you license the Geocoding Tools extension you will receive a serial number for your Geocoding Tools license by email. If you license more than one Manifold product in the same order all of the serial numbers for all the products in that order will be in a single email, clearly identified by product for each product licensed.

2. Launch Manifold System. Close any projects that may be open.
3. Choose Help - Activate Extension
4. In the Extension Activation dialog enter the Geocoding Tools serial number. Enter it exactly as it was issued to you by manifold.net. Do not change upper case to lower case. Do not replace hyphens with space characters or make any other changes to the serial number. If desired, you may also enter an Activation key for the serial number as well. Press Accept.
5. Manifold will then exit. When re-launched, the Geocoding Tools package will be enabled.
6. Using the serial number alone the Geocoding Tools package may be run for 30 days from the date the serial number was issued. After that, an Activation Key must be fetched and provided to the Help - Activate Extension dialog together with the serial number. Once an Activation Key and a serial number have been provided to the Help - Activate Extension dialog the extension will be permanently installed. Don't forget to login as Administrator when permanently activating the Geocoding Tools extension.

See the Activation Keys and Serial Numbers topic for information on how to get an Activation key. If your computer is attached to Internet you can get an Activation key automatically from the Extension Activation dialog by pressing the Get Activation Key via the Web button in the dialog. If your computer is not connected to Internet you can get an Activation key manually as discussed in the Activation Keys and Serial Numbers topic.

**Caution:** Just like your main Manifold System serial number, you only get five activations per serial number for an extension, so be just as careful with such activations as you would be with your Manifold System license.

**Command Line Activation**

Extensions may activated via a command line as set forth in the Activation Keys and Serial Numbers topic.

**Troubleshooting**

Visit the Support page on the manifold.net web site for links to the Activation Guide and Activation Troubleshooting pages.

The most common problems reported by users when activating extensions are:

- Administrator login not used. You must login as the Administrator in Windows 7, Windows Vista, XP, 2000, Server 2003 and Server 2008. See the Vista Admin Login link in the Support page if you think you are logged in as Administrator but in fact are not.
- Mixing up serial numbers. Except in the case of Universal Edition, you cannot use a main Manifold System serial number (such as a serial number for Manifold System Professional Edition) to turn on an extension. You must use the serial number for the extension. Likewise, you cannot use a serial number for an extension to turn on a main Manifold System license. For example, a Surface Tools serial number cannot be used to activate a main Manifold System Professional Edition license.
- Inaccurate system date. Your system date must be accurate to install an extension. The extension's serial number codes the date when it was issued and when it requires an Activation key and Manifold will not allow the serial number to be used if you attempt to use it outside the allowed dates.

Runtime Licenses

Manifold System licenses may be acquired as runtime licenses as an alternative to regular licenses. A runtime license provides all Manifold functions and capabilities except for those accessed through the console GUI (graphical user interface). Runtime licenses are used when deploying an IMS application to a web server or when deploying an application that calls Manifold capabilities programmatically through the API (applications program interface).

Note that regular licenses also provide console GUI functioning as well as IMS (Internet Map Server) and API capability. Therefore, when developing an application that calls Manifold one normally does so using a regular license since it provides both the console GUI and also IMS and API functionality. This gives the developer the ability to learn Manifold interactively using the console GUI as well as the ability to try out runtime functionality for an IMS or other application.

When the application has been developed and debugged and is ready to deploy, runtime licenses may be used to lower the cost of deployment.

The serial number provided when activating Manifold determines if Manifold will run in regular mode or in runtime mode. The serial number further identifies which Manifold capabilities are enabled. For example, providing a serial number for a Manifold Professional Edition Runtime license during activation will cause Manifold to subsequently execute only in runtime mode with Professional Edition features available either in IMS or otherwise through the API. Providing a Manifold Universal Edition Runtime serial number during activation will enable subsequent runtime use of Universal Edition features such as Business Tools features.

Once Manifold is activated using a runtime serial number then Manifold will execute only in runtime mode and no dialogs will be raised to remind the user when the initial 30 day period of installation for a serial number has expired. It is therefore wise to always activate a runtime license of Manifold using both a serial number and an Activation key so that when the initial 30 day installation period expires no one will be left wondering why it is that Manifold capabilities are no longer available on the machine. Attempting to launch Manifold interactively on a machine when a runtime license has been installed will display an error message.

Keep in mind when activating Manifold with a runtime serial number that once Manifold is so activated on a particular machine the runtime activation status will be remembered even if Manifold is subsequently uninstalled and then reinstalled. Thereafter, unless the activation status of Manifold is changed, Manifold will execute only in runtime mode. This means that changing the activation status from a runtime license to a non-runtime license will require using command line activation, since launching manifold.exe interactively will simply raise an error message.

Command Line Options
Manifold System License Server

All Manifold licenses are licensed and copy protected using one of two mechanisms:

- **Standalone licenses**, authorized using a Serial number and Activation keys that locks each license to a single computer system. This is similar to how Microsoft Word and other such applications are typically licensed. Manifold licenses acquired in small quantities or acquired for use on portable devices use this mechanism. If you have not acquired a Manifold System License Server product you should turn to the Activation Keys and Serial Numbers topic for a discussion of serial numbers and activation for your license.

- **Floating licenses**, authorized using a Manifold License Server. Manifold licenses acquired in larger quantities will frequently use this mechanism, which requires licensing of the Manifold System License Server product.

The rest of this topic discusses the Manifold System License Server.

**License Server Overview**

The **Manifold System License Server** product gives organizations the ability to maintain an inventory of floating Manifold licenses that may be used by any client computer that can connect to the License Server, all without needing to use serial numbers and Activation keys for individual client licenses.

License Server offers organizations several key benefits:

- **Fast and easy deployment** - IT managers can deploy Manifold using standard automated deployment tools with no need to individually activate each machine.
- **Security for license rights** - Serial numbers need not be handled at individual client machines, thus providing greater protection against theft of license rights. The master serial number authorizing License Server rights need not be shared outside the trusted group of IT managers.
- **Fewer licenses required** - Fewer licenses need be procured because only the maximum number of licenses that will be used at any given time need be acquired. Licenses need not be acquired for individual machines just against the chance that someone will need to use Manifold on that machine.
- **More efficient use of different Manifold editions** - License servers make it easy to have a range of Manifold editions available within the organization so that if a user normally works with Enterprise Edition but occasionally requires Universal Edition the higher edition can also be run. This reduces the number of higher end licenses that need be acquired if most users normally work with lower level licenses.
- **Simplified machine upgrades** - Because authorization is not stored on client machines it is not sensitive to upgrades in machine hardware or software. Client machines may be replaced, reconfigured or upgraded as much as desired without burning up a limited stock of client activations.
- **Reduced administrative overhead** - IT administrators need keep track of only one serial number per License Server no matter how many licenses have been acquired. That’s far easier than keeping track of individual serial numbers and activations per client machine.
- **Easier on End Users** - Personnel using Manifold on client machines don’t need to know anything about activation and can simply launch Manifold and get to work. End users cannot cause havoc on client machines by misusing activation commands from the Manifold menu.
- **Web service connectivity** - The Manifold License Server runs as an HTTP web service to which client machines connect for authentication. Most organizations have already configured internal firewalls and proxies to allow users to browse internal websites on their intranet or even to browse external websites on Internet. Running License Server as a web service, therefore, makes it likely that it will work “out of the box” in most organizations or, at worst, require only a few well understood, easy to apply and easy to test adjustments to proxy settings or network configuration.

While License Server is great, it does have some constraints on usage:

- **Costly for small installations** - Running a License Server installation requires acquisition of the Manifold System License Server product plus acquisition of the desired number of licenses. Because of the cost of a License Server product plus the cost of the desired licenses is greater than acquisition...
of small numbers of non-License Server licenses, individual users and very small organizations will usually not acquire License Server.

- **Local web server required** - A License Server requires a machine on your local, private network that can function as a local web server running Microsoft IIS to host the License Server and to authenticate floating licenses via your local, private network. This machine may be used for other purposes but cannot be used to run Manifold other than as a License Server. Only one License Server can be installed on each machine. Although License Server can be successfully used to authenticate floating licenses for Manifold installations on virtual machines, such installations involve many nuances and uncertainties arising from the virtualization software in use; therefore, they are not supported by manifold.net.

- **One edition per License Server** - A License Server can only host licenses for a single Manifold Edition. If we need to distribute floating licenses for both Enterprise Edition and Universal Edition within our organization, we will have to acquire and operate two License Servers, one to serve Enterprise Edition licenses and one to serve Universal Edition licenses. The two License Servers will require two machines.

- **Extensions via Universal Edition** - A Manifold License Server can be used to authenticate only main Manifold System licenses and not optional extensions. If we require an extension such as Business Tools, Geocoding Tools or Surface Tools we must run a License Server that serves Universal Edition licenses. Universal Edition includes all three extensions within the main Manifold System edition. Runtime licenses are not available as floating licenses in License Server.

- **Connection to License Server** - License Server supports use of floating licenses only on machines that can connect every few minutes to the License Server using a private network. Notebook computers and other machines that do not have network connectivity with the License Server must use regular, static licenses. Most organizations that employ License Server for desktop machines will also acquire a number of individually-licensed Manifold System licenses for users of portable computers.

- **IT / Manifold expertise required** - While the installation and management of License Server does not require any unusual expertise, it does require sufficient technical skills to set up a simple web page and to resolve any proxy, firewall or other network connectivity issues between client machines and the License Server. Administrators should also have solid Manifold experience with clear understanding of and experience in installation and activation of Manifold licenses.

- **Not a way to lend or lease licenses** - Using License Server does not allow you to bypass the lending or other restrictions in the Manifold EULA. License Server provides more convenient and economically efficient licensing within one organization - it is not a way to share, loan out or lease Manifold licenses between different organizations or different individuals.

**Acquisition**

To license Manifold System License Server, contact Manifold Sales at sales@manifold.net or by telephone. Acquisition requires licensing the License Server product and at the same time licensing the number of Manifold System licenses for the edition desired to be served by the License Server. See the manifold.net web site for detailed sales information for License Server.

**Delivery**

The Manifold System License Server is simply a Manifold System Edition like any other. Download the standard installation file from the Product Downloads and install it by installing Manifold System like any other edition. Like any other Manifold edition, License Server is configured to be License Server by the serial number that is provided to authenticate the License Server configuration. Using a License Server serial number in the Manifold Activation dialog will configure that installation to function as a License Server. Also, download the licenseservermisc.zip file from the Product Downloads page for the .asp files mentioned below.

Once Manifold has been configured by the serial number to run as a License Server it will no longer run as an interactive GIS nor will it provide IMS or be accessible via the Manifold API for GIS functioning. The configuration will only function as a non-interactive License Server that can be utilized exclusively through the web service created by installation (see below).

The serial number issued when License Server is acquired will encode the Manifold System edition supported by that License Server as well as the number of Manifold System licenses authorized by that server.

**Activation**

Read the Activation Keys and Serial Numbers topic for details on the Manifold System activation process. Each License Server installation will use that process to activate the License Server on the target server machine.
Administrators installing License Server are assumed to be experts who are completely familiar with the Manifold System activation process described in the above topic.

The activation process is just like that used for individual licenses with the following exceptions:

- **Server key required** - Ordinary licenses use a **Serial number** and a **System ID** to fetch an **Activation key**, which is then used in the Activation dialog along with the Serial number and System ID to activate the installation. In addition to those three keys the License Server activation process also uses a fourth key, the **Server key**, which is provided by the Manifold activation web site. This fourth key is required for an .ini initialization text file placed on the License Server machine.

- **Manual activation required** - Ordinary licenses can use the Activation dialog to fetch an Activation key through the web. License Server installations must use manual activation. The person activating the License Server installation must visit the Manifold activation web site and use the Serial number and System ID to fetch an Activation key and a Server key. When the Manifold activation web site gets a valid License Server serial number, it knows that a Server key must be provided in addition to an Activation key.

- **No 30 day initial period** - Manifold System editions other than License Server can run for 30 days from the date the serial number is issued before activation is required. License Server serial numbers do not have this 30 day initial period. Instead, a License Server requires permanent installation with both a serial number and an Activation key for functioning.

In a nutshell, the process of installing and activating a License Server installation is as follows:

- Install and launch Manifold on the server. This launches the Activation dialog, which displays a System ID.
- Copy the System ID from the Activation dialog.
- Visit the Manifold activation web site. Enter the System ID from the Activation dialog. Also enter your Serial number, copied from the serial number email sent for that License Server license. Use Copy and Paste at all times to avoid typos.
- The activation web site generates an Activation key and a Server key. Copy the Server key to a safe place, like a text file that is immediately saved, on the License Server machine. Copy the Activation key and the Serial number into the Activation dialog and press Accept.
- Create a Manifold.ini text file using the Server key as described below and place it in the Manifold installation folder on the License Server machine.
- Copy the LicenseServer.asp file from the licenseservermisc.zip download file into a folder in the C:\InetPub\wwwroot hierarchy on the License Server so it can be accessed as a web service. Make it a web application in IIS.

On client machines, there is no activation necessary. Simply install Manifold on each client machine and then place a Manifold.ini text file created as described below in the Manifold installation folder on each client machine.

Like all Manifold system serial numbers, a License Server serial number is good for five activations and five activations only. Take care not to waste activations as it may be costly to get additional activation should you run out. A License Server serial number is licensed for use on a single server machine. Do not install the same License Server serial number on more than one machine, as you may lose your license rights completely if the same serial number is used to enable operation of more than one License Server at the same time.

Like all Manifold keys, the Activation key and Server key issued by the Activation web page are fetched by the specific Serial number and System ID used to obtain them.

Unlike other serial numbers for other Manifold editions, a License Server serial number does not allow a period of preliminary installation using the serial number alone. Instead, License Server must always be permanently installed using both a serial number and an Activation key. This is a safety measure because License Server normally controls very many licenses, potentially many thousands of Manifold licenses, and so cannot be placed at risk of a sudden stop if a preliminary 30 day period of operation expires because the IT manager running the installation forgot to permanently activate the installation.

License Server administrators should therefore be familiar with Manifold hardware and software requirements as well as with Manifold activation. Choose a stable, reliable machine for your server that won't have to go through hardware reconfiguration changes and which otherwise fulfills the general requirements (see the main Manifold web site) for running Manifold software.
Upgrading

To increase the number of licenses authorized by a License Server, please see the sales information at the manifold.net website or contact Manifold Sales at sales@manifold.net. Increasing the number of licenses will be accomplished by trading in your existing License Server serial number and being issued a replacement serial number that encodes a greater number of licenses.

Once the new serial number is in hand, it can be used to upgrade the License Server installation following the instructions that will be provided by manifold.net. You will need to launch License Server again and provide a new serial number to the Activation dialog to increase the number of authorized licenses.

Note that since License Server is, in effect, a runtime installation, to get the activation dialog you will have to use command line activation. The easiest way of doing this is to supply an invalid serial number in a command line activation to force Manifold to pop open the Activation dialog. For example, using the command line switch:

```
manifold.exe /activate:dialog
```

...will pop open the Activation dialog since "dialog" is not a valid serial number. See the Command Line Options topic and the Activation Keys and Serial Numbers topic for details.

Very important: You can only increase the number of licenses authorized by a License Server if that License Server product is the current Manifold System product being offered. When new versions of Manifold are published, after a few months the old version is discontinued and is no longer available. License Server licensees who may want to increase their licenses should make sure to transition their License Server installation to any new version of Manifold System that may be published, for example, by taking advantage of any limited time discounted upgrade offers for transitions to the new version.

Installation

Manifold License server may be installed on Windows installations equipped with .NET Framework 2.0 and running Internet Information Services 5.1 or more recent IIS. The following examples use ordinary internet URLs to make it clear how URLs are used. Keep in mind that your License Server must be accessed through a private network and not placed on the open Internet.

To install Manifold License Server:

1. Log in using a user account with Administrator privileges.

2. Locate the serial number email that was sent to you with your License Server serial number. Open the email so that you can copy the serial number when it is needed.

3. Install Manifold System if not yet installed.

4. Launch Manifold. When Manifold is installed onto a new machine, the Activation dialog will pop up when Manifold is launched. If using an existing Manifold installation Manifold will launch in the usual way. In that case, choose the Help - Activate command to open the Activation dialog.

   - Note that the Activation dialog has a System ID box that is filled with a System ID value to be used when fetching the Activation key. The Activation dialog also has boxes for a Serial number and an Activation key.
   - Copy the serial number from the serial numbers email and paste it into the Serial number box in the Activation dialog.

5. Launch a web browser and go to the Manifold activation page at:

   http://www.manifold.net/activation

   - Copy the serial number from the serial numbers email and paste it into the Serial number box in the web page.
Activation and Licensing

- Copy the System ID from the Activation dialog and paste it into the System ID box in the web page.
- Click the Create Activation Key button on the web page to create an Activation key and a Server key. These keys are fetched by the Serial number and System ID provided.

6. Copy the Activation key from the web page into the Activation dialog. The Activation dialog will now have the Serial number, System ID, and Activation key boxes filled. Press Accept. Manifold will open a box complaining it cannot run in interactive mode. Press OK. This message box shows that the License Server activation has occurred, since License Server cannot run interactively but can only run as a web service.

7. Create a new text file with the following contents:

```
[Activation]
ServerKey=XXXB4E2F4-6BAE9A-D54DE1E061E99BC7FA6FC58C82B4765
```

Instead of the fake key shown above that begins with "XXX" use the Server key generated by the Manifold activation web page for your serial number and system ID. Use Copy and Paste to transfer the Server key from the web page into the text file to avoid typographical errors.

- Save the text file into the Manifold installation folder (by default, C:/Program Files/Manifold System) as Manifold.ini. This file tells the License Server what Server key to use when License Server starts.

8. Create a new web site by copying the LicenseServer.asp file found in the licenseservermisc.zip download file into a suitable folder within the C:/inetpub/wwwroot hierarchy. Be sure to configure the web site to be a web application in the IIS configuration console.

9. Create a new text file with the following contents:

```
[Activation]
ServerUrl=http://myserver.com/manifold/LicenseServer.asp
```

Replace the fake URL above with the actual URL for the LicenseServer.asp file.

Save the text file into a temporary folder as Manifold.ini. You will need to copy this Manifold.ini file into the Manifold installation folder (by default, C:/Program Files/Manifold System) on each client machine that will run Manifold and will seek license authentication from the License Server. This file tells client instances of Manifold how to contact the License Server for permission to run.

If client machines will be connecting to the license server machine via a web proxy, also include connection info within the Manifold.ini file that is deployed to client machines using the following template:

```
[Activation]
ServerUrl=http://myserver.com/manifold/LicenseServer.asp
Proxy=<proxy server address>
ProxyUser=<proxy server user name>
ProxyPassword=<proxy server password>
```

If desired, specify the timeout for web requests to the license server machine by adding the following entry to the Manifold.ini file:

```
RequestTimeout=<timeout in milliseconds>
```

Note: in the above template examples do not actually employ the "<>" characters, which are used in the above only to indicate information that is to be provided. For example, if we would like a 30 millisecond timeout we would use:

```
RequestTimeout=30
```
10. On each client machine that is to be served by the License Server, install Manifold System but do not yet launch it. Copy the Manifold.ini file created in the previous step into the Manifold installation folder (by default, C:/Program Files/Manifold System) on that machine. You can now launch Manifold and it will automatically use the information in the Manifold.ini file to connect to License Server and get permission to launch. If all the licenses are not in use, Manifold will launch in the normal way. If all licenses are in use or if the license server cannot be contacted, an error message will result.

**Operation**

**On the server:** When IIS runs the LicenseServer.asp page, the License Server first checks the Manifold.ini file for a valid Server key. The internal cryptographic engine uses that key to determine that License Server is indeed authorized to work on this machine to serve the authorized number of licenses of the authorized Manifold edition. It then proceeds to service client requests up to the authorized number of licenses.

**On the client:** When Manifold launches it checks to see if a Manifold.ini file is present in the Manifold installation folder. If so, it knows to connect to a License Server for license authentication and follows the URL given to ask for a license. Manifold accepts whatever license is authorized by the License Server URL.

You can test the operation of the License Server by launching Manifold on a client machine that you know has network connectivity to the License Server web service. Manifold should launch normally. Choose the Help - About dialog to see what Manifold Edition is reported in use and confirm it corresponds to the Manifold Edition authorized by the license server.

To see how many licenses are being served, use a small Licenseservercheck.asp file as discussed below.

**Client Connection Logic**

Client instances of Manifold configured to connect to a License Server send it their System ID during startup, which the server uses to distinguish different client instances from each other. The server tells each client system whether or not the instance is allowed to run. The identification of client instances by system IDs allows running any number of Manifold instances on the same client system, all served by a single license slot.

If a client instance fails to obtain permission to run from the License Server upon startup (due all available licenses being in use or the server being unreachable), it refuses to run. If a client instance successfully obtains permission to run, it will launch Manifold and will thereafter contact the License Server every 5 minutes to maintain its license slot. If the instance fails to contact the License Server for more than 15 minutes, the License Server will consider that instance to be abandoned and makes its license slot available for use by other instances.

If the original instance tries to contact the License Server after a disconnect of greater than 15 minutes, it will find its license slot used up and will try to acquire another license slot. If the license server does not have any other license slots available, the instance will suspend operation and will wait until one or more of the currently running instances of Manifold give up their license slots. During the wait, the instance will display a modal Execution Suspended dialog, which is by default configured to try reconnecting to the server automatically every minute.

**Troubleshooting**

Assuming IIS is running correctly and the LicenseServer.asp file has been installed as a web application within the C:\InetPub\wwwroot folder hierarchy, the usual problem is a network configuration (firewall, etc.) that prevents a client machine from connecting to the License Server.

An easy way to check this is to put a small index.htm file comprising a simple web page in the same folder as the LicenseServer.asp file and then to attempt to launch that web page from a browser on the client machine. For example, if trying

http://myserver.com/manifold/index.htm

in your browser can't get a web page connection then you know

http://myserver.com/manifold/LicenseServer.asp
won't work in Manifold.ini either.

Next, create a small .asp test file as described in the Create a Simple ASP File section of the troubleshooting IMS topic. That will verify that ASP is turned on in your web server as well.

Don’t forget to check the obvious:

- Is IIS running and web pages (see above) on the License Server can be accessed from client machines?
- Is Windows firewall or other software firewall, if used, configured to allow outbound web server HTTP connectivity?
- Is IP Filtering enabled for the network connection? If so, make sure port 80 is allowed to enable HTTP traffic.
- Are any hardware firewalls or port filters in place between the server and client? Make sure they are configured to pass HTTP.
- Is a proxy server used? If Manifold fails to launch and a proxy is in use, make sure the values of the ProxyXxx entries in the Manifold.ini file are correct and the value of the RequestTimeout entry, if used, is not too low.

See the Support page on the manifold.net website for any additional notes that may be published on License Server operation. Because License Server troubleshooting is almost always network debugging that has nothing to do with Manifold, technical support for License Server is handled using developer level support incidents.

Security

Administrators who work with License Server in large local area networks will often want to establish security measures to ensure that their floating licenses are not used up by unauthorized personnel. Security may also be required to ensure that use of License Server is kept within the licensed organization, a requirement of the Manifold license for License Server.

Because License Server is implemented as an HTML server it is easy to apply the usual security measures employed within Windows networks and IIS web sites to control access to a resource, in this case access to the HTML server that hosts License Server.

Two examples of such security measures include:

- **Proxy Server**: A proxy server could be set up on a bastion machine through which connections to the HTML server must pass. The password to access the proxy server could change from time to time to discourage unauthorized use.
- **VPN**: Even better, the HTML server could be on an intranet accessible only via VPN where credentialed access to the VPN is required.

Other general advice for security:

- Keep confidential the serial number for the license server.
- Maintain physical security on the license server machine.
- Maintain security between the license server and its clients (usually done with two-way authentication and some kind of encryption, as with a VPN).

Tech Tips

You can switch back and forth between local license authorization and License Server authorization on client machines.

When Manifold launches it first looks for a Manifold.ini file containing a ServerURL entry. If present, Manifold launches using the license authorized by the server cited in the Manifold.ini file. If no Manifold.ini file is present then Manifold checks for local activation status. You can use this startup logic to go back and forth between License Server authorization and local activation status by simply providing or removing a Manifold.ini file within the Manifold installation folder.
Suppose you install and activate Manifold Professional Edition using a Professional Edition serial number on a particular system, say, a laptop computer. If no Manifold.ini file appears in the Manifold installation folder Manifold will launch as Professional edition.

When the laptop is connected to the organizational network and can reach a License server, if you want to switch to using Enterprise Edition from a License Server you can copy a Manifold.ini file that points to the License Server into the Manifold installation folder. When Manifold launches it will see the Manifold.ini file and the ServerURL entry it contains and use that to launch as Enterprise Edition.

If you then remove that Manifold.ini file (or, as most people do, simply rename it to Manifold.txt or some other name), when Manifold launches it will not find a Manifold.ini and will launch Manifold using the local activation status as Professional Edition.

If you have several different Manifold License Servers available you can switch between authorized editions by simply changing the Manifold.ini file to point to whatever server you want. For example, if you have a License Server that authorizes Enterprise Edition licenses and another License Server that authorizes Professional Edition licenses you could keep two files in your Manifold installation folder, one called Manifold.ent and one called Manifold.pro, that contain the text for a Manifold.ini file that points to either an Enterprise edition License Server or a Professional edition License Server. Depending on which server you want to use you can copy either the Manifold.ent or the Manifold.pro file to the Manifold.ini file.

IT managers who want to automate the above can write a simple batch file that copies the desired ServerURL entry into a Manifold.ini file, allowing users to choose which Manifold edition they want to use when a selection of License Servers is available.

Checking the number of licenses in use is easy. Create a small page called Licenseservercheck.asp with the following code. Install the page on the machine hosting the License Server. Users can then navigate to that page from their clients to see how many licenses are currently being served. This page is provided in the licenseservermisc.zip download. The code is trivial:

```html
<%@ enablesessionstate=false language=javascript %>

Response.ContentType = "text/plain";
Response.Expires = 0;

// report current number of outstanding sessions
var svr = Server.CreateObject("Manifold.LicenseServer");
var res = "Current Sessions: " + svr.CurrentSessions; svr = null;

Response.Write(res);
%
```

Activation Keys and Serial Numbers
Maintaining Your Manifold License

Manifold System is licensed, not sold. That means your right to use Manifold System is subject to the terms and conditions set forth in the End-User License Agreement (EULA) to which you agreed when acquiring and installing the software. The license to use Manifold is not unlimited: there are significant limitations in the license, such as access to a limited number of activations and limitations on transfer that must be observed. Anyone who is in possession of a Manifold license has agreed to the terms and conditions set forth in the EULA. If you have not agreed to those terms and conditions, you are not licensed to use Manifold products.

In addition to the rights extended by the EULA manifold.net normally also voluntarily provides additional benefits to licensees, such as the opportunity to take advantage of certain discounted upgrade offers, sample usage of technical support products through two free standard technical support incidents, possible access to additional activation keys (either free or paid) and other benefits. Such benefits may be withdrawn or modified at any time without notice.

This topic explains in an informal way how manifold.net administers licenses so that you can take maximum advantage of your license. This topic does not replace or amend or alter in any way the EULA that sets forth the terms and conditions of your license. If there is any conflict in any way between this topic and the EULA, the EULA takes precedence and is the sole and complete authoritative statement of your license for Manifold System.

Routine Maintenance

By default, a Manifold product license requires no maintenance except retaining the original serial number email that issues the license and taking care to observe the terms and conditions of the EULA. For example, install the license on one computer and don't give out your serial number to other people.

There are no annual fees or compulsory support fees required. The default Manifold System standalone license is a fully paid-up license. Once installed on a computer it can run forever if that computer is not reconfigured in a way that destroys the activation of that license (significant disk changes, re-installation of Windows, etc.). Multiple activations are provided for each serial number so the license can be re-activated should significant reconfiguration occur on a computer or should the license be moved to a new computer. See the Activation Keys and Serial Numbers topic for details.

Very important: Direct support and free services from manifold.net are available only to the original licensee who is in possession of the original serial number email and is writing from the email address to which that serial number email message was sent. Manifold.net does not support third parties, such as customers of resellers who acquired a Manifold license from manifold.net and then provided that license to the reseller's customer. In such cases, the reseller must support his or her customers.

As is set forth in the EULA, it is OK to transfer your license to someone else; however, because manifold.net has no control over what is told to such a recipient or whether all Manifold materials provided to the original licensee have been provided to that recipient, manifold.net will not support that recipient with any free services. In general, manifold.net only provides free services, such as installation or activation support, to the original licensee.

Proof of License

As noted in the Activation Keys and Serial Numbers topic, a Manifold license is authorized by the specific serial number for that license. Anyone who has the serial number for a license can use that serial number to install the product and to get activations for that license. Conversely, anyone who does not have the serial number cannot utilize the license.

A Manifold license is controlled by possession of the serial number that authorizes that license. Licensees are identified by possession of the Manifold System serial number associated with the license. To comply with privacy regulations and other requirements, in any transaction with someone who claims to be a Manifold licensee manifold.net must know that the person is, in fact, the licensee.

The sole way a licensee can identify themselves is by producing the serial number for the license. If you do not have the serial number, you are not the licensee. If you lose your serial number, you have lost your license and, if you cannot use one of the optional key recovery services if such may be offered, you must procure another license to replace the one you lost. Further, any free services for activation or installation support from manifold.net are available only to the original licensee who is in possession of the original serial number email and is writing from the email address to which that serial number email was sent.
Lost Serial Numbers

Licensees want to have a functioning installation when they first install Manifold, so they usually pay reasonable attention to the installation instructions in the serial number email. Typical text used in serial number emails to advise users in the strongest possible terms not to lose serial numbers is as follows:

PLEASE SAVE YOUR SERIAL NUMBERS

DO NOT LOSE THESE SERIAL NUMBERS. IF YOU LOSE THESE SERIAL NUMBERS, THEY CANNOT BE RECOVERED.

If you lose these serial numbers, you will lose the ability to permanently install or to use the products they authorize, you will lose the ability to re-install your products or to move them to a new machine should you ever need to do so in the future and you will lose any ability to take advantage of future upgrade offers that require a Manifold serial number.

Do not expect that after using a serial number once you can safely lose it. Serial numbers are stored in Manifold products in encrypted form and cannot be recovered from the software installation: you will need these original serial numbers, so DO NOT LOSE THESE SERIAL NUMBERS.

PRINT OUT A COPY OF THIS EMAIL AND SAVE IT IN A SAFE PLACE.

Users who have installed their own Manifold licenses no doubt remember reading the above and have taken care to save their serial numbers. Likewise, most organizations likewise are careful to assign trustworthy individuals to manage valuable assets such as serial numbers. For example, an IT department that installs licenses on behalf of users will normally employ diligent employees who will take note of the above advice and who will make sure to save serial numbers in the IT department's records.

There are cases where a Manifold license has been acquired within an organization and information about the serial number, who ordered the procurement, how the license was obtained and how the license was utilized are hopelessly lost. For example, if Manifold was acquired by a person no longer employed by the organization then it could be the license has been irretrievably lost. In some cases organizations don't even know if they've acquired a Manifold license or if they have whether it was an employee's personal license, provided by a contractor or consultant, obtained through a reseller or through some other channel.

A Manifold serial number is like a prepaid telephone or cash card - if lost, it cannot normally be recovered. It is not tied to a particular user or machine or even a download. If you lose it, you should consider it gone. Under some circumstances for some types of licenses it might be possible, for a fee, for manifold.net to attempt to recover a serial number if the customer has detailed information regarding the original transaction. However, even in the best of circumstances such recovery may be unlikely. Therefore, optional key recovery service products to attempt a recovery might not be offered given the low chances of success. If offered, such optional key recovery service products will require a significant fee.

Key recovery services may be offered for a fee that have a good chance of recovering lost serial numbers if the information required for recovery exists. If your organization has lost your serial numbers and does not have enough information to use any optional key recovery services that may be offered, then your licenses have been irretrievably lost and you must acquire replacement licenses at the regular price. Replacement licenses are not discounted because it costs more to determine if a discount is warranted than the cost of fresh licenses.

Contacting manifold.net

For manifold.net to recognize you as a Manifold licensee when contacting the company on matters relating to your license you should include the serial number for your license. manifold.net will always take possession of the serial number as proof positive the correspondent is the licensee. Note however, that possession of a serial number does not entitle you to any services, such as tech support or other services, which are not part of the license. Such services are normally provided using support tokens or other mechanisms, some of which may be limited to the original licensee. Free services are provided only to the original licensee who is in possession of the original serial number email and is writing from the email address to which that serial number email was sent. See the Support pages on the manifold.net web site for additional information.

Running out of Activations
Manifold is not licensed for endless usage no matter how many times you need to re-install it. Each serial number can be used for only a limited number of activations. Through sensible use, prudent computer administration and by taking advantage of free additional keys, low cost additional keys or low-cost upgrades that may be offered from time to time it is fairly easy for virtually all users to continue using Manifold without running out of activations at a very low cost per year or at no cost at all. See the Activation Keys and Serial Numbers topic for details.

See also the Support pages on the manifold.net web site for any optional services (either free or paid) that may provide a route for additional activations for a serial number.

**Payment does not Confer a License**

The licensee is the person who has the serial number. That can be, and often is, a different person than the person who pays for the license. A very common situation is where one party is the credit card holder paying for the transaction while a different person is the user who receives the serial number email and who actually uses the product.

Occasionally in the course of disputes such as partnership dissolutions the person who paid for a license will be angry that manifold.net does not regard that person as a "co-licensee" or will not take instructions from him or her as the licensee. However, if you do not have the serial number you are not the licensee and you have no rights in the license at all even if it is you who paid for the license.

The situation is analogous to what happens if you buy a car for cash and then give it to someone else so the car is registered in that other person's name. As far as the car registry is concerned, if your name is not on the title to the car it doesn't matter that you paid for it. The person whose name is on the title is the owner of the car. Although car titles may be encumbered by lien holders, there is no such thing as an encumbrance on a Manifold license. Whoever has the serial number controls that license.

If you pay for a Manifold license, keep in mind that the user receiving the product and serial number will be the licensee. If you don't trust the licensee and wish to retain some degree of control over the license, provide your email address as the initial email address to which the serial number is sent. You can then forward the serial number to the ultimate user. However, in the meantime you can keep a copy of the serial number so that you too have physical possession of the serial number.

**Transferring a License**

The EULA allows you to transfer your license once to someone else. A license may only be transferred once, so the person to whom you transfer your license cannot subsequently transfer their license to someone else.

To transfer your license, provide the serial number to the new licensee. When transferring a license, you must also transfer all Manifold materials, such as product installation download files or serial numbers, to the new licensee. You must also delete Manifold System from any computer on which you have installed it, since if the same serial number is active on more than one computer a license violation sooner or later will be detected and the license will be revoked.

A transfer is a permanent change of licensee. You cannot lend a license to someone else by temporarily transferring your license to them and then having them transfer the license back to you. Once you transfer your license to someone else, you lose all rights in that license.

On occasion manifold.net will receive emails from people who say that a Manifold licensee has transferred their license to them and that manifold.net should update the license record accordingly and send them the required serial number. Such emails have no effect because only the licensee who possesses the serial number can transfer the serial number to a new licensee. If you think you have received a Manifold license from the original licensee but have not received the serial number for that license, you must take that up with the original licensee. If they have not provided you with the serial number for that license, you are not a Manifold licensee.

If you are acquiring a Manifold license from a third party, you must be able to trust that third party not to cheat you - it is a "buyer beware" situation. You must trust that the serial number provided to you is a valid serial number that matches the software provided and is the edition desired. For example, if you want to acquire an Enterprise license make sure that you are getting an Enterprise serial number and not a Professional serial number. You must trust that the serial number still has a sufficient number of activations remaining from the original five so that you can use the software as you desire. For example, if the serial number provided has only one activation left you will not be able to install Manifold both on a desktop machine and on a portable computer. Finally, you must trust that the person providing Manifold to you has indeed uninstalled Manifold from their computers and will not provide the serial number to anyone else, to be sure that your serial number will neither be revoked nor used up without your knowledge.
Activation and Support

Please make sure to read the Activation Keys and Serial Numbers topic carefully to understand the activation mechanism used to copy-protect Manifold before acquiring a license from any third party. To check the status of a serial number, please visit the Support page on the manifold.net web site for links to the status-checking page.

Very Important: Note that under no circumstances will manifold.net provide activation assistance for anyone but the original licensee writing from the original email address used for the license. If whoever procured the license you wish to use tells you otherwise, you are being misled.

Arguments between Partners

There are many circumstances in which the ownership of licenses may be in dispute. For example, partners who acquired Manifold for a mutual business may break up their partnership and subsequently argue over who gets the Manifold license. Partnerships are dissolved, couples divorce, businesses go bankrupt or are restructured, employees quit without making note of serial numbers, resellers might take money for Manifold licenses and not deliver the product and many other circumstances occur in which licensing rights become muddled in the eyes of participants.

In all such cases, manifold.net does not get involved in any private disputes. Under no circumstances will manifold.net intervene. Whoever has possession of the serial number controls the license. If more than one party knows the serial number and there is a dispute between those parties that is a problem between the parties which they must resolve on their own.

Disputes with Resellers

Manifold.net is a direct Internet sales company that does not designate resellers or authorize distributors. No person or company is authorized by manifold.net to in any way make any representations on behalf of manifold.net or to in any way act on behalf of manifold.net. No person or company is authorized by manifold.net to change the terms and conditions of licensing or any other business policy of manifold.net.

If you acquire a Manifold license from a reseller or other distributor, that reseller has simply acquired Manifold just as anyone else can do and has no special authorization from manifold.net to act in any way on behalf of manifold.net. If you deal with such a person you are engaged in a business deal that has no connection with manifold.net. If that person lied to you and told you they were an agent of manifold.net or otherwise specially "authorized" to represent manifold.net that is a problem between you and the person who lied to you.

The situation is just like that if you buy some used electronic equipment from a private seller on eBay. If that private seller lied to you about the nature of the equipment or neglected to give you various missing parts required to operate that equipment your dispute is with that private seller and not with the original manufacturer of the electronic equipment.

There are many consultants, VARs and resellers of various kinds in the GIS industry who are high-integrity people and who choose to use Manifold as part of the solution they offer. Such people can often be the source of outstanding value and service to customers, but customers must always be aware that in such cases they are dealing with a third party and not with manifold.net or any agent of manifold.net. Choose a reseller whose integrity you can rely upon.

Because the originating reseller is Manifold's customer, not the person who buys from the reseller, people who buy from that reseller must be able to trust the reseller not to cause that license to be revoked by financial or other cheats. For example, if the reseller procured a license using a credit card, resell the license to the reseller's customer and then a few months later the reseller charges back the credit card transaction that license will be revoked. Even if the chargeback is not successful (manifold.net disputes all chargebacks) the license will not be useable for future discount offers or for other transactions requiring the use of a credit card because it will have been permanently associated with an attempted credit card fraud.

Regrettably, a premium brand like Manifold will always attract the attentions of dishonest people who will falsely claim association with the brand in order to steal some of the brand's prestige for themselves. Just as some crooks will falsely claim to be "authorized" Rolex dealers when they are not, some people will claim to be "authorized" Manifold dealers when they are not. As always in business, customers should be wary of imposters and vendors of either counterfeit goods or counterfeit relationships.
In some cases the problem might not be outright fraud but just simple incompetence. Some middlemen are not able or willing to follow even the simplest of instructions or invest even the bare minimum of self-education but are nonetheless interested in using the booming market interest in Manifold to turn a quick dollar for themselves. Instead of facilitating software acquisition and installation such middlemen might cause chaos and frustration for their customers. Customers should not involve middlemen who do not have the expertise and willingness to support them and who do not bring true value added to the transaction.

Example 1

John Doe and Harry Doe are brothers working together in a partnership. John Doe orders Manifold System and receives the serial number. He gives the serial number to Harry. One year later the partnership dissolves acrimoniously and the partners verbally agree that Harry should get the Manifold license since he is the more technical person.

Harry Doe sends an email to manifold.net with the serial number for the license and directs manifold.net to change the license record to make Harry the licensee of record. manifold.net replies that whoever has possession of the serial number is the licensee and that the company does not update license records in that way.

A few weeks later, John Doe decides he doesn't like the verbal deal he made with Harry. Unknown to Harry, John emails manifold.net to get the serial number (he has mislaid it) and is informed that if he does not have the serial number, manifold.net cannot provide it to him.

John is upset, but when he cools down he sends all sorts of long letters and copies of partnership agreements to show that the partnership has dissolved and he, being the one who really paid for Manifold in the first place, should be the licensee of record. manifold.net politely replies that none of that matters as the company does not take sides in any dispute. Anyone with the serial number can control the license and someone who does not have the serial number is out of luck. The serial number is not tied to any user or any one machine. Anyone who has it can use it. Really.

After a while, John asks that if he finds his serial number can he order a transfer of the license back to him. manifold.net politely responds that whoever has the serial number as a practical matter can use it. John is not happy, but finally decides to honor the deal he made with his brother. He hires a new GIS guy for his new business and gets a fresh copy of Manifold.

Example 2

Jane Doe has acquired Manifold from a reseller who has assured her (falsely) that he is the exclusive Manifold authorized reseller in her geographic area. When she downloads and installs Manifold and launches the product, she discovers she needs a serial number. She calls her reseller who tells her to contact manifold.net to get a serial number.

For the sake of this example we don't know why the reseller tells Jane to contact manifold.net for the serial number. It could be that the reseller is dishonest and has already installed the serial number on the reseller's machine. Or, it could simply be that the reseller is negligent and hasn't bothered to pay attention to forwarding the serial number email to Jane.

Jane emails manifold.net requesting a serial number, providing a copy of her sales receipt from the reseller. manifold.net politely responds that Jane is not a Manifold licensee and thus manifold.net cannot discuss the status of any license with her. Jane is also advised to contact whoever provided Manifold to her to make sure that the original licensee transfers the license to her and also provides her with the serial number.

Jane becomes angry with manifold.net because she thinks the company owes her something since she acquired Manifold through an authorized reseller and so she writes a lengthy, angry email.

manifold.net politely responds that there is no such thing as an authorized Manifold reseller and no such thing as exclusive geographic territories and that if someone so represented themselves they did not tell her the truth. Jane is informed that manifold.net does not get involved in any dispute between her and any third party. The letter from manifold.net to Jane concludes by citing the manifold.net web pages that state for the record manifold.net does not authorize any agents or resellers.

In the above case, Jane's best recourse is to work the issue with the reseller, getting the reseller to give her the serial number for the license (which most likely was emailed to some email address provided by the reseller). Jane can then use the serial number as she sees fit.
Note that **manifold.net** is not at all involved in the above transaction since the company does **not** authorize any resellers or have any special contractual arrangements to allow any third party to represent the company. **manifold.net** is a direct Internet sales company and does not use distributors or resellers. However, anyone can purchase from the company and then subsequently resell and transfer a license to someone else as allowed by the EULA.

The situation is no different than if someone walks into a computer store, purchases a Microsoft product, and then later misrepresents himself to other people as an authorized Microsoft reseller, sells them the Microsoft product he bought in the store and fails to provide essential information required for use. In that case, Microsoft is not involved at all in that transaction since Microsoft has no control over what people do with the product once they buy it in a store, as anyone can do.

**Example 3**

Harry Doe goes to work for a large company as a temporary contract employee and suggests the company begin using Manifold System. He orders a copy of Manifold using a personal credit card (he is later reimbursed for the expense by the company) using his home address and gives a *hotmail.com* email address since he has not yet been issued a company email address. When the serial number email arrives he downloads and installs Manifold on a machine at work and begins using it.

A few months later the temporary project is completed and Harry is hired by another company. He carefully hands over his serial number email and other information to his replacement, explaining the need for the replacement not to lose the serial number and to review **manifold.net** tech support procedures and how to use the serial number. But the replacement is a new guy who is somewhat careless. He doesn't bother to review the information or save the serial number. A year later the computer on which Manifold was installed crashes and Manifold needs to be re-installed and re-activated, but no one can find the serial number for the license or even remember how the company came to be in possession of Manifold.

The company sends **manifold.net** an email explaining the circumstances, asking **manifold.net** to provide a list of all licenses acquired on behalf of the company and requesting a transfer of any licenses to a current employee. **manifold.net** politely replies that if the customer no longer has a serial number they may have an opportunity to use a key recovery service, for a fee, but otherwise any serial numbers are indeed lost.

In this case the company should have taken better care to manage its intellectual property assets, such as license rights, to avoid losing valuable assets during a change of personnel. The company's best option is to contact Harry and to ask him if he still has a copy of the serial number or if he remembers how the company came to possess a copy of Manifold.

Eventually, they find someone who remembers Harry and they send him a note asking him about the serial number. Unlike his careless replacement, Harry is a good guy and very organized and has kept a copy of the serial number exactly because he suspected his replacement would be negligent. He sends in the serial number.

However, suppose no one could remember how the company got Manifold or perhaps Harry was not a good guy or left the company under negative circumstances and thus was disinclined to do any favors for a company that no longer employs him. In that case the company probably has no practical recourse other than to pay for a new license or to take a chance using whatever key recovery service might be available.

**License Terminations**

If you do not follow the terms and conditions of the EULA **manifold.net** will revoke your license to use Manifold System. Licenses will also be revoked for non-payment. For example, if you chargeback a credit card transaction with **manifold.net** you will lose any Manifold licenses procured in that transaction and you will permanently lose any access to transactions requiring the use of a credit card, such as discounted upgrades to future products, even for any products you procured that were not involved in the chargeback.

Note that a Manifold System license cannot be loaned or shared, nor can it be installed on more than one machine except that in addition to installation on one desktop machine it may be installed on a portable computer used principally by you so long as that Manifold license on the portable machine is not used at the same time as the one on the desktop machine. In a nutshell, you cannot allow your Manifold license to be used on multiple machines. If you do, sooner or later the license violation will be discovered and your license will be revoked.

Do not lend to or share Manifold System with other parties. You may transfer your license on a one-time basis, but note that you must provide your serial number and all materials without retaining any functioning installations of Manifold System. If you acquire a Manifold license and then provide it to some third party without transferring
all use as required by the EULA, it is only a matter of time before manifold.net becomes aware that more than one person is using the same Manifold license, causing the license to be revoked.

Do not publish serial numbers or Activation keys or other tokens in any public forum. Doing so will revoke the license.

Summary

The bottom line is that it is very easy to keep your Manifold license in good shape: don't make illegal copies of Manifold, don't install one license on multiple machines, don't loan out or share your Manifold license and don't post your keys on the web. Make sure to save a copy of your original serial number email in a safe place. If you do decide to transfer your license to someone else, do not retain your original installation. You cannot continue running Manifold if you transfer your license to someone else. You must uninstall your original license, delete all Manifold materials in your possession and transfer both the serial number and all materials to the new licensee so both you and the recipient comply with the EULA.

If you acquire a Manifold license from someone else it is up to you to make sure the serial number you receive still retains sufficient activations for you to get the use you desire from that license.

Tech tip: You can check the status of any serial number by visiting the Serial Number Status page that is a link available in the Support page and in many other pages on the manifold.net web site. By entering a serial number into the Serial Number Status page you can see if it is a valid serial number, what Manifold edition it authorizes and how many activations have been used.

License
Activation Keys and Serial Numbers
1. **GRANT OF LICENSE.** This Section of the EULA describes Your general rights to install and use the Software Product. The license rights described in this Section are subject to all other terms and conditions of this EULA.

- **General License Grant to Install and Use Software Product.** For each serial number key issued to you by Manifold You may install and use one copy of the Software Product on a single computer, device, workstation, terminal, or other digital electronic or analog device ("Device"). You may make a second copy of the Software Product and install it on a portable Device for the exclusive use of the person who is the primary user of the first copy of the Software Product provided that the Software is not used on both Devices simultaneously. A license for the Software Product may not be shared.

- **Alternative License Grant for Storage/Network Use.** As an alternative to the rights granted in the previous section, You may install a copy of the Software Product on one storage Device, such as a network server, and allow individuals within Your business or enterprise to access and use the Software Product from other Devices over a private network, provided that You acquire and dedicate a license for the storage Device upon which the Software Product is installed and each separate Device from which the Software Product is accessed and used, except however that any usage of map server functions from a separate Device exclusively via an interactive Internet browser that is generally marketed and available to the public shall not require a separate license for each such separate Device. A license for the Software Product may not be used concurrently on different Devices.

- **General License Grant to Install and Use Subscription Product.** The following licensing terms apply to You instead of the license grants in the previous two paragraphs if You licensed a subscription-based Software Product (a "Subscription Product"). You may install one copy of the Subscription Product on a single Device and use the Subscription Product for the term of Your subscription. You may also exercise the additional license rights described in the paragraphs below, but only for the term of Your subscription. The initial subscription period begins on the date You first activate Your copy of the Subscription Product and ends three hundred and sixty five (365) days thereafter. You cannot use the Subscription Product after Your subscription expires unless You renew or extend Your subscription. By renewing or extending Your subscription, You will be entitled to continue using the Subscription Product for a specified period of time beyond the date when Your previous subscription would have otherwise ended. All the terms and conditions of this EULA will continue to apply to Your use of the Subscription Product during any subsequent renewal periods unless otherwise specified. After the expiration of Your subscription, You can continue to open, view and print any documents You created with the Subscription Product.

- **Additional License Grant for Data Sets.** The Software Product may include certain digital maps or digital cartographic data sets, other data sets, documents, photographs, clip art, animations, sounds, music and video clips (together "Data Sets"). If so, the following terms describe Your rights to the Data Sets:
  - Except as specified in the next Section, You may use, copy and modify the Data Sets and distribute copies of the Data Sets, along with Your modifications, as part of Your software product(s) and service(s), including Your web site(s).
  - You are not licensed to do any of the following:
2. DESCRIPTION OF OTHER RIGHTS AND LIMITATIONS.

- **Copy Protection.** The Software Product may include copy protection technology to prevent the unauthorized copying of the Software Product. By way of example and not limitation such copy protection technology may require original media for use of the Software Product on the Device, may require dongles or other hardware mechanisms, may require the use of key codes, may restrict the Software Product installation to a single Device, may detect via a network if this EULA is being violated, may require Administrator login privileges for installation or may limit the number of re-installations allowed. It is illegal to make unauthorized copies of the Software Product or to circumvent any copy protection technology included in the Software Product.

- **Authentication Keys.** For correct function, this Software Product may require a serial number key, product activation key or other authentication keys ("Authentication Keys"). Such keys may be limited in number to limit the number of installations possible or for other copy protection purposes. If You lose any Authentication Keys Manifold may charge You a fee to replace or re-issue lost Authentication Keys if, in Manifold's sole and exclusive choice, Manifold chooses to offer such replacement or re-issuance services to You. Any Authentication Keys or other identifying information authenticating this license are licensed, confidential information and may not under any circumstances be disclosed to any third party except pursuant to a permanent transfer of this Software Product. You agree to allow Software Product to communicate with authentication servers from time to time without notice to authenticate the validity of any Authentication Keys required by Software Product to function. You agree to keep any such Authentication Keys strictly confidential (including any serial number keys issued to You by Manifold).

- **Not for Resale Software.** If the Software Product is labeled "Not For Resale" or "NFR," then, notwithstanding other sections of this EULA, You use of the Software Product is limited to use for demonstration, test, or evaluation purposes and You may not resell, or otherwise transfer for value, the Software Product.

- **Limitations on Reverse Engineering, Decompilation, and Disassembly.** You may not reverse engineer, decompile, or disassemble the Software Product, except and only to the extent that such activity is expressly permitted by applicable law notwithstanding this limitation.

- **Separation of Component Parts.** The Software Product is licensed as a single product. Its component parts may not be separated for use on more than one Device unless expressly permitted by this EULA.

- **Trademarks.** This EULA does not grant You any rights in connection with any trademarks or service marks of Manifold. You agree not to infringe any trademarks or service marks of Manifold.

- **Preservation of Notices.** Any customization or configuration of Software Product by You must retain all Manifold notices setting forth trademarks, copyrights, Software Product origin, licensing information, contact information for Manifold, limitations on usage or references to any Manifold sites in at least as prominent a fashion as in the original configuration of Software Product.

- **No rental, leasing or commercial hosting.** You may not rent, lease, lend or provide commercial hosting services to third parties with the Software Product, except that commercial hosting services consisting of Internet publication of .map file projects using the map server embedded in the Software Product is permitted, provided that You acquire a license for Software Product for each server used for such hosting service.

- **Indemnification.** You agree to defend, indemnify, and hold harmless Manifold, its officers, directors, shareholders, parents, agents, contractors, affiliates, subsidiaries, joint ventures, licensors, owners and employees, from any and all damages, costs, claims, taxes, levies, losses, expenses, fees, attorneys fees, liabilities or any other costs or expenses of any kind, including payment of same by You, that in any way arise from or result from the acquisition, licensing, possession, transfer or use of Software Product by You.
3. UPGRADES.

- **Support Services.** Manifold may provide You with support services related to the Software Product ("Support Services"). Use of Support Services is governed by the Manifold policies and programs described in the user manual, in "online" documentation, or in other Manifold-provided materials. Any supplemental software code provided to You as part of the Support Services are considered part of the Software Product and subject to the terms and conditions of this EULA. You acknowledge and agree that Manifold may use technical information You provide to Manifold as part of the Support Services for its business purposes, including for product support and development. Manifold will not utilize such technical information in a form that personally identifies You.

- **Software Transfer.** Except as specified in this Section, the initial licensee of the Software Product may make a one-time permanent transfer of this EULA and Software Product only directly to an end user. This transfer must include all of the Software Product (including all component parts, the media and printed materials, any upgrades, any Authentication Keys, this EULA, and, if applicable, the Certificate of Authenticity). Such transfer may not be by way of consignment or any other indirect transfer. The transferee of such one-time transfer must agree to comply with the terms of this EULA, including the obligation not to further transfer this EULA and Software Product. Subscription products are non-transferable. No transfers are permitted for Academic Licenses.

- **Termination.** Without prejudice to any other rights, Manifold may terminate this EULA and/or order Software Product to cease functioning if You fail to comply with the terms and conditions of this EULA. This Software Product may automatically terminate this EULA and cease functioning if it detects a licensing violation such as, by way of example and not limitation, unauthorized simultaneous shared concurrent usage of this license on different computers. If this EULA is terminated by Manifold You must destroy all copies of the Software Product and all of its component parts.

4. INTELLECTUAL PROPERTY RIGHTS. All title and intellectual property rights in and to the Software Product (including but not limited to any trademarks or service marks, digital maps or digital cartographic data sets, data sets, documents, images, photographs, animations, video, audio, music, text, and "applets" incorporated into the Software Product), the accompanying printed materials, and any copies of the Software Product are owned by Manifold or its suppliers. All title and intellectual property rights in and to the content that is not contained in the Software Product, the accompanying printed materials, and any copies of the Software Product are owned by content owners and may be protected by applicable copyright or other intellectual property laws and treaties. This EULA grants You no rights to use such content. If this Software Product contains documentation that is provided in electronic form, you may print one copy of such electronic documentation. You may not copy the printed materials accompanying the Software Product. You agree not to infringe any intellectual property rights in and to the Software Product.

5. BACKUP COPY. After installation of one copy of the Software Product pursuant to this EULA, you may keep the original media on which the Software Product was provided by Manifold solely for backup or archival purposes. If the original media is required to use the Software Product on the Device, you may make one copy of the Software Product solely for backup or archival purposes. Except as expressly provided in this EULA, you may not otherwise make copies of the Software Product or the printed materials accompanying the Software Product.

6. U.S. GOVERNMENT LICENSE RIGHTS. All Software Product provided to the U.S. Government pursuant to solicitations issued on or after December 1, 1995 is provided with the commercial license rights and restrictions described elsewhere herein. Software Product is not licensed for provision to the U.S. Government pursuant to solicitations issued prior to December 1, 1995.

7. APPLICABLE LAW. You agree You have acquired the Software Product in Hong Kong at download servers located in Hong Kong regardless of any intermediaries, companies, personnel, clients, redistribution agents, facilities of any kind or intermediate communications channels of any kind that may have been used to connect to those servers in any way, to cache, mirror or transmit files in any way or to acquire installation files for the Software Product in any way. You agree this EULA is governed by the laws of Hong Kong. In respect of any dispute which may arise hereunder, you consent to the sole and exclusive jurisdiction of the courts sitting in Hong Kong. You agree the Software Product is not licensed for acquisition, transfer or use in any jurisdiction where this EULA is not valid.

8. EXPORT AND USE RESTRICTIONS. You agree the Software Product is not licensed for acquisition, transfer or use in any jurisdiction where in the event of litigation the substantially prevailing party is not automatically granted attorneys fees and costs, payable by the substantially non-prevailing party. You agree to possess, transfer and use Software Product only in jurisdictions where the possession, transfer and use of Software Product is permitted by law. You agree to comply with all applicable international and national laws that apply to
the Software Product, including export control regulations if applicable to you, as well as end-user, end-use and
destination restrictions issued by governments that have jurisdiction over You.

9. TRIAL EDITIONS. The provisions of this paragraph shall supercede the provisions of any other paragraph of
this EULA. If this Software Product was provided by Manifold explicitly labeled in the startup dialogs as a "Trial
Edition," this EULA is limited as set forth by Manifold in its transmission of Software Product to You, or as set forth
in the startup dialogs associated with Software Product. Any such limitations shall supercede any other provision
of this EULA. Such limitations may be (by way of example and not limitation) a limited period of authorized
operation commencing from the time of installation, a limited number of invocations of Software Product, some
limitation as to the number of features enabled or processing capacity, or any combination of these or other
limitations. You may NOT modify Software Product or operate Your computer system or Software Product in a
manner that defeats the limitations set forth with the Trial Edition. You may NOT remove any dialogs or other
information associated with Software Product that set forth such limitations. Trial Editions of Software Product
may NOT be copied and may NOT be transferred to any third party. If a limitation set forth with a Trial Edition
specifies a licensed period of authorized operation ("Trial Edition Period") that is less than the 90 day period
("Warranty Period") set forth in the Limited Warranty provisions of this EULA, then the Warranty Period shall be
reduced to the length of the Trial Edition Period.

10. NO FAIL-SAFE USES AUTHORIZED. The Software Product has been created using industry standard
personal computer software technology. Personal computer software technology is not fault tolerant and thus this
Software Product is not designed, manufactured, or intended for use or resale as on-line control equipment in
hazardous environments requiring fail-safe performance, such as (by way of example and not limitation) in the
operation of nuclear facilities, aircraft navigation or communication systems, air traffic control, direct life support
machines, or weapons systems, in which the failure of the personal computer technology employed in Software
Product could lead directly to death, personal injury, or severe physical or environmental damage.

11. LIMITED WARRANTY

- LIMITED WARRANTY. Manifold warrants that the Software Product will perform substantially in
accordance with the accompanying materials for a period of ninety (90) days from the date of receipt.
- If an implied warranty or condition is created by your state/jurisdiction and federal or state/provincial law
prohibits disclaimer of it, you also have an implied warranty or condition, BUT ONLY AS TO DEFECTS
DISCOVERED DURING THE PERIOD OF THIS LIMITED WARRANTY (NINETY DAYS). AS TO ANY
DEFECTS DISCOVERED AFTER THE NINETY (90) DAY PERIOD, THERE IS NO WARRANTY OR
CONDITION OF ANY KIND. Some states/jurisdictions do not allow limitations on how long an implied
warranty or condition lasts, so the above limitation may not apply to you.
- Any supplements or updates to the Software Product, including without limitation, any (if any) service
packs or hot fixes provided to you after the expiration of the ninety (90) day Limited Warranty period are
not covered by any warranty or condition, express, implied or statutory.
- LIMITATION ON REMEDIES; NO CONSEQUENTIAL OR OTHER DAMAGES. Your exclusive remedy
for any breach of this Limited Warranty is as set forth below. Except for any refund elected by Manifold,
YOU ARE NOT ENTITLED TO ANY DAMAGES, INCLUDING BUT NOT LIMITED TO
CONSEQUENTIAL DAMAGES, if the Software Product does not meet Manifold's Limited Warranty,
and, to the maximum extent allowed by applicable law, even if any remedy fails of its essential purpose.
The terms of Section 11 below ("Exclusion of Incidental, Consequential and Certain Other Damages")
are also incorporated into this Limited Warranty. Some states/jurisdictions do not allow the exclusion or
limitation of incidental or consequential damages, so the above limitation or exclusion may not apply to
you. This Limited Warranty gives you specific legal rights. You may have others which vary from
state/jurisdiction to state/jurisdiction.
- YOUR EXCLUSIVE REMEDY. Manifold's and its suppliers' entire liability and your exclusive remedy
shall be, at Manifold's option from time to time exercised subject to applicable law, (a) return of the price
paid (if any) for the Software Product, or (b) repair or replacement of the Software Product, that does
not meet this Limited Warranty and that is returned to Manifold with a copy of your receipt. You will
receive the remedy elected by Manifold without charge, except that you are responsible for any
expenses you may incur (e.g. cost of shipping the Software Product to Manifold). This Limited Warranty
void if failure of the Software Product has resulted from accident, abuse, misapplication, abnormal
use or a virus. Any replacement Software Product will be warranted for the remainder of the original
warranty period or thirty (30) days, whichever is longer.

12. DISCLAIMER OF WARRANTIES. The Limited Warranty that appears above is the only express warranty
made to you and is provided in lieu of any other express warranties (if any) created by any documentation or
packaging. Except for the Limited Warranty and to the maximum extent permitted by applicable law, Manifold and
its suppliers provide the Software Product and support services (if any) AS IS AND WITH ALL FAULTS, and
hereby disclaim all other warranties and conditions, either express, implied or statutory, including, but not limited to,
any (if any) implied warranties, duties or conditions of merchantability, of fitness for a particular purpose, of
accuracy or completeness of responses, of results, of workmanlike effort, of lack of viruses, and of lack of
negligence, all with regard to the Software Product, and the provision of or failure to provide support services.
ALSO, THERE IS NO WARRANTY OR CONDITION OF TITLE, QUIET ENJOYMENT, QUIET POSSESSION,
CORRESPONDENCE TO DESCRIPTION OR NON-INFRINGEMENT WITH REGARD TO THE SOFTWARE
PRODUCT.

13. EXCLUSION OF INCIDENTAL, CONSEQUENTIAL AND CERTAIN OTHER DAMAGES. TO THE
MAXIMUM EXTENT PERMITTED BY APPLICABLE LAW, IN NO EVENT SHALL MANIFOLD OR ITS
SUPPLIERS BE LIABLE FOR ANY SPECIAL, INCIDENTAL, INDIRECT, OR CONSEQUENTIAL DAMAGES
WHATSOEVER (INCLUDING, BUT NOT LIMITED TO, DAMAGES FOR LOSS OF PROFITS OR
CONFIDENTIAL OR OTHER INFORMATION, FOR BUSINESS INTERRUPTION, FOR PERSONAL INJURY,
FOR LOSS OF PRIVACY, FOR FAILURE TO MEET ANY DUTY INCLUDING OF GOOD FAITH OR OF
REASONABLE CARE, FOR NEGLIGENCE, AND FOR ANY OTHER PECUNIARY OR OTHER LOSS WHATSOEVER ARISING OUT OF OR IN ANY WAY RELATED TO THE USE OF OR INABILITY TO USE THE SOFTWARE PRODUCT, THE PROVISION OF OR FAILURE TO PROVIDE SUPPORT SERVICES, OR OTHERWISE UNDER OR IN CONNECTION WITH ANY PROVISION OF THIS EULA, EVEN IN THE EVENT OF THE FAULT, TORT (INCLUDING NEGLIGENCE), STRICT LIABILITY, BREACH OF CONTRACT OR BREACH OF WARRANTY OF MANIFOLD OR ANY SUPPLIER, AND EVEN IF MANIFOLD OR ANY SUPPLIER HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

14. LIMITATION OF LIABILITY AND REMEDIES. Notwithstanding any damages that you might incur for any reason whatsoever (including, without limitation, all damages referenced above and all direct or general damages), the entire liability of Manifold and any of its suppliers under any provision of this EULA and your exclusive remedy for all of the foregoing (except for any remedy of repair or replacement elected by Manifold with respect to any breach of the Limited Warranty) shall be limited to the greater of the amount actually paid by you for the SOFTWARE Product or U.S.$5.00. The foregoing limitations, exclusions and disclaimers (including Sections 11, 12 and 13 above) shall apply to the maximum extent permitted by applicable law, even if any remedy fails its essential purpose.

15. ENTIRE AGREEMENT. This EULA (including any addendum or amendment to this EULA which is included with the Software Product) is the entire agreement between you and Manifold relating to the Software Product and the support services (if any) and they supersede all prior or contemporaneous oral or written communications, proposals and representations with respect to the Software Product or any other subject matter covered by this EULA. To the extent the terms of any Manifold policies or programs for support services conflict with the terms of this EULA, the terms of this EULA shall control.
Appendices

Appendices provide information on miscellaneous business, technical and corporate topics.

- **Units**: Units of measure available in Manifold.
- **Essays**: A series of essays designed to arm Manifold advocates with technological savvy with which they can win friends and influence people.
- **Help Links**: A laundry list of topics designed to catch people searching for traditional GIS notions in the index, so they can find the analogous Manifold topics.
- **Info**: Administrative, legal, sales and other information. A mix of boring, necessary and even some very interesting details, beginning with the Limitations topic.

## Tables

### Units

#### Unit Abbreviations

The following are unit abbreviations used with distance and area measurement functions in queries and scripts. In addition to these units, one can also use custom units supplied by the user as set forth in the Custom Units of Measure topic.

Boris Nikolaevich Delone  Transform - Triangulation
Lejeune Dirichlet  Transform - Voronoi Operators
Leonhard Euler  About Networks
Pierre Simon Laplace  Transform - Laplace
Johan Heinrich Lambert  Lambert Azimuthal Equal Area
Gerardus Mercator  Mercator
John Parr Snyder  Space Oblique Mercator
Georgi Voronoi  Transform - Voronoi Operators
User Interface Design

One of our favorite comments about Manifold System is a newsgroup posting that stated “Manifold is software for grown-ups.” A key aspect of growing up is realizing that good things require some effort. It is not at all grown up to expect that one can master a complex subject in three days. Part of growing up is realizing that study and practice are required to gain true expertise.

Manifold's user interface has been designed for the user who will be working with Manifold on a regular basis and who is willing to invest some time in mastering the system. It assumes the user will read this documentation and will learn enough about the different tools and the connections between them to choose that sequence of commands that does what the user wants.

The interface depends on the interplay of several different capabilities applied in parallel as needed by an informed user. For example, once we open a map window we will also open different panes and toolbars to do what is needed in the map. We might have a table window open and perhaps even have a drawing or image window open to work with one of the components that is a layer in the map. To accomplish various steps in our plan we click on different panes and windows and invoke different commands as needed.

This is a very different approach to user interface design than is used in “wizard” interfaces where everything proceeds step-by-step through a fixed, linear path. Wizard interfaces are fine for highly predictable, fixed tasks that use data in known arrangements. They are not at all good when a flexible approach is required.

The Manifold user interface involves use of several panes and toolbars surrounding one or more windows. It is a non-linear interface where the user sets up an activity and then chooses tools and modifies tool options during the activity. This is more difficult to learn initially but very fast and flexible for serious work.

If you have any comments or suggestions for improving the user interface, please send them to manifold.net using the process outlined in the Contacting manifold.net topic.

The Postmodern Interface

Manifold System 5.00 introduced the Manifold “postmodern” user interface, which is continued in subsequent editions. Previous editions of Manifold were similar to many ’90’s GIS systems in that they used lots of dialogs and lots of toolbar buttons. Manifold tries to minimize the number of special-purpose dialogs by relying upon global Windows ideas like Copy and Paste As and context menus to provide an upper level of command functioning. Instead of being called from lots of specific menus, dialogs involved in many operations will appear as necessary when various upper level command actions (copy, paste, context menu choices, etc.) are taken.

The postmodern interface philosophy believes it is better to use already-known, standard Windows moves in an implied way than to design explicit, special purpose procedures that must be learned. This reduces what must be learned that is unique to Manifold even as it expands possibilities. It also moves attention onto the objective of activities rather than onto memorizing the specific steps required for processing.

"Quiet Cockpit" Design

The Manifold user interface introduced "quiet cockpit" philosophy to GIS. The phrase “quiet cockpit” arises from modern human interface design for complex aircraft. The modern theory of cockpit design states that pilots should be able to focus their attention on important tasks without the distraction of numerous dials and controls flashing lights at them to announce that all is normal. In this view, a normal indication should be signaled by no signal. For example, a fuel gauge should not flash a green light to indicate there is a normal status of fuel. It should remain quiet unless fuel runs low, in which case it flashes red or some other caution color.

Manifold attempts to bring a quiet cockpit to GIS by enabling only those controls that can actually be used in the current situation. The main method is to change toolbar buttons so that only those that can be applied in the current context are visible and enabled. All other commands are hidden or disabled. Before one becomes familiar with the different tools this may seem unsettling as toolbars change when the focus is on different types of windows. After some experience one appreciates how always the right assortment of tools is at hand.

A Note for ESRI or MapInfo Users

As mentioned in the For Experienced GIS Users topic in the introduction, Manifold’s user interface is not at all like those used in older GIS products. Instead, Manifold's nomenclature and commands are based on a combination of several stylistic approaches:
Microsoft methods and terminology wherever a Manifold capability matches something within the Microsoft spectrum of products. For example, Manifold uses "Tools - Options" because that's where user preferences are kept within most Microsoft products.

- Microsoft Visual Studio, Visual C++ and Visual Basic user interface style for development and programming.
- Adobe PhotoShop concepts for photographic/artistic image editing.
- Manifold System logic and mathematics for GIS.

The manifold.net team is often asked why we did not simply clone ESRI methods and interfaces in GIS, since ESRI dominates GIS markets. There are three reasons why:

- The potential user base for GIS is far larger than the current ESRI population, which is a very small number by mass-market Microsoft standards. Making Manifold accessible to hundreds of millions of Microsoft Office users means adopting Microsoft terminology and methods, not ESRI's.
- Older GIS systems were created in a technologically less sophisticated time. Providing the full range of modern capabilities means adopting modern ways.
- We seriously intend to deliver a fusion of GIS, CAD, advanced database, image processing, photo editing, mathematics modeling and many other disciplines. The right user interface that works with a blend of such intense functions is a new user interface that blends the best ideas from all these disciplines and not just GIS.

We realize that the above approach make transitioning to Manifold more difficult for experienced GIS people who have a lot of ESRI or MapInfo experience they would like to leverage. However, for many ESRI or MapInfo users a transition to Manifold is really their first transition into the bigger world of Microsoft standards and mass-market PC software standards. For any professional person using computers this is a necessary step and not wasted effort. If you are not yet a Windows power user, we have written a Windows topic to help you power up.

Terminology in GIS

It's no secret that certain technical disciplines use pretentious words in a way that confuses newcomers. The traditional GIS community is guilty of this sin in a big-time way by employing an archaic and misleading vocabulary.

Technology in general and GIS in particular are difficult enough without making things any more difficult by using artificially obscure language. Everyone who is a friend of GIS should work hard to promote a clear, modern and easily understandable lexicon. There are over one hundred million computer users in the world working at a sophisticated enough level to be able to use GIS. Clear language (as well as mass market value and pricing) will help them use GIS.

Manifold tries to help by using Microsoft terminology to refer to points, lines and areas. This is what most of the world's mathematics and computer community uses. ESRI and ESRI imitators within GIS use different terms:

<table>
<thead>
<tr>
<th>Manifold</th>
<th>ESRI</th>
</tr>
</thead>
<tbody>
<tr>
<td>Areas</td>
<td>Polygons</td>
</tr>
<tr>
<td>Lines</td>
<td>Arcs</td>
</tr>
<tr>
<td>Points</td>
<td>Points</td>
</tr>
</tbody>
</table>

Using the Word "Arc" is Misleading

Over one hundred million intelligent and sophisticated computer users are confused by the use of the word "arc" to mean a line. It's really misleading to use such terminology unless one is trying to discourage new users from getting into GIS. It is even mathematically illiterate.

The overwhelming usage by English-speaking, mathematically expert persons throughout the world is to use the word "arc" to mean a segment of a circle. Only a tiny handful of mathematically literate users understand "arc" to also mean a link between vertices in a graph. From a purely mathematical point of view it is foolish and pretentious to the point of being offensive to use this word in a geometric context to mean something other than a segment of a circle.

It is true that "arc" can mean a link between vertices in a graph (from which meaning ESRI apparently derived its use of this word). However, contemporary graph theory literature written in English uses the word "edge" nearly universally instead of "arc." The ESRI usage therefore is becoming ever more obscure even among professional mathematicians working in graph theory. When you hear the word "arc" in arc-speak, think "archaic".

A further effect is that much literature on "graph theory" in English now is really applied mathematics focusing on computer networks. As a result the terminology of computer networking dominates technical usage. Most people now use the computer networking word, "link." Even the word "graph" is now being replaced by the more modern word "network" when the great mass of literature is considered.

Regarding mathematical illiteracy: those relatively few people who understand graph theory are careful not to toss words like "arc" about inaccurately. It's those folks who have the weakest understanding of graph theory who leap to use this word in wrong contexts. From a mathematical perspective, only a very small percentage (likely less than one percent) of those vector objects called "arcs" within the ESRI community are really arcs. All the rest are simply lines.

A network is defined by its nodes and not by lines. The most common error of graph theory newbies is to draw a system of lines that have coincident ends and then say, "there, that's my network." Nope. If it does not have any points it is not a network. One point by itself can be a network. Two points by themselves is a disconnected network. Two points with a link between them is a connected network. Any number of lines without points is not a network even if they are arranged in a pretty diagram. Even within archaic graph theory nomenclature a line is not an arc unless it has a node at each end.

Since the vast majority of GIS data that uses line objects consists of lines drawn for purely illustrative purposes without points it is mathematically illiterate to refer to such objects in a general way as arcs. Even those few GIS data sets in which lines have points at the ends of them are not often graphs in a consistent way. Anyone who has ever had to do graph theoretic transportation analysis knows how few "clean" data sets exist in which the lines are really arcs.
Manifold avoids misusing the language of graph theory by simply referring to lines as "lines." When discussion revolves around graph theoretic concepts and operations, Manifold follows accepted modern network terminology so that the English language versions of Manifold use the word "network" instead of "graph," "nodes" instead of "vertices" and "links" to mean the connections between nodes in a network.

We realize there are many users within the ESRI community who know perfectly well what arcs are and are not in a precise mathematical way and who nonetheless choose to use this word as a matter of familiar ESRI jargon. That's OK as long as we are all careful to make it easy on newcomers by using more accepted words.

**Dump "Polygons"**

At least those things referred to as "polygons" in ESRI-speak are in fact polygons from a strict mathematical perspective. However, they are almost never regular polygons nor are recognizable as figures composed of straight-line segments. This is an important distinction to make if we are interested in advancing GIS within the general population of computer users. As regards geometric awareness, that general population can be divided into two classes: the mathematically illiterate and those who have some mathematical literacy.

Among the masses of tens or hundreds of millions of people who could potentially use GIS most have little or no awareness of mathematics and geometry. Such people have no idea what a "polygon" is and are somewhat put off by the term. However, everyone educated enough to use a GIS knows what a "region" or "area" is. Among those who have had some education in math most people understand a "polygon" to mean a regular polygon such as a pentagon or as a figure that obviously consists of a series of straight line segments. What they see in GIS contexts (curvy regions) look nothing like the "polygons" they recall from geometry class. Using the word "polygon" to describe things that do not look like polygons will unfairly confuse new users.

For this reason, a word like "region" or "area" is a better idea than using the word "polygon." Manifold uses the word *area* because this word emphasizes the inner content of such objects as opposed to the wireframe nature of regions delimited by boundary lines. We do not use the word "shape" because in the Microsoft world this word has a pre-existing meaning that is somewhat mixed between the idea of a vector object like an area and a raster region of differently-colored regions. We try to use the word *region* to refer to distinguishable subsets of pixels in images.

**Elementary Errors in Networking Terms**

There are two elementary conceptual errors within some traditional GIS packages that show up in misuse of terminology:

- Using the word *node* to refer to an internal coordinate that defines a polyline instead of a vertex in a network.
- Not realizing that a network is defined by its nodes and not by its links.

The above are dreadfully illiterate from a network math perspective and are among the errors that lead to university geography departments being treated in a patronizing way by their colleagues in the mathematics faculties. Friends of GIS should take care to use mathematical terms accurately to preserve respect for our profession. Manifold tries to help by using such terms rigorously.

Manifold can treat any system of lines and points as a network. When we discuss network subjects within Manifold, we shift terminology so that points are called *nodes* and lines are called *links*. We use the word *node* to describe points that participate in a network because universal usage within computer networking and graph theory reserves the word *node* to mean a point that acts as a vertex of a network.

People unfamiliar with networks will often refer to a system of lines such as that in the first illustration below as a "network." However, a network is defined by its *nodes*, not by its links. Links are simply a way of describing how the nodes of a network are formed into a network. If a drawing (or map) has no points, it is not a network.
Suppose we have three lines that are incident to each other at a location. This system of lines is not a network, since a network is defined by its nodes (points) and the above illustration has no points. If we would like to treat these three lines as a network we need to create a point at the ends of the lines.

We can use the Node Points transform to create a point at the end of each line. Only one point is created at the location where all three lines are incident to each other.

Note the difference between the Add Node Points and the Points transform:

Had we run the Points transform on the initial drawing we would have obtained the result above. The Points transform adds points at every coordinate location that defines the shape of the lines. The resultant points appear at what some legacy packages refer to as "nodes." At times one encounters traditional GIS software that also refers to such coordinate locations as "vertices." However that is even more illiterate than the wrong use of "nodes" since the term vertex is a very accurate, very well defined term from graph theory that very definitely means the same as node in a networking context. It very definitely does not mean the same as "inflection point" or "coordinate location in a polyline."

**Modernize the Rest as Well**

Let's face it: weird words like "coverages" mean something to someone who has been immersed in arc-stuff for the last few decades but they don't mean anything to anyone else who uses computers. There are plenty of unpretentious, good words in common usage that everyone will immediately understand that could be used instead of strange words like "coverage." Manifold uses the term drawing since that is the word almost universally used for such things by vector editors in the graphics arts and CAD worlds. Such users outnumber GIS users by about a thousand to one so it seems wise to adopt their terminology as the standard in modern computing.

In general, whenever the great big world of computing in general has a good word that is universally used Manifold tries to use it within GIS as well. At times there are no common words in use in computing but there are good English words that describe GIS things in a more accessible fashion than words used by the GIS community. If they are truly obvious words they will not confuse GIS experts while making life easier for newcomers. A few words used within Manifold are experiments that we hope will make GIS more accessible without losing any technical meaning.

An example of these is our use of the word tracing to describe vectorization. We think it is a natural word that people immediately understand that will help take the mystery out of "vectorization." It describes the process very clearly as well. Everyone understands the idea of laying a sheet of tracing paper onto a photograph and then drawing lines with a pencil to outline what is seen in the photo. The "raster" photo then becomes a "vector" line drawing.
From a purely mathematical perspective almost none of the objects in GIS drawings are really "vectors" anyway so there is no harm done in replacing this jargon with a more accessible word like "tracing". Check out the Tracing topic to see if you agree.
Images can be Inefficient

Most of the visual impressions we see published on the web and in print media are images. See the Images topic to understand the structure of images.

Images consist of a sea of pixels that are distinguished from each other only by the color of the pixel. Unlike drawings, there are no "objects" in images. Any objects we see in images are really illusions in the human mind. When we see a cloud of pixels that appears to be a line from far away, the appearance of the line is an interpolation created within the human eye and brain physiology… there's no "line" actually there.

Newcomers to GIS are often seduced into using images inappropriately for a variety of reasons:

- Images are easy to create by scanning photographs or paper maps.
- When scanned from paper maps, images can have a very rich visual appearance.
- Creating new drawings with high detail is a tedious and time-consuming process.
- Formatting drawings to provide a rich visual appearance is very time consuming and requires good taste and expertise.

However, one can pay a high price for using images inappropriately within GIS. There are many circumstances where using images is the right thing to do and there are times when using images is a very bad idea. One must be aware of the benefits and costs of using images. In particular, using images as a replacement for vector drawings is rarely a good idea. Using images for photographs, scanned data samples and other continuously varying, analog data representations is fine.

Since the usual problem is inappropriate use of images, the following sections focus on the downside of using images.

Large Size / Low Information Content

When used to replace vector drawings, images can be unacceptably large for the amount of information they contain. Let's see how by doing a thought experiment. Suppose we have a room with a large, smooth floor like a basketball court and we want to draw a line on the floor that shows an outline of Europe. We could proceed in at least two ways.

One way to draw the line would be to place thumbtacks at places marking the outline and to then stretch a ribbon or string between the thumbtacks to mark the outline in a "connect the dots" fashion. This method is analogous to how a drawing works in that the only data necessary to keep on hand are the coordinates that mark the shape of the outline.

Another way would be to cover the entire surface of the floor with small, flat pebbles. We would use white pebbles throughout the entire floor except for those places where we wanted to mark the outline of Europe. To mark the outline, we could carefully replace some white pebbles with black pebbles. If we placed the black pebbles carefully, we could view the floor from an elevated location and see the outline of Europe in the pattern of black pebbles winding its way through a sea of white pebbles. This method is analogous to how an image works. The pebbles are the same as pixels.

It takes no special genius in computer software design to consider the above situation and realize that marking a line on the floor using a ribbon to connect the essential locations that define the shape of Europe is a lot faster and more efficient than placing millions of pebbles on the floor. It is also less wasteful of resources. In the case of using pebbles, most of the "pixels" placed on the floor are not necessary. They simply provide a sea of white against which the black pebbles become visible to our eye as a pattern that we see as the shape of Europe.

Note also that in the first case we have a true object, the ribbon, which makes up the outline of Europe. In the second case there is no object, just a visual effect we reckon to be an outline by virtue of contrasting color.

Suppose we had a computer file that told us where to place thumbtacks in the first method and we also had a computer file that listed all the locations and color for each pebble in the second method. The file for the first method would have to list only the number of coordinate locations needed to define the shape of Europe, perhaps as few as a few thousand numbers. With the pebbles, though, whether or not the pebble participates in showing the actual shape of Europe, each pebble location and color must be noted. The computer file for the second method would therefore use millions of numbers to contain the same information as the "drawing" file.
The situation in GIS is very similar. A drawing showing urban streets in high detail might be only five megabytes in size. An image showing the same streets as a raster could easily be 125 megabytes in size. Although images can be compressed to eliminate some of their waste, it seems unreasonable to first choose a highly inefficient method and then spend a lot of time trying to make it somewhat more efficient. Compression also does not eliminate the need to manage pixels in uncompressed form when the images are actually used within a GIS.

There are cases, of course, where images can be an efficient way of presenting data in terms of the amount of information captured for a given size of file. The obvious case is photographic images. Suppose the floor of our hypothetical basketball court was covered with an enlarged photographic image of a region shot from space. Each "pebble" or pixel could be the right color to form an overall photographic image. To capture the same image using a drawing would not gain any efficiency since the drawing would have to contain at least as many points as pixels in the image.

In another example, suppose we wanted to present a detailed pattern of data such as minute variations in temperature or reflectance over our basketball floor. In that case, a vector drawing representation would have to put points at every location we wished to note together with a measurement. There would be as many vector points as there would be "pebbles." In this case as well an image makes sense. In general, where data represented is analog or continuously varying in nature images are a good choice.

**Low Accuracy**

To consider our example of two ways of drawing an outline of Europe, it's clear that using the drawing approach provides precise accuracy for the position of every thumbtack marking the outline and the ribbon or string that passes between it. In contrast, when marking the outline of Europe with black pebbles placed within a sea of white pebbles we will inevitably confront "the jaggies" where the pattern of black pebbles stair-steps between pebble locations.

No matter how far we zoom into a vector drawing the accuracy of the shapes drawn between coordinates is perfect. A line drawn between various coordinates will always be perfectly razor-sharp at any zoom level.

With images, in contrast, we can always zoom into the image to the point that pixels appear as large square shapes. At that point, it is not exactly clear where lines may be located. We may think we can interpolate by eye but that will not work if we zoom even further into the image. Images are therefore "accurate" only if they are seen from far enough away that our eye doesn't see the inaccuracy of the image.

A further point of inaccuracy is that most images representing vector maps are derived from paper maps, which in turn were created by human, subjective interpolation of vector data. For example, terrain elevations are usually measured at specific points. When those points are marked out and joined by contours, the contour drawing is inevitably a process of interpolation. When maps are printed, they are further interpolated into the pattern of small dots used in the printing process.

To convert a printed map into a digital image, the printed map is interpolated yet again when it is scanned. The result is a highly irregular pattern of pixels like that seen above (taken from a USGS digital image of a scanned paper map) that represents several levels of interpolation from whatever original data was used to create the map.

**Limited Data Content**

Drawings can contain arbitrarily rich data for each object. In a drawing, each object is connected to a record in a database table. That table can contain many fields of very rich data types, and the table can be linked to other tables via relations. Drawings can therefore act like visual windows into a database. The database can also act as an algorithmic window into the drawing since objects in drawings can be selected using SQL and other database methods.

Images, in contrast, can contain no data other than the color of their pixels. With an image there is no connection to database information and little opportunity to select except by color.
Drawings also have the advantage that the specific coordinates that define the objects within the drawing also define precise spatial relationships between those objects. The drawing provides a rich set of implied data by virtue of arrangement of the objects it contains. One can use drawings to compute relationships such as how much of a particular object is contained within a different object, or to find the longest line or the largest area.

Images have no such rich spatial relationships because they have no objects, only pixels. There are no objects in the image so there is no way to say where one object ends and the next begins. With images, where an object begins or ends or whether it exists at all is a matter of opinion, not geometry.

Some enthusiasts of an exclusively raster approach to GIS may complain that there are methods for assigning database information to regions of pixels and to “classify” or otherwise assign object characteristics to regions of pixels. However, what is really going on in such cases is the creation of a set of meta-information that is really a type of vector drawing. It is more efficient to simply use real drawings, perhaps in combination with images.

Restricted User Lifestyle

When using images to represent vector data better represented as drawings one often ends up with file sizes that are larger by a factor of twenty or more than the equivalent vector data set. Manipulating such large amounts of data takes profoundly more computer resources than is required for the vector drawing equivalent. The result from a user interface perspective is that operations with large images will be so slow that interactive work will be difficult.

When operations run many times slower the effect is a reduction in the quality of life of a user. A fast, instantaneously responsive user interface is a joy to use. It enhances the mental engagement of users with their work. A slow, tedious interface that requires pauses of many seconds between all operations causes unhappiness and stress. Using images inappropriately as replacements for vector drawings is a pathway to unnecessary stress.

Financial effects for using images are a real effect as well. When every layer in a map requires over one hundred megabytes the machine required for operation will be considerably more expensive that that required when every layer is a mere five megabytes in size. Because the number of pixels to be processed in an image goes up by the square of any increase in linear dimension, the processor speed required increases much more rapidly than the apparent increase in size of an image. Images that appear slightly larger could require twice the processor speed to maintain the same level of system responsiveness.

Therefore, the costs of running large images go up faster than the size of the images that can be reasonably used at various machine price points. Large images also require large amounts of RAM and larger hard disks for storage. Finally, projects involving large images are more difficult to transmit over Internet or private wide area networks for collaborative work than projects based on equivalent drawings.

Advice to the User

- Avoid using images to replace vector drawings. Instead, make a special effort to acquire the necessary vector drawings and invest time into formatting those drawings.
- If no drawing exists and only an image is available to represent a vector drawing (such as a scanned image of a paper map), invest the resources required for creating a drawing from the image. Use Manifold's tracing tools or hire a digitization contractor to create a drawing version.
- Sometimes, of course, it makes sense to bow to expediency and simply use a fast machine and a scanned image of a paper map.
- Use images for photographic data.
- Use images for data sets that represent continuously varying data such as terrain elevations, temperatures or other intrinsically “analog” data.
- Use images in combination with drawing layers to enhance presentations through artistic effects.
GIS and Networking

"A little learning is a dang'rous thing." - Alexander Pope

Few modern phenomena have taken hold as rapidly as the recent fashion for networking technologists to make money by taking advantage of the greed and stupidity of stock market investors. There’s no better way to start a stock market craze than by leveraging an exotic new technology or business method that the average investor does not understand. Add some pseudo-scientific gloss and you can take them to the cleaners every day. Even after a dot-com bust there are plenty of investors lined up to pursue the next big new thing.

The opening years of the new Millennium are an especially fine time to fleece investors with new Internet schemes or network-related glitz. At the time of this writing much of the world is riding a wave of immense prosperity compared to previous decades. Even with stock market declines, lots of people still have lots of money to invest. At the same time, math and science education in the US and many developed countries is at an all-time low. Never before in history have so many poorly-educated people had so much money they are willing to hand over to confidence men who can dazzle them with big words and mighty promises.

"GIS over Internet" is the GIS industry’s own contribution to fleecing the ignorant. By this phrase we don’t mean publication of images but rather the idea that GIS in local machines will be replaced by GIS done mainly on applications servers working with dumb, local clients.

As an Internet company that sells Internet Map Server software we would be the last to suggest that Internet is not in fact a revolutionary new way of communications. To compare Internet to the invention of movable type and its popularization by Gutenberg may actually be an understatement. Internet and the technologies it spawns will in our view result in a greater transformation of human society than the appearance of fast and easy printing technology.

However, just as the simple act of printing does not guarantee infinite wealth, just so simply using Internet does not guarantee sustainable wealth. To continue to make money in the long run one must use Internet sensibly. So as not to accidentally invest in really dumb ideas that are being promoted to take advantage of the Internet craze we have to understand some of the technology involved. Investing based on technical reality will help us keep our eyes open during market run-ups drive by speculative idiocy and will also serve us well in avoiding losses when investments based on fantasy collapse. Even if investing in stocks is not the game, understanding the fundamental conceptual errors behind GIS over Internet schemes will help organizations avoid the expensive mistake of investing in such schemes for their own operations.

Processor Speed and Internet Speed

Local area networks have continued to increase in speed to keep pace with higher speed local disk accesses. Small businesses and homes have shifted to hundred-megabit speeds and are beginning the move to gigabit networks while large businesses have already shifted to gigabit networks. People are using the speed of these local networks to make it much easier to reach out and get data regardless of where it may be stored. Modern local networks are therefore great at creating a transparent group computing experience when it comes to disk accesses.

However, disk accesses are only part of the picture of what makes for a modern computing experience. As fast as modern disks are, they are a thousand times slower than the fast parts of the computer. Hard disks typically work a few thousand times slower than dynamic RAM. RAM in turn works many times slower than the processor driving the system. Comparing the speed with which a processor talks to local RAM and local video memory to the speed with which a hard disk operates is literally like the speed difference between a fast bullet and a slow human walk. See the Using RAM and other Machine Resources topic for what this means to an application user.

This speed difference is an important factor because the human perception of computer response (whether we judge an application to be fast and responsive or slow and unusable) is largely driven by what happens at processor, RAM and video subsystem speeds. The practical limit on how cool or intelligent or responsive a modern user interface may be is largely determined by the speed of the high speed parts of the computer. This is something every 14 year old knows who has stepped up from playing a game on a slow video card on a slow processor to rocketing along with a fast processor and a big-time graphics engine with lots of megas of video RAM.

The speed of the hard disk or network has zero influence on the quality of the immediate user experience, because both are far too slow to participate in the user experience even in the slow case.

This speed differential calls up another factor that many GIS over Internet and Network PC investors fail to understand: As slow as hard disks and local networks may be compared to the bandwidth between processors and local RAM, Internet is many, many times slower. Consider that all the exciting talk in recent years about "broadband" Internet connections boils down to pathetically slow speeds, on the order of a megabit per second or so, a thousand times slower than a fast local network and usually millions of times slower than local system internal function.
If the difference between processor - RAM speed and hard disk speed is more than the difference between a speeding bullet and a human walk, then the difference between hard disk speed and Internet speed is literally like the difference between a human walk and the slowest crawl of a snail. Even a very fast connection to Internet is literally a thousand times slower than a local hard disk, and it is approximately a million times slower than local processor - RAM accesses.

Forgetting this key technical difference leads to business mistakes that are as dumb in their own way as the decision of the Tennessee state legislature one year to vote to make "Pi" a round 3.00... it just doesn't work. The plain facts of the matter are that Internet speeds are a million times slower than speeds achieved between a processor and its local memory. More importantly, although the speed at which processors and local memory communicate are getting faster every year Internet speeds are growing in speed at a much slower rate of improvement. This means that the arguments presented in this essay become stronger every year, not weaker. Quite soon, as processor - RAM speeds continue to rapidly increase while Internet speeds hardly increase at all, the difference between "in the box" speed and Internet speed will be like the difference between a fast bullet and a fast-growing plant.

**The Uses of Speed**

The main reason one needs speed is to support a high quality, modern user interface. A fast, elegant user interface tosses billions of bytes back and forth between processor and RAM to make the user experience smart and easy. Manifold System, for example, runs thousands of functions as a mouse drifts across a map. Every one of those functions depends on visual positioning and other factors to make the user interface more intelligent. Because human time is much more expensive than processor cycles it makes sense to throw processor cycles by the billions at even small tasks just to save a little bit of time for humans. The computer should have to work very hard so humans need not work so hard or study as much.

Even the fastest Internet connection is thousands of times too slow to support such sophisticated user interfaces. Remember that a processor - RAM connection is like a bullet to a walk when compared to a hard disk, and the hard disk is like a walk to a slow snail compared to Internet. Folks who make the technical mistake of thinking that Internet can support the same user interfaces as a processor - RAM connection are making as dumb a suggestion as it would be to suggest that a snail could play on a World Cup soccer team. Actually, it's worse than that. They are suggesting a snail can keep pace with a fast rifle bullet.

This is the main reason that GIS over Internet cannot handle the modern interfaces expected of modern applications. Internet is simply too slow. This is also the reason people do not do Adobe PhotoShop or other graphics editing across Internet, nor do they do even low-bandwidth tasks like word processing over Internet. Internet is just too slow. This is something everyone knows who has any actual experience of "Internet applications" such as web-hosted email. Such applications feature frightfully slow and stupid user interfaces that are hampered by the very slow speed of Internet. [They are also hampered by the "tragedy of the commons" effect whereby Internet connectivity is always automatically overloaded, but that's a different essay.]

GIS across Internet proponents often respond to this point by making a really stupid comment. They point out that Internet speeds are increasing every day. That's dumb because the comparison is not between Internet speeds of today and the speeds that Internet might achieve tomorrow. The comparison is between Internet speeds on any given day and the speeds achieved between processors and RAM "within the box" on that same day. Internet is getting faster, but processors and "in the box" speeds are getting faster still. The comparison is not to a fixed target, it is to a moving target driven by relentless speed increases in the link between processors, RAM and video memory.

Sure, modern DSL or cable modern Internet connections are fast enough to support user interfaces that are better than those on time-shared, Teletype printers or plain vanilla ASCII terminals as were common in the early 80's. So what? People are no longer satisfied with such interfaces. The requirement is not to grow Internet speed so that one day it will equal the obsolete user interfaces of the past. The requirement is to equal the elite user interfaces of modern times. It is a race in which Internet speeds are falling farther behind.

This is the key technical disconnect that wishful thinking and glib marketing often hide from the unwary. As technologists, we fully expect Internet and Java applets and such to get a hundred times faster in the next five years. Big deal. That's still a million times slower than the bandwidth achievable today by using local processors and local memory, and the Internet speeds of five years from now will still be thousands of times too slow to do a really first rate user interface by today's standards, let alone by tomorrow's standards. If one expects the standard for "power" user interfaces to improve in the future, then future Internet speeds will be even less suited to serve the user interface standards of tomorrow.

One main reason that Internet speeds are not increasing as fast as processor and memory speeds are increasing is that the speed of processors and RAM is driven mostly by local advances in silicon lithography and fabrication that are unconstrained by large scale infrastructure. Any improvement in any silicon fab quite rapidly circles the
The Network PC is simply the multi-user idea of a central processor and dumb terminals brought back from the
broader audience if the individual vellum sheets were razored out of the book, mounted in a pretty mount and sold
could be sold for a few thousand dollars as a whole book could be sold for tens of thousands of dollars to a much
completed data set. About 30 years ago rare book dealers discovered that a hand-written book on vellum that
The money factor in GIS over Internet has to do with the magic of selling the same thing piecemeal instead of as
the UNIX dream of a universal, quasi-dumb X terminal attached to a server into a modern
determinants of all technology: politics and money.

A final restriction on the speed of Internet for interactive computing processes is the speed of light. Already,
computers are so fast that speed-of-light issues are beginning to arise even over the short distances within a
computer. The physical distances between a client and a distant Internet server impose a crushing limitation on
speed as a result of speed of light travel time between the two, over distances that are millions of times farther
than intrachip distances. Although this may seem to be science fiction to the technically illiterate, something that
might be erased with a suitably glib disclaimer in marketing documents, the speed of light limitation is a genuine
factor in high technology that cannot be wished away.

In all fairness, Internet is fine for “batch” operations that are not interactive. It's also fine for presentations and
light-duty user interfaces. However, the issue is not the complexity of “batch” spatial operations that can just as
easily be done on a server as on a local workstation. The issue is the quality of a sophisticated, interactive user
interface, which is far more bandwidth intensive. One can easily write a fearsomely complex query in a few text
lines of spatial SQL. The point of modern GIS is avoiding the use of dumb text interfaces for such things
whenever possible and instead substituting a visual, seamless, point-and-click approach. Again, the point is to
use infinite machine cycles to save us humans from having to do drudge work.

We should also note that giving up one's GIS solution to an off-site server is a sucker trap that defies human
nature. It is simply asking too much of human nature to believe that any server operator will not over-sell and
under-power the server. As anyone who has ever used Internet knows, they don't call it the “World Wide Wait” for
nothing. In modern times a multi-gigahertz processor is so cheap that one now buys such supercomputer-class
machines for one's children to use on schoolwork. Who would want to timeshare any machine when we can have
our own personal supercomputer for lightning response whenever we want it? The buzzword for this in
organizations is "scalability" - if each new user brings a supercomputer class machine to the party, we can keep
adding users as long as we want without performance problems.

We think Internet is great for selling product, for delivering data sets, for synchronizing work groups, for publishing
summaries of work done and delivering updates and all sorts of work that does not require an intensive,
interactive user interface. Products like Manifold's Internet Map Server capabilities are great for such things.
However, if one wants a smooth, intelligent, sophisticated, fast, and assisted user experience, it's clear that
Internet-based applications will lag far behind modern technology applied "in the box."

Willing Slaves

So, why does one hear so much about GIS over Internet? We think it boils down to those two eternal
determinants of all technology: politics and money.

The politics are partly about Bill-envy and a desire to outflank Microsoft. The ill fated push into Network PCs
(billions of dollars down the drain on a really dumb idea) by an alliance of Microsoft competitors was motivated
mostly by a desire to wedge a crowbar between Microsoft and users. The idea of a Network PC is that all
intelligence and power should reside in a central server, which serves web pages to low-power machines that do
nothing but operate network clients.

The Network PC is simply the multi-user idea of a central processor and dumb terminals brought back from the
dead. It is recasting the UNIX dream of a universal, quasi-dumb X terminal attached to a server into a modern
lexicon of "Network PC" and "Application Server." The product-marketing basis for pushing Network PCs was
that it is easier to pry users away from Microsoft if the only application that needs to be ported is a browser. The
Network PC failed, of course, because neither PCs nor their users are stupid. The benefits of becoming a willing
slave to a central organization are far outweighed by the benefits of distributed, independent use of one's own
intelligent machines.

Another set of politics pushing for "Internet applications" revolves around big IT organizations discovering a fine
new tool to centralize everything once more. It may or may not be convenient to have someone else do system
administration but it is seriously convenient for organizational empire building when all computing activity is
centralized within the organization that runs the servers.

The money factor in GIS over Internet has to do with the magic of selling the same thing piecemeal instead of as
a complete data set. About 30 years ago rare book dealers discovered that a hand-written book on vellum that
could be sold for a few thousand dollars as a whole book could be sold for tens of thousands of dollars to a much
broader audience if the individual vellum sheets were razored out of the book, mounted in a pretty mount and sold
off one by one to collectors. Within a few years, an entire generation of manuscript books disappeared onto the walls of middle-class collectors as framed, single page ornaments.

Serving single images of maps over the web earns more money for database owners (either in a pay per view or as a lure for advertising) than selling the maps as complete digital databases. It's also a great way for the owners of digital map databases to retain ownership of the real GIS content. For public agencies who have come to enjoy selling public data for high prices it's a great way of being able to say they are meeting their mission of making public data available while in fact denying the public access to the real data. This allows the agency to charge high prices for data on CDs. It also allows bureaucratic expansion of programs and personnel needed to "develop" web pages instead of the relatively simple task of publishing data sets.

Another important factor in the money side of the equation is that there's a lot of financial pressure on traditional GIS companies to transform themselves into something other than a "old economy" software vendor. It can't be easy for someone who has spent decades building a GIS company to see a group of twenty-something web entrepreneurs achieve a valuation of a billion plus dollars in less than a year, merely because they thought up a better Ponzi scheme involving a dot com, or an LBS play or wireless play or whatever. Even with stock market declines, companies that can put a network spin onto their business are valued more in today's stock market than are ordinary software companies. Selling oneself as a "Maps over Internet" player is a great way to increase valuation.

Selling high and mighty web service ideas to technically illiterate investors is also easier work than competing with aggressive fanatics in software markets. If you were running a traditional GIS company, what would you prefer: fleecing Wall Street with web / wireless talk or risking financial ruin by getting into a price war with the likes of manifold.net? No wonder some GIS companies have promoted "GIS over Internet" like their lives depended on it.

We would like to point out that some institutional users with the best of intentions trick themselves into thinking GIS over Internet is a cost effective idea based on the notion that a browser costs nothing while a real GIS package can cost a lot. If the cost comparison is against some ancient ESRI software item that costs thousands of dollars a seat we can understand how such a cost comparison might be persuasive. However, if the cost comparison is against something like Manifold, which is inexpensive to begin with and heavily discounted in volume, then the idea of constructing an expensive web-interfaced GIS is a false economy compared to deploying Manifold on client desktops.

The web-based GIS will have a poorer interface than Manifold, so the human cost of actual use will be higher (immediately eliminating any savings of using free browsers compared to Manifold license fees). A more directly visible cost will be the cost of developing, deploying and maintaining a semi-custom web-based GIS system. This cost will greatly exceed the cost of Manifold licenses. Worse still, the Manifold licenses are a one-time cost while the maintenance and continued development (after all, we do want to keep up with progress in software) of the web-based GIS will be a massive recurring cost in every annual budget.

The Manifold Way

At Manifold we believe that a cool user interface written by experts that takes maximum advantage of "in the box" power will always far outperform a GIS over Internet solution written by equally smart experts. For serious GIS work the best user interfaces and the fastest, largest and most sophisticated spatial work will happen within your local workstation.

Web interfaces are fine for casual use to serve up "pay per views" and other visual summaries of GIS work done in the box. Internet is fine for such things and is a good way to provide reports and pictures of one's work to a worldwide audience. It's also a great way to publish a project that allows simple user interfaces for browsing and elementary queries. That's why we have an Internet map server within Manifold: for such uses it's a great idea.

For real work with real data, even simple work with simple data, corporate users will always have the best experience using a GIS like Manifold locally even if the data is remotely archived. Architectures like Manifold System Enterprise Edition allow users to gain the archival and control benefits of centralized data warehousing while retaining the performance and local response benefits of truly distributed computing, where the application runs locally "in the box."

It is also important that GIS consumers use their experience to argue against schemes by public agencies that bottle up public GIS data behind a "webstacle" that merely serves images. Don't stand by while someone says spoon-feeding a few images is adequate public access to public data. Point out that if the GIS data itself is not made available, giving a summary report in the form of a web-served, dead image is not an acceptable substitute.

There is no corporate IT argument for GIS over Internet that does not apply with equal force to other corporate asset bases and activities such as graphics arts, images, documents, spread sheets and other corporate data.
Whenever you encounter a “GIS over Internet” proponent, take a moment to ask them why GIS over Internet is such a good idea when PhotoShop over Internet or Microsoft Word over Internet or Excel over Internet is such a lousy idea.

Above all, remember the primary issue is not whether GIS over Internet is a good or bad thing. The key issue is whether it is worse or better than expertly implemented alternatives. It is also important to think clearly and not be fooled by whatever is the latest innovation in fleecing investors. See, for example, the What about Ajax? topic.

What about Ajax?
Using RAM and other Machine Resources
What about Ajax?

Some readers may come away from the previous GIS and Networking essay thinking that it no longer applies now that Ajax is in the world. That reveals a deep misunderstanding both of the previous essay as well as of Ajax, hence this essay to clear the air.

The short form of this topic would simply state that we are happy the web community agrees with the conclusions of the previous GIS and Networking essay and by embracing Ajax has finally and so whole-heartedly adopted the recommendations that essay first set forth several years ago.

But that would be no fun, as some Ajax advocates seeking the end of local applications do not really know what "Ajax" is and thus think it opposes or is an alternative to the notions in the previous essay. Their minds are often so confused by the acronym they don't realize they are in violent agreement with developers of local applications such as manifold.net. Precisely because manifold.net is indeed supportive of the real idea behind Ajax we would like to make it clear at the outset of this essay that the Ajax idea is our mantra, an idea we have put into action for many years.

Hotheads who don't bother reading the previous essay, this essay or who misunderstand their contents should therefore refrain from sending pointless flames to manifold.net accusing the company of not supporting such a wonderful, politically correct thing as Ajax. Such hotheads should avoid spontaneously combusting over matters that are not in dispute.

As a corollary, it seems that people's misunderstanding of this essay as well as their willingness to lose money in web application schemes using deceptive sound bites about Ajax is directly proportional to their failure to grasp the technical concepts set forth in the GIS and Networking essay. Therefore, that topic should be read first as it is the foundation for this essay about Ajax.

What about Ajax?

One hallmark of web-based applications promoters is their never ending ability to come up with new acronyms to confuse weak minded investors. "Ajax" is the latest acronym to enter the fray, and serves mainly to prevent imbeciles from noticing that a company has abandoned the idea of web-based applications (because they are too slow and barren) and has instead decided to get into the business of providing software that runs locally (because it is fast and rich). Like all such good deceptions, the acronym is wrapped within a cover story that evades precise definition and employs politically correct words that rubes can use to impress their friends without knowing quite what they mean.

(We assume the reader has read the previous essay and therefore knows with technical precision exactly why web applications run too slow and are barren in comparison to local applications that run fast and are rich.)

Ajax stands for "Asynchronous JavaScript and XML," referring to the putative theory of the acronym. The story begins by noting that on the one hand, people don't like long pauses in web applications while big images required for GUI maintenance or other information transfers occur, and on the other hand people are not usually continuously active when working with a web application. For example, someone might request a page of text from a web site and then spend time reading it and so not really be commanding the application to do anything while he or she is passively reading.

The Ajax story tells investors that the way web developers will get around the seemingly insurmountable technical problems listed in the GIS and Networking essay is to take advantage of the "dead times" when people aren't actively working. The idea is that the time-consuming action that makes web applications so lethally slow can be accomplished during the dead time when people aren't actively working, and so the user won't notice the application is lethally slow. This, of course, is a fairy tale. But like all good fairy tales it leverages some kernels of enduring truth.

The key fallacy is failing to realize that significant interactive applications such as PhotoShop don't have enough dead time to make up for the relative disadvantage of web applications compared to local applications, so just saying that we will toss images in advance of need doesn't quite do the trick. Ajax proponents concede that point, and therefore take their story further into territory that is not at all a fairy tale. The heart of the matter with Ajax is very true and something that Manifold very much puts into practice.

The Ajax story continues to say that the way to get around web limitations for web applications is to download the application into the local computer, where it can execute with the blazing speed and rich capabilities made possible through the use of distributed processing, local processor-to-RAM bandwidth and so on. You won't usually see it described that way, because Ajax partisans don't like to acknowledge the concepts set forth in the GIS and Networking essay as their reason for being. Instead, they say things such as "JavaScript running locally can be updated from time to time to avoid loading the network." But what they are talking about is not attempting
to run an application through the web at all but instead downloading it into the computer where it can run as a local application. The essence of Ajax is that local applications are better than web applications when rich applications are required.

The matter cannot be stated that clearly by web-centric companies because if it were, the web company promoting Ajax would see a decline in stock price as trend-conscious investors realized that the company was abandoning its essence as a web company and surrendering to Microsoft. No web company worth its inflated stock price will openly admit that Microsoft was right all along and that rich applications for the most part should indeed be run locally. So a convenient acronym is pressed into service that technically illiterate investors won't understand means "I'm doing the opposite of what I say." Using misleading acronyms is a time-honored way for Silicon Valley insiders and Wall Street professionals to fleece both the credulous masses as well as lethargic institutional investors.

The third part of the Ajax story line is the use of XML as the communications method between the local application and information tossed to it by some central web host. This and the explicit citation of JavaScript is nothing more than pandering to the insularity and stupidity of anti-Microsoft malcontents (there's one in every crowd) who would like to see the idea of democratic, distributed applications under every person's own control replaced by a centralized web application controlled by an elite web bureaucracy. Such people hate Microsoft so much they are willing to do whatever stupid thing comes along that promises to lever power away from Microsoft and from the desktop applications that Microsoft utterly dominates. Such self-destructive behavior, of course, assures that anti-Microsoft malcontents remain a tiny minority, a fringe element hovering around 5% or 6% of the worldwide base of computer users.

This fringe element does enjoy visibility despite their small numbers because for competitive reasons they are aided and abetted by companies who compete with Microsoft, such as SUN, who are forever hopefully coming up with new tricks and baubles, like Java, that don't really change anything but which they hope will provide a rallying cry for their partisans and a distraction for Microsoft. A deceptive way of presenting Ajax is one such trick.

Real men, of course, compete on the merits and don't resort to evanescent tricks. As Tacitus says, they "fight sword in hand, taking their wounds in front." In computer terms that means not saying you are doing a web application when you are really delivering a local application, and it means doing a better job in local applications, which continue to be the decisive battlefield, than your competition. That takes real effort and if you lose that contest no amount of smoke and mirrors will prevent an ultimate decline in market share.

For example, the result of the fundamental combat between SUN and Microsoft in the main contest over local applications is that SUN took their operating system and their applications ecosystem in hand against Microsoft's operating system and applications ecosystem and SUN decisively lost. SUN overwhelmingly lost despite enjoying a starting position much more powerful than Microsoft's when combat was first joined. Almost everything which followed that decisive loss is just a sideshow, as continues to be demonstrated by the plummeting fortunes of SUN.

As a side note, it is interesting that for all of its flaws Apple stands alone as one of the few system alternatives to Wintel, partially because Apple has continued to manfully compete with Microsoft through head-on competition over the merits of desktop applications, sword in hand wielding an applications suite of exquisite elegance and style.

To return to Ajax and the choice of language and communications protocol embedded in the acronym, experienced computer science professionals know that the choice of a particular language or a communications protocol is irrelevant except to the degree that it affects measurable parameters such as performance. If anything, citing a particular language or protocol reveals an amateur fascination for transient trivialities over paradigm-shifting substance.

On the trivialities front, an interpreted language such as JavaScript is a strikingly poor choice for efficient code exchange and an appallingly bloated format such as XML may be the worst choice for a machine-to-machine communications format imaginable, second perhaps only to Braille, in terms of raw efficiency. There's no point in bloating up a communications medium to make it "human readable" when it will be used only for one application to exchange data with another application.

But then Ajax as it is misrepresented is not really about computer science, it is about politics and fleecing investors, and so one must use technologies that serve those purposes rather than efficiency. JavaScript and XML are perfect for that purpose as they deliver a guaranteed anti-Microsoft pedigree and by their very sound convey the required attitude of disdain for desktop applications.

Since few people in web applications really know what Ajax means and since many people saying they use Ajax really mean only that their web application is written in JavaScript and uses XML in some moronic way, let's take a look at a true Ajax application, Google Earth, to see how the Ajax thing is done by bona fide experts.
Google Earth is the newly famous “web application” that allows people to fly about visual representations of the Earth with amazing speed. The application allows people to move from place to place, using a highly appealing GUI that seems to let users zoom from one region to another as if they were flying in from space to see details of a particular place. Google Earth’s claim to fame among investors and web application proponents rests upon the belief that the technical genius of Google, using Ajax, has made it possible for a web application to be as fast as a local application. That would be an amazing story if it were true.

The truth, of course, is that Google Earth is fast not because it is a web application but rather because it is a local application, an enormously large one, that is downloaded into the user's computer when the user signs up for Google Earth. Thereafter, the application is updated from time to time just as any local application might be through updates or service packs. Most functions of Google Earth are executed locally “within the box” for the reasons discussed in the GIS and Networking essay.

It’s true that Google Earth expertly employs the Ajax GUI shell game of moving imagery into position while the user's eye is occupied doing something else so that the user does not notice the lag. Just as a seasoned magician distracts the audience's eye with one move while covertly building an illusion with an unnoticed hand, such shell games are a part of every expert programmer's repertoire of GUI techniques. This is one of the key ideas of Ajax, but when people describe it as something new one wonders just how negligent their educations must have been for them not to know this sort of thing has been a routine part of programming for many decades. Even so, it has rarely been done as deftly as by Google Earth.

In Google's case, that is why when a user wants to jump from viewing one particular region to another Google Earth insists on zooming out from that region to a viewpoint in space and then zooms back down from space to the new region. The time spent zooming out to space and then back down to the new region keeps the user occupied with a pleasant joyride into space while Google Earth begins downloading part of the new, detailed image that is required. On our way out to space and back we don’t notice how much time has elapsed.

When the user zooms back to Earth the more detailed image already has some central tiles streamed into the application, and while the user's eye is drawn to the center more peripheral tiles and more details of the image can be streamed in, hopefully with less notice of a time lag than if the entire image were brought in at once. All this works very well and is impressive, a truly masterful GUI that combines the psychology of user perception with the power of local applications and the utility of fetching small data from the web.

But the key notion is that Google Earth is indeed a local application of the sort that Microsoft has built for years. The speed and power of Google Earth arise mainly from the idea of distributing applications away from centralized, time-shared servers into local desktop machines. It is, of course, a local application that is downloaded via the web, but that's something local applications have done for many years, a valid use of the web as a distribution medium. Likewise, it's true that the application fetches data via the web to display, but again, that has been done for many years by local applications. As we’ve argued in the GIS and Networking essay the web is a fine medium for distributing applications or for delivery of relatively low-bandwidth information.

The core idea remains that Google Earth, like all functioning “Ajax” applications, is really a local application running on the local machine, not a web application running on a central server. Running rich applications locally is the core idea in the GIS and Networking essay and is the core idea behind the personal computer revolution that killed off centralized, time-shared minicomputers. It is still the core idea that keeps companies like Adobe and Microsoft and AutoCAD thriving. And now it is Google's turn to discover that rich applications can be done faster and better by harnessing through local applications the distributed power of billions of desktop processors. The question is how can Google leverage that discovery to compete with Microsoft without investors realizing that Google now agrees with Microsoft on the power of local applications.

The business and financial problem for Google is that the company has tied its financial worth to its identity as a web-based, modern replacement for the local-based, stodgy ideas of ordinary, local software vendors like Microsoft. Google cannot openly admit that the web doesn’t work for rich applications and that to deliver such rich applications it must get into the business of creating and providing local applications just like Microsoft. If it became evident that for growth into rich applications Google must, in effect, abandon the idea of time-shared sales of applications running on its own servers then perhaps even the most credulous Wall Street analyst might have to consider the complexities of competition with Microsoft in the local applications market, a fierce arena where one's talents with the sword must be sharp indeed.

The bottom line for the three-way Ajax story is that the only part of it that has distinctive meaning is the notion that web-based applications should be abandoned in favor of running local applications within the desktop machine if the objective is rich software. That's the entire point of the GIS and Networking essay and we are glad to see that Ajax partisans have taken the time to read that essay and to adopt its conclusions. But we are dismayed to see the conclusions of that essay used dishonestly in an attempt to fool investors, as the Ajax story is normally employed.
Some readers may object to our characterization of Java and XML as a sideshow or as "baubles" used to distract the natives with glittering trinkets. Such readers might fairly note that Java has evolved into a multi-billion dollar industry. That avoids the main point, as markets for languages can arise and thrive independently of the strategic consequences of using those languages to achieve dominance in operating systems and applications. Fighting and winning over applications depends upon what is done with the languages used and not upon the choice of programming language. Choosing a particular language no more guarantees success in applications than GM's choice of English units or Metric units for bolt sizes guarantees it success against the formidable quality and functionality of cars produced by Toyota.

We trust the discerning reader understands we do not in any way suggest that Ajax as a concept is a bad thing. On the contrary, except for the mindless embedment of JavaScript and XML, the whole idea behind Ajax is that the GIS and Networking essay is right and that rich applications should be run locally. Quibbling over minor details such as how the application is delivered or whether or not it fetches data from time to time from remote sources is missing the forest for the trees. If you support Ajax, whether you realize it or not you support the core conclusion of the GIS and Networking essay, that rich applications demand the distributed processing and rich bandwidth of local execution.

Likewise, we don't mean to criticize Google Earth in any way. "Earth" is a virtuoso application, an absolutely masterful implementation that any computer science professional will enjoy and cite as a distinctive accomplishment. But it is masterful precisely because it is a local application and for its core functioning abandons the idea of executing all that elegant code on some centralized server farm instead of within the user's local machine.

The dissection of Google Earth in this essay serves mainly to illuminate the difficult business task now facing Google as it expands into real competition with Microsoft, to balance the technical imperatives of casting more function into local applications with the business imperatives of not becoming seen as a local applications company by Wall Street. That is not an easy task even for business leaders with the proven skill of Google's management.

But while Google and Microsoft battle it out in the big leagues, users considering how and when to apply applications should not allow themselves to be fooled by misleading use of acronyms, like Ajax, into thinking that a local application is a web application or that web applications can magically avoid the issues set forth in the GIS and Networking topic.

The wise developer and investor will also not allow themselves to be led astray into wasting resources on activities that do not deal with the fundamental challenge, to deliver a high performance experience on the local desktop that cannot be outmatched by any competitor who knows better how to wield the power of distributed, local computing. Whether you call such efforts to harness local computing "Ajax" or whether you call it business as usual in the competitive world of Wintel applications, the task still remains to master all aspects of high performance local computing.

And for our users, when they are asked their opinion of Ajax we hope this essay will encourage the immediate response, "Yes, I think Ajax is great and that's why I use Manifold!"

GIS and Networking
Using RAM and other Machine Resources
Using RAM and other Machine Resources

Before reading this essay, please read the Performance Tips topic if you have not already done so.

Manifold System was designed for the modern era of desktop machines. How is the modern era different from ancient days?

- Random Access Memory (RAM) is cheap.
- Disk storage is free.
- Processors are cheap.
- Graphics is both fast and cheap.
- Local networks are fast.
- Humans are very, very expensive.

Machine Architecture

Let's take a moment for a quick refresher on key factors in machine performance. The fastest thing in your computer is the processor. Modern processors will run at well over a gigahertz in speed with certain internal parts of the processor running several times faster. Modern processors are so fast that they end up spending much of their time waiting for the slower parts of the computer system to catch up.

The second fastest thing is RAM, which usually operates at a third to a fourth of the speed of the key parts of the processor. The third fastest thing is the video subsystem, which usually consists of dedicated video RAM, a graphics processor and video circuitry that can read/display from video RAM at the same time that the graphics processor or main system processor can work with the video RAM. It is often said that the human retina is brain tissue that has been extended out into the eyeballs for the purpose of acquiring visual info. In a manner of speaking the RAM in video subsystems is like that in reverse: it is part of the processor - RAM ensemble that has been extruded out into a display subsystem for the purpose of projecting visual info.

A bottleneck in the high-speed part of your machine is the linkage between the processor and RAM. Processors are so much faster than ordinary RAM that it pays sometimes to install a bit of extra high speed RAM, a cache, so that for many memory interactions the processor need not be slowed by RAM. It also affects the speed and power of graphics cards that must exchange lots of data at high speed with the processor and system RAM.

[An aside: using graphics processors as massively parallel computing engines is an exception to the above simple case view. Such architectures are best understood as massively parallel supercomputers residing within the graphics card served by their own local RAM, which are connected to the "other" computer, that is, the CPU and its resources through a very fast parallel system bus connection. If you have one of those installed and can use it, the architecture of your computer is re-shuffled so that the fastest thing becomes the GPGPU and its very fast local RAM, assisted by a supporting cast of very fast CPU and its local RAM. The meaning of this essay still holds, because such ensembles are thousands or millions of times faster than anything else, in particular, faster than disks or local area networks.]

Compared to the three-way ensemble of processor, system RAM and graphics engine everything else in your computer system runs thousands of times slower. It’s quite literally the difference between a fast bullet and a slow walk. For example, the next fastest things in computer systems after processors and RAM are hard disk drives and the local network interface.

Hard disk drives and local networks are extremely slow compared to processors and RAM. A fast disk might have an average access time of a few milliseconds, which is over a thousand times slower than the microsecond access times typical of RAM. Although hard disks can transfer data faster once data is found they are nonetheless best understood as subsystems that are a thousand times slower than RAM.

Even hundred megabit or gigabit networks are also extremely slow compared to processors and RAM. At best, although the fastest purely local networks have the potential to go faster, even a good network interface will end up being about as fast as a local hard disk. This is one of the main uses of a fast network, to enable the dispersion of hard disk storage to different machines on a local network without any performance penalty attached to using a disk on a different machine. That this is accomplished is not a tribute to the speed of the network but rather an indication of how terribly slow hard disks are compared to the speed of processors and RAM.

An aside: Internet, by the way, is idiotically slow compared to even slow things like disks and networks. If the processor and RAM are like a fast bullet, and hard disks and local networks are like a slow walk by a human, then
even a fast Internet connection is like a snail. Suggesting that doing GIS over Internet is a better idea than doing GIS locally is like suggesting that snails are fast enough to outrun bullets.

For a software designer the main message of the above is that keeping the entire application in RAM so that it executes at processor and RAM speeds means we can make the application go a thousand times faster than if we have to use hard disk. That's a payoff too big to overlook in an era of cheap RAM.

For someone buying software and hardware it means the most important hardware investment is in the amount of RAM installed. Lots of RAM means that the processor will not be standing around waiting for the hard disk to provide paged data. More RAM is usually better than investing in a faster processor because without adequate RAM it doesn't matter if the processor is faster: both a fast and a slow processor will be spending most of their time waiting for slow fetches of paged memory from hard disk.

This effect, by the way, is one reason why Intel processors surged ahead of other processors for UNIX use in the late 1980's even though Intel 386 and 486 series processors were usually slower than the Motorola, SPARC or Alpha alternatives. The Intel processors could be purchased within PCs where RAM was much cheaper than RAM sold for use in the more expensive workstations that used the faster processors. PC clones loaded up with lots of inexpensive RAM were more effective UNIX platforms than fast workstations hobbled by small amounts of expensive RAM. The extra RAM made the PCs faster overall even though their processors were slower.

The same effect is repeating itself in the second decade of the new millennium, as yet another generation of computer users discovers that tossing lots of inexpensive RAM at a task in local processing makes life go really fast and pleasant. Once again, people are discovering through personal, bitter experience that if performance and a rich user experience are the goals, time-sharing over very slow networks is a terrible idea for anyone except the time-sharing salesman.

**Manifold Architecture**

The good news is that RAM is cheap. At the present writing, 12 GB of RAM (eight gigabytes) retails for under $200. At such low prices it is simply criminal not to have at least 4 GB of RAM. Manifold therefore expects that we will have lots of RAM in our machine. Occasionally, one reads criticism of Manifold that the system uses a lot of memory. If the memory is available, of course it does! It would be irresponsible not to do so. By using RAM whenever possible Manifold assures that it will run very fast. You must, of course, run 64-bit Windows to take advantage of lots of inexpensive memory. See the 32-bit and 64-bit Manifold Editions topic.

There is no point in slowing down the system so that it uses disk just in case the user has not invested in RAM. Such architectures penalize all users including those people smart enough to have spent a few pennies on RAM. To use this RAM, of course, it is important to have a modern Windows system such as Windows 7 x64 or Server 2008 x64 or XP x64 that does a good job of managing large amounts of system RAM. Investment in RAM and into modern Windows is very smart.

Manifold also expects we will have lots of hard disk space on our machine because disk space is now free. Perhaps it is not completely free but it is so close to being free that for all practical purposes it is free. For under $100 one can now purchase over a terabyte (one thousand gigabytes) of storage. At those prices inadequate disk space should no longer be a factor for most people.

In contrast to the low cost of RAM and the essentially free status of disk space the cost of educated humans has skyrocketed. Almost anything we can do from a hardware perspective is worth doing if it saves human time. This is one reason that Manifold now saves all components of a project within a single .map file. By keeping all data in a single file we eliminate any wasted time hunting about for different files that make up a project.

Finally, Manifold expects that one has a modern graphics card installed with serious hardware support for graphics, GPGPU capability and well-written graphics drivers. Very hot graphics cards with massive amounts of dedicated graphics memory are now commonplace and dirt-cheap. There is no reason to waste the time of a user with slow graphics when lightning-fast graphics is cheap. If we can utilize GPGPU computing (see the NVIDIA CUDA topic) it is crazy not to spend $100 or so for supercomputer performance in those functions.

**Good Business**

Manifold's business structure is designed to exploit the interplay of the above technical factors. The low price enables users to invest into modern Windows, lots of RAM, fast processors, fast graphics cards and large hard disks. These machine resources will serve you every day no matter what application you launch. Many users will already have modern machines in place and will need no investment at all.
The main difference between Manifold and other, non-GIS applications is that large GIS projects involving images will often be the very largest jobs in memory usage ever executed on a particular machine. GIS images, for example, can easily grow to tens of megabytes or even hundreds of megabytes. This is much, much larger than images typical of simple graphics arts work and a factor of ten or greater than even very large word processing documents. Adding RAM is therefore an expected step for serious GIS work involving large images.

Some readers are blessed with modern systems and will not have to worry about hardware resources. Others have to make do with less contemporary hardware. As time goes by and machines improve a 3 Gigahertz processor will be something so slow it is purchased only for children's machines. In that time a reference to a Core i7 will seem positively antique. However, there are many people in the world who will be using slower systems for years to come so we offer the following advice.

Some suggestions when assembling a new system:

- Just about any AMD or Intel dual core or quad core with 1 or 2 GB of RAM and Windows from XP to Windows 7 will be fine for working with small drawings in an ordinary vector GIS way. Databases and drawings are low-overhead items.
- When working with images, we suggest at least a quad core machine with 4 to 8 GB of RAM running Windows XP x64 or Windows 7 x64. This is excessive for small images but necessary for mid-sized images. In modern times, most people buying new machines will buy at least this much anyway. Images are computationally intensive.
- RAM has become ludicrously cheap. Many Intel Core i7 machines can host 12 GB of RAM. Buy lots and lots of RAM. It's dirt-cheap and it saves you time, which is very expensive.
- A fast graphics card must be installed when performing 3D rendering in terrain windows. NVIDIA-based cards currently selling for under $50 will provide smooth motion even with large terrains. We like cards using NVIDIA graphics processors and strongly suggest getting the hottest NVIDIA processor-based card you can afford. Using NVIDIA CUDA can be a huge performance advantage as well.

See also the advice in the Performance Tips topic.

As a reality check keep in mind that one can configure an incredibly hot machine and purchase Windows, Microsoft Office and Manifold System and still have thousands of dollars left over as compared to the cost of buying just the same GIS software capabilities from a legacy GIS vendor. On occasion, one encounters people who seem proud of having burned up many thousands of dollars per seat on legacy software that does less than Manifold. It is especially funny to realize that these are often the same people who complain about no longer having enough budget to afford modern machines, adequate RAM or even an upgrade to 64-bit Windows 7.

If people within your organization oppose increased Manifold procurement a good approach is a table in two columns that in one column lists the cost of legacy software required to approach Manifold's capabilities. In the other column one can present a list of all the wonderful modern hardware and software one can afford as a result of purchasing Manifold. The difference is real money that has a real impact on machine capability and organizational output.
Public Access to Public Data

manifold.net is committed to supporting public access to public data. We also support unrestricted use of cartography, which we see as a form of free speech. We believe in modern times that it is not possible for free people to freely participate in democracies unless they may also freely utilize digital maps.

This essay is not a rant against maps that are sold by commercial entities. People and companies should be able to create new maps with an expectation that they will be able to sell those maps for a profit. However, we think government maps and GIS data created by the government are a special case. If they are placed by law into the public domain they should be made available to the public.

Civic Life Depends upon Free Access and Usage

Many aspects of civic life are defined by geographic considerations or are profoundly influenced by the geographic context in which they occur. In modern times, the use of digital data by governments and societies has become so interwoven into politics and ordinary civic processes that the maps used to drive decisions and debates are digital ones. GIS software running on computers is required to view and to manipulate such digital maps. To an increasing degree, the image of the world that is used to govern its citizens is a purely digital representation.

If you are forced to use only paper maps, you are barred from seeing or working directly with the data sets that are often used to make decisions. Instead of being a participant in democratic decision-making, you become the recipient of decisions already reached. Note that the popularity of web-based "map servers" does not remedy this situation, since such web servers provide a picture of the map and not the actual map itself. With the actual GIS data one may be a participant; when provided with a report, one is merely a recipient.

If you are charged a fee for access to the maps upon which government decisions are based, you are being charged a poll tax on your right to participate as a citizen. Free maps are essential to the democratic process. This does not mean that all maps should be free of charge, but it does mean that the maps created and used by government should be free or nearly so.

A corollary is that government maps should not only be free of charge, they should be free of usage restrictions. If the government tells you what you can do with the map, it is the same as if they told you what you could say with your words. Perhaps there is no charge for speaking, but you may not speak freely. Free usage of maps extends to the right to freely reproduce them and otherwise to use them and to provide them to others as you see fit.

In the United States, GIS users have become accustomed to free access via Internet to a very wide range of maps. Manifold imports so many formats that one could spend a lifetime downloading and viewing maps and still not see all that are freely available. However, despite the immense richness of the US GIS data wonderland, it still lacks many key GIS data sets that are required for informed citizen democracy:

- It comes as a surprise to many technologically-literate people that even today, using the full resources of Internet, one cannot get a full set of digital maps of the world that are both usable by ordinary individuals and are free of usage restrictions. If NIMA’s VMAP1 were made fully-available, this major restriction would end.
- Until the publication of the first Free World Time Zones maps (by the Free World Maps Foundation), one could not even get free maps of time zones (!) for the United States and the world. There is still no official set of maps available to the public.
- Telephone Area Codes affect life and commerce and are a key aspect of telephone communications. They are heavily regulated by government and the subject of numerous laws and regulations, but one cannot get a map of telephone area codes that is both free of cost and free of usage restrictions.

In the United States there seem to be two contradictory trends in public access to public data. On the one hand, more public data than ever before is being published on the Internet for free download. On the other hand, many public agencies ignore laws guaranteeing public access to public data, or they are providing the data in a form that renders it unusable by the public. In general, there are good news trends and bad news trends. We believe GIS users have a civic duty to educate the public and their representatives in government to encourage the good news trends and to reverse the bad news trends.

Good News and Bad News

Recent trends provide good news and bad news for free people who wish to use modern maps:
Good News:

- Affordable GIS Hardware - Personal computers have become so powerful in recent years that anyone with an average PC can enjoy GIS capability with capacity and processor speed greater than the computers originally used to create most of the world's digital maps. As a practical matter, the cost of hardware is no longer a barrier for individuals in developed areas or for most organizations worldwide.
- Affordable GIS Software - Recent advances in GIS software, driven by the PC technology revolution, have made sophisticated GIS capability (like that in Manifold System) available at prices affordable by ordinary individuals.
- Expanding Public Domain data sets - Led by the United States, an increasing amount of government-originated data is emerging that by law is in the public domain and thus, in theory, is available for free usage.
- Internet as the Great Equalizer - Internet makes it possible for people around the world to cooperate as equals to promote public access to public data. The low cost of communications and data interchange over Internet makes it practical for maps to be created and exchanged using teams of people in different countries. Because it is technically difficult for governments to censor Internet interactions, even people in countries where free cartography is illegal can benefit from freedoms in other countries.

Bad News:

- State Cartographic Monopolies - Regrettably, the citizens of many so-called "free" societies must still purchase the landscape of their democratic discussions from a state-run monopoly and must utilize the maps so purchased only as allowed by the licenses granted by the state. Outside the United States, this is the rule, not the exception.
- Attacks on Cartographers - Repressive governments often restrict cartography by private citizens. Such restrictions are prompted not by an uneducated fear of cartography but by a calculating, politically informed awareness of the utility of cartography. Citizen use of electronic maps supports undesired activities such as self-assembly, free speech or economic competition with the government. Mercator himself was imprisoned after his travels for cartographic purposes triggered government suspicion. Some repressive regimes ban citizen cartography as a means of maintaining dictatorships. Other countries, including some so-called "free" Western democracies, make it illegal for private citizens to engage in cartography. The ban helps maintain the state-run cartographic monopoly.
- Repressive Influence on "Free" States - Some state cartographic monopolies have influenced agencies within free countries such as the United States in an attempt to prevent freely usable data from emerging that may threaten the state monopoly. In the US, for example, as of this writing the National Imagery and Mapping Agency (NIMA) has refused to release to the public many parts of "VMAP1", the public domain, non-classified, highly detailed world map it possesses, in part because of influences from state monopolies outside the US. The sharing of data between governments has now introduced the repressive policies of some state monopolies into formerly free areas. It also appears, in our opinion, to have become a handy excuse for rogue agencies to maintain an imperial disdain of statutory requirements to make public data available to the public.
- Denial of Public Access - Some agencies simply refuse to provide public access to data or restrict access to approved users. If it is truly public data, you have the right to access it. Some agencies will not release public data to ordinary individuals, researchers or others not meeting their criteria for an approved user, or they will attempt to place a restrictive license on data in the public domain. Some agencies will make chilling statements about the law that are flatly untrue. For example, the Census Bureau at one point published instructions for TIGER/Line recipients that told them TIGER/Line was a trademark of the Bureau and that any usage of TIGER/Line data must be accompanied with a notice to that effect. That's simply wrong, since one can use this public domain data set however one wishes without any need to publicize the Bureau's trademarks. In another case, the EPA used restrictive licensing to deny access for years to the general public to important public domain GIS data and code regarding chemical emergencies.
- Privatization by Public Agencies - Some agencies in the United States are privatizing public data and selling it back to the public as "products" using the lexicon and practices of private business. Although US law requires agencies to provide data for no more than the cost of copying and distribution, some agencies charge far more than allowed by law. The resources available to agencies are so great and the cost of utilizing the legal system in the US is so high that as a practical matter few people can afford to challenge even blatant violations of the law. Some agencies still charge thousands of dollars for data that costs tens of dollars to reproduce and distribute. In an even more disturbing trend, some agencies have registered trademarks on public domain data sets and have used their registration of the trademarks to attempt to prevent any "competition" from sources redistributing the public data for free.
- Privatization of Public Data by Private Firms - One increasingly hears of key public data sets becoming privatized through opaque dealings with private firms. For example, by law telecommunications and telephones policy such as tariffs are a matter of public record in the United States; however, it is not currently possible to discover a map as fundamental to telecommunications debate as is the map of telephone area codes. A private contractor currently holds this map as a privatized data set. If you do not have free and open access to such maps as a private citizen you will forever be kept at a disadvantage in public hearings on telecommunications policy. In another example, the Census Bureau once released a CD that stated a commercial GIS vendor's license (who was involved in the production)
controlled all data on the CD including the 1997 Statistical Abstract of the United States, an indisputably "public" data set. In 2001, the USGS effectively privatized the entire body of SDTS DEM files by delivering them in a de facto, exclusive deal to a small private company in Florida for distribution.

- Privatization through Private Influence on Federal Agencies - A subtle, but very real, means of privatization of public data occurs when market concentrations in GIS software causes governmental agencies to publish public data in proprietary, private formats that require the permission of private companies for people to fully use the data. For example, much Federal data is published in ESRI's undocumented .e00 format. Although firms like manifold.net can discover the contents of such formats, there are very few other firms who can do so. In addition, there is no guarantee of transparency of data as would exist if the data were provided in an openly published format such as ESRI's .shp format. Although agencies could publish the data in an openly published format such as ESRI's .shp format, they will nonetheless at times publish data only in .e00. At times it seems that some agencies have a promiscuous interest in releasing data only in deeply proprietary formats, such as ESRI "geodatabase" formats that not only are deeply proprietary but require the vendor's latest products so that even licensees of the vendor's earlier products cannot use such data. We feel this is a matter that education and awareness can help solve. However, it is a very important matter since to the degree any agency publishes data in a proprietary format it is not publishing data that is freely usable by the public.

- Illegal restrictions by indirect requirements of tools - Some agencies which are required by law to provide public data in open formats will nonetheless use proprietary formats where the only tools available enforce proprietary restrictions. For example, a common misconception is that .sid format is OK to use for public data because the makers of the format at Lizardtech (an appropriately reptilian name) provide a "free viewer" which can display the data and export it to open formats such as GeoTIFF. However, if you try to acquire and to use that "free viewer" you'll find that it is a licensed, proprietary tool which requires users to agree with Lizardtech's grossly objectionable legal positions as a legal requirement of using the tool. It is a bit like justifying illegal restrictions on your right to vote by saying that they are not a factor if you sign an agreement saying that you can vote, but only on the condition that you agree your voting rights can be taken away at will. Such restrictions may not be objectionable to some users, but they will be objectionable to competitors of the proprietary data format (for example, ECW or JPEG 2000, both available in open source code) which restricts the ability of a wider community to utilize that data for the convenience of end users.

- Privatization by Researchers - As open as scientists normally are, there are few communities as secretive as "Big Science" can be at times. Many images of our world are in the form of public domain maps and data created by NASA and other government Big Science initiatives; however, these can be surprisingly hard to get when researchers feel a need to "protect" data from access by an unknown public. Numerous scientists are very open about sharing data, so we certainly don't wish to suggest that science overall has become "closed". However, it is not fair to criticize government and private firms for privatization of public data without acknowledging that the scientific community has been remiss in this area as well. Researchers withhold public data from the public for a variety of good and bad reasons, but if the result is to deny public access to public data the result is bad for democracy.

- Privatization through "Webstacles" - A "webstacle" is the use of the Internet to avoid providing data to users. This is often the unintended result of good intentions, but at times webstacles are used to inappropriately privatize data. Here's how it works: an agency spends a few million dollars creating data. Rather than provide it for free download via FTP, they spend a few more million dollars creating a "map server" web site that spoon-feeds data to users in the form of dead images served over the web. The agency then says "we are fulfilling our duty of providing the data to the public through this web site." What's really going on is that the public cannot get free, public access to the data. The web server does not provide any data, only reports on the data in the form of images. If you don't like what the agency decided to show you in those images or if you wish to use the data in your own maps or analyses, tough luck. Further, webstacles traditionally only provide microscopic glimpses of the real data set. The agency has no risk that public users might ever actually get their hands on the entire data set. The result of the webstacle is that the data set remains inaccessible to the public. Map servers are a great idea if they are backed up with an FTP site or other means of making public data truly accessible to the public, but they cannot be considered a source for data if all they do is serve images.

We think on the balance it is possible to leverage the "good news" above to defeat the "bad news." When free citizens around the world join their GIS expertise via Internet, it only requires a single copy of a public domain dataset to emerge in order to defeat the "bad news" reported above. Likewise, it is possible to engage in cartography in those countries where cartography is still legal to defeat government restrictions on cartography in repressed societies.

What You Can Do

Here are specific actions you can take to promote public access to public data:

Appendices

4305
Learn about copyright laws and Federal and State laws providing public access to public data. If you know the law, you’ll know when someone is trying to restrict your rights under the law.

Learn about the GNU "Copyleft" license used to publish GNU and Linux and how it can be used to publish GIS data in a way that will prevent its subsequent privatization.

Learn how to use the FOIA and how to make and pursue FOIA requests for GIS data from Federal agencies.

Publish public domain maps and GIS data sets you obtain using the GNU license. Provide them to people who run servers allowing free download.

If you provide map images via Manifold’s web server capabilities, consider providing access to the underlying data via FTP as well. This is not always appropriate for commercial data, of course, but all public agencies providing public access to public data should attempt to do so.

Encourage authors of public domain cartographic data sets to publish data under the GNU license. Do not patronize vendors who attempt to privatize public data or who reprint public data at unreasonably high fees. Support commercial vendors who provide real value added or original data by purchasing their products.

When you encounter a federal or state web site that features webstacles instead of real data, contact the administrator of the site and ask them to include links to real data in downloadable form. Some agencies mean well: because their agency uses over-priced software they think that GIS costs many thousands of dollars per license so they put effort into providing images in the belief that the public cannot afford to work with the real data. Set them straight: tell them that Manifold makes it possible to work with the most sophisticated data to as great a degree of sophistication as one chooses at prices no higher than ordinary Microsoft Office applications. Tell them the more sophisticated the data is, the more important it is that users be able to work with it as real data.

File Freedom of Information Act requests with US governmental agencies (or the equivalent with State agencies) to obtain GIS data that is not provided to the public. If after asking politely for the real data behind a "webstacle" web site the agency will not give it to you, make an FOIA request for the data. Sooner or later the webmaster will realize that it is easier to provide a link on the site than to respond to a FOIA request. Very important: once you get data in response to a FOIA put that data into circulation so that other people can get it without repeating your FOIA request.

Educate federal, state, and local government worldwide on methods of publishing data to promote free map usage. This would include technical advice to avoid "privatization traps" such as publication in proprietary formats, as well as offers of free redistribution and access to Internet for organizations that do not have the technical resources or budget within their agencies to offer data that is being accumulated. Explain the difference between serving images and providing access to original data.

Complain to your Congressional representative and Senators about clearly illegal actions by federal agencies such as illegal FOIA responses and clearly illegal privatization of public data. Of course, unless you have given your Congressperson money in the form of political contributions you cannot expect any assistance but even in modern times there are surprisingly many Representatives and Senators who have directed their staffs to take an interest in legitimate complaints raised by "ordinary" people. Therefore, it is not totally an act of naivete to raise a complaint with one’s Congressperson. If your Congressperson ignores you (as they almost always do on matters that require any thought) and you are among the one tenth of one percent who can afford to use the US justice system, litigate the denial of your FOIA request.

If you choose to take legal action over illegal agency actions, such as illegal responses or denials to a FOIA request, seek out allies. Many legal firms will have a "pro bono" (for free) program of contributing legal work for public causes. Seek out organizational allies and other people who may be affected by the illegal action. For example, NIMA’s refusal to release the VMAP 1 coverages for Vietnam (clearly US origin data) is a slap in the face to the many US veterans who fought in Vietnam and who wish to use maps to preserve their history of the conflict, to note war graves and to seek closure in MIA/POW questions. Your Senator will likely ignore a single letter from you, but quite likely a series of letters arriving from Vietnam veterans and veterans’ organizations will nudge the Senator’s political instincts into action. Likewise, a law firm may be more likely to donate "pro bono" legal work if more than one person is involved.

If you are a government employee working within an agency that is deliberately restricting public access to public data (as, for example, NIMA does at this writing with VMAP?) make written notes of any such activities you observe. If you hear of any legal case filed, send your notes anonymously to the legal team filing the case. It will be a big help.

Encourage financial support from foundations, individuals, companies, and other organizations to promote public access to public data.

Tell your friends about manifold.net and encourage them to buy a copy. Manifold supports public access to public data (where else would you read a rant like this?) and provides a practical tool to get GIS data out of exotic Federal formats and into formats usable by many different GIS products. Manifold is also the only affordable way that ordinary people can work in a sophisticated way with sophisticated data.

The Freedom of Information Act (FOIA)
The Freedom of Information Act and its recent update, the Electronic Freedom of Information Act, guarantee access to virtually all GIS data created by the US government. There are only nine statutory exclusions to FOIA plus a pseudo-exclusion related to certain copyrighted map information provided to the Federal government. Use a good search engine to find sites devoted to FOIA and making FOIA requests. Numerous web sites will provide step-by-step instructions. These notes discuss issues especially relevant to GIS.

Many states have statutes equivalent to the FOIA for access to state information. Some, such as California's public records act, are considerably stronger than the FOIA because they award attorney's fees to the information requester if they have to go to court to enforce the act against an uncooperative agency.

Universal Access through FOIA

FOIA covers virtually everything created by the Federal government. If you see a printed map or a web image created by the Federal government, it's almost certain you have a right to the GIS data that was used to create that map or image. Ask politely to get the data. If you are ignored, send in a FOIA request letter. Send all letters by certified mail, return receipt requested so they know you know when they got the letter. The agency then has 10 or 20 days to respond.

If your FOIA request is denied, they have to tell you why, citing explicitly which exemption is being used. Don't accept any excuse that is not in the specific statutory exclusions. For example, NIMA stonewalled release of VMAP1 for years with excuses such as "our security office has not approved it" and so on. If it's not actually classified (a specific Federal designation that is the result of a specific process) it doesn't matter what their security office thinks of the matter. If it is not classified or not a copyrighted map provided by a third party under (rare) certain conditions you have a right to get it.

In recent years, some agencies have seeded public data with private, copyrighted material as a means of tainting all of the public data so that it cannot be forced into public hands via FOIA requests. We believe this is illegal and that the agency would have to provide, at a minimum, all data it originated, "unwinding" the poisoning of the data at its own expense. A related tactic would be to file a FOIA request for all of the documents the agency has that prove the copyrighted material is, in fact, copyrighted and did not enter the public domain as a result of a dealing with the Federal agency.

In many circumstances material provided to the Federal government enters the public domain automatically unless certain procedures are followed to keep it out of the public domain. This is to prevent contractors from selling data to the government for public use and then seeking to deny the public use of the data. If the supposedly "copyrighted" material used to taint the public data is also in the public domain then this FOIA exemption no longer applies.

Costs

Agencies can charge the cost of locating and duplicating information in response to a FOIA request, although the first two hours are free. You can ask them to process your request only up to the two free hours allotted by law. If you ask for electronic transmission of GIS data via FTP, the marginal cost of sending GIS data via FTP is zero. You should be able to get almost any GIS data set within the statutory two free hours. Agencies may attempt to deny you access by threatening to levy very high costs for what really costs nothing to FTP. Hold your ground and appeal all such constructive denials of your rights under FOIA. If you seek a large data set and do not have a large FTP site, contact the webmaster@manifold.net to inquire about access to our mammoth FTP sites for use as incoming sites to receive FTP delivery of data pursuant to a FOIA request.

Be Fair, Be Firm

It is essential to know FOIA and your rights under it. It also is critically important from a moral and tactical perspective not to abuse FOIA by filing requests for data that has already been published, or to use FOIA to harass your fellow citizens in government who are doing their best to make data available. Please be flexible and be reasonable whenever using FOIA. Most government agencies are highly professional in responding to FOIA requests. Understand the process and do careful research on the data you seek so you can write a focused, efficient FOIA request that does not require unnecessary work to process.

In many cases, making a few patient and responsible telephone calls or sending a few emails will eliminate the need to file a FOIA request. Many agencies and researchers are perfectly happy to provide a copy of a public data set in an informal manner. If someone does help you informally, do not abuse their goodwill by publishing their name on the Internet so they end up regretting their help to you. Do your best to help republish the information so that you too help disseminate the data.
Likewise, once a FOIA request is filed you should be firm in advancing the request. When asking for a politically sensitive data set you may be contacted by government representatives. They may try to convince you either not to pursue your FOIA request or to agree not to republish any data you get. Hold your ground. Be reasonable, but be firm. The requested material is either in the public domain or it is not. If it is not and the agency denies your request, they must cite the FOIA exemption used for denial. Get everything in writing and do not make verbal agreements authorizing delay, modification or abandonment of your request.

Most FOIA requests are handled in a highly professional (albeit slow) manner. If an agency has no political or internal "furf" issue with releasing data, you'll often get what you request very quickly. If the data requested is politically sensitive the situation is quite different. Our experience is that the art of using FOIA with unresponsive agencies is mainly the art of persevering in the face of various bureaucratic maneuvers intended to make you forget about your request.

It is important to persevere with FOIA even if you don't intend to (or cannot afford) the ultimate step of going to court to compel action on your FOIA request. Filing a FOIA request and then following through is a simple matter of sending a few letters. If enough people file FOIA requests for important data sets held hostage by recalcitrant agencies (as, for example, in the case of VMAP1 being withheld by NIMA), then pressure builds upon the agency to deal fairly. Within many people file FOIA requests for key data sets, sooner or later the agency faces a real showdown in front of a judge where the judge will see a case record littered with numerous examples of underhanded agency maneuvers. In such cases judges have been known to award millions of dollars to FOIA requestors to compensate them for their legal costs incurred.

The GNU License

The Free Software Foundation originated the GNU ("GNU is Not UNIX") project to create a freely distributable version of UNIX. One of the results is Linux. To support this effort the Foundation created a license under which software could be freely distributed and freely used.

As used by GNU, the usage of the term "free" above is not focused on a meaning of "free of cost". The key notion is freedom of usage. Many data are free of cost but suffer drastic restrictions on usage. For example, GIS companies often provide maps that are free of cost but which are subject to severe restrictions on utilization such as restriction to use only with the proprietary software packages of the originating GIS company. Such restrictions make it impossible for such maps to be used in open public policy discussions, because the restrictions require everyone participating in the discussion who wishes to see the full richness of the data in the maps to agree to the various proprietary licensing restrictions of a particular GIS company.

In other cases, non-profit organizations often publish maps that are provided free of cost but which may not be used for commercial purposes or by commercial organizations. We strongly believe that speech that is edited, even for a "good" purpose, is still not free speech. For someone to say you may use a map but not for commercial purposes as a practical matter is a very significant intrusion into your organizational life. It raises the question of when your behavior is "commercial" and when it is not.

As anyone knows who has done accounting for organizations that engage both in "commercial" and in "non-profit" activities, the distinction is often quite difficult to make and highly subjective in nature. Note also that blanket prohibitions on "commercial" usage would prevent the "chain reaction" mechanism of shareware publication that has enabled millions of CDs to be published at very low prices and near-zero cost to software authors. Commercial interests can often be harnessed to publish data and software at very low cost for the public good.

It has often been remarked that "public domain" data is already in the public domain and thus constitutes a freely distributable data set already. The problem with "public domain" data is that anyone may change such data slightly or convert it into a new format and then claim a copyright on the new form and use such a copyright claim to restrict further distribution. In fact, much of the GIS map data now sold by private companies under onerous restrictions originated in "public domain" data. Perversely, much data has emerged "in the public domain" only to be intercepted by a web of proprietary interests before it can reach users.

The GNU "copyleft" license resolves all the above problems by copyrighting the underlying programs or data and by licensing them under a specific license. The license (in informal summary, see the license itself for the precise terms and conditions) says you may freely use the data in whatever way you wish, so long as you pass on in any subsequent redistribution or usage the clearly stated right for any of your users to do the same. This goes for any modifications of the data or programs covered by copyleft. You can change the data, edit it, improve it, simplify it, sell it, or give it away. However, you must clearly inform all of your users that they are free to do the same as well so long as they too, in turn, agree to the full provisions of the GNU copyleft license.

In this way, any maps that are distributed under the GNU license become seeds for yet further redistribution. Any improvements to the maps likewise become available to anyone else. Because of the GNU copyleft license, no one can take your maps and use them as a means of restricting usage, conversation, duplication, conversion to any other format, or any other restriction. This does not prevent anyone from selling programs or other data that
may accompany GNU-licensed maps. It simply means one cannot restrict such maps in any way except by the "chain reaction" terms of the GNU license itself. It is this chain reaction effect that has been an important factor in the worldwide growth of software like Linux.

We don't suggest that the GNU license is the only way to license maps for distribution. We simply recommend it as one way of publishing GIS data in a way that will assure continued public access and free usage if that is the intent of the publisher. There are many other reasons for creating and publishing maps other than to provide public access to public data. In particular, private access to private data is an entirely different thing.

Please do not read this essay to infer in any way that manifold.net is against commercial map publication for profit. In our view, respect for private property rights is the flip side of the same coin as respect for public property rights. Just as public data should be protected against privatization, private data should be protected against forced transition to a de facto public domain status. Private vendors have every right to offer their intellectual property for sale (including maps) however they see fit. Private map creation and sale for profit are essential mechanisms for the creation of many important, value-added or original new maps.

Acknowledgement

Much of the material in this topic is used by permission and comes verbatim from the writings of the Free World Maps Foundation, which seeks to assure public access to public data in support of citizen democracy.
Zip Codes are Not Areas

ZIP codes are postal codes in the United States created by the US Postal Service. Perhaps the most common misconception in GIS is that Zip codes are polygonal regions or areas. People often think of mapping in the US as a hierarchy of ever-subdivided polygonal areas: states, counties, cities, zip codes. If they need higher resolution than a county, they next leap to zip codes because they think of zip codes as polygons. This is not true.

Zip codes are linear features associated with specific roads or with specific addresses such as apartment buildings or military bases that are best regarded as a point. In some cases, Zip codes have no physical location because they are assigned to a mobile or abstract “location” such as a military ship.

Even in the most common case of Zip codes assigned to streets, Zip codes do not clump together in groups that may be covered by rational polygons. We can consider an example using a map of part of Reno, Nevada, shown below. This map is fairly typical of the situation in mid-sized urban areas. It is extracted from the US Census Bureau’s TIGER/Line 1997 data set, which includes roads as segments of lines, with most line segments coded with Zip and Zip+4 codes for that particular segment. In this note, we will refer to both Zip codes and the Zip+4 extension together under the name “Zip code”.

To create polygons from road lines where lines have a common zip code there are several approaches. One possible approach is to select all line segments with the same Zip code and to then draw an area (polygon) that encloses them. This can be done by creating a buffer zone about each street line having a particular Zip code and then doing a Union of the buffer zone areas thus created. The blue, purple and green areas were created in this way and each represent a a different Zip code value.

The road lines shown in red selection color all have yet another Zip code in common. Immediately there are three pathologies visible in this map.

First, note that the blue area is not contiguous. Second, note that there are many regions of overlap between the blue and the purple areas and between the purple and green areas (we should have used varying layer opacity so that the regions of overlap were clearer). Third, note that at least one road segment highlighted in red (all having the same Zip code) occurs inside the purple zone where it is completely surrounded by all adjacent streets having a different Zip code.

The above situation is extremely common. In fact, we selected this particular map at random. Any urban map in the US will show similar, if not even more bizarre effects. Rural maps can have such a sparse network of roads
with such strange zip code assignments that some rural areas cannot even be approximated with zip code regions.

For the above reasons, any map that purports to show “Zip Code Areas” or “Zip Code Polygons” should not be taken as a precise map showing zip code locations. It is at best some sort of approximation and most likely is wildly inaccurate in certain regions. The approximations can be useful, but they should not be confused with the real thing.

The US Postal Service, of course, doesn't make it any easier to deal with such issues by making it easy to get Zip code information. Zip code information is not available for download via Internet from the US Postal Service. It is best obtained from (of all agencies!) the US Bureau of the Census.

**ZIP Code Tabulation Areas (ZCTAs)**

For statistical tabulation purposes the Census Bureau has long found it convenient to work with Zip code groupings of population. Zip codes have been so useful that the Bureau embarked on a project to create a standardized map of the US showing the approximate region of coverage of various Zip codes as areas. These areas are known as **ZIP Code Tabulation Areas (ZCTAs)**. ZCTAs may be downloaded from the Census Bureau’s [www.census.gov](http://www.census.gov) site. Drill down to the Cartographic Boundaries pages to get ZCTAs. Download them using .e00 format so they will import into Manifold using the correct NAD83 datum.

Before ZCTAs were published, every vendor of maps used in GIS had to resolve the various ambiguities posed by Zip code pathologies like those shown above. With ZCTAs the GIS industry can now use a standard approximation that is the same used as the Census Bureau for publishing demographic information. It is not clear if the Bureau will continue to create ZCTAs after the year 2000; however, they are so useful we believe they will become the industry standard for maps representing Zip codes as areas.
Just Say No to GIFs

If you run a web site please try to avoid using .gif format. Use .png for images that must be lossless and use .jpeg for imagery where lossy compression is OK. It's not just good technology it's also a matter of ethics.

Here's why:

The LZW (Lempel-Ziv-Welch) algorithm for compression in software has been patented not once but several times: It has been patented by both IBM (U.S. patent 4,814,746) and Unisys (U.S. patent 4,558,302). British Telecom has also been awarded a similar patent in the UK. IBM's patent was filed three weeks before the Unisys application. Both patents were granted in 1983. In a typically inept maneuver the U.S. patent office issued patents to both IBM and Unisys for the same algorithm, apparently not realizing that the patents covered the same "invention."

.gif was developed by CompuServe and published as an "open" format in the 1980's without realizing that the LZW compression used to create compressed .gif files could be subject to patent claims by Unisys or the other LZW patent holders. Based on the alleged "open" nature of .gif it became a widely used format. At some point, Unisys became aware that .gif files were created using LZW and decided to begin "enforcing" its LZW patent. Unisys has sought to extract money payments from companies who create software that writes .gif files, in particular in 1994 and 1995 launching a series of initiatives that successfully alienated numerous software developers. At one point, Unisys claimed to be able to require royalty payments from every web site that had a .gif image in it. In contrast, IBM has never sought to enforce its LZW patent against .gif developers and users.

In 1995 CompuServe launched the GIF 24 initiative, to develop a replacement for .gif not held hostage by software patents. Other developers launched the GEF initiative, which soon converged with GIF 24 to create .png. .png is a true "open" format not subject to patent claims by anyone. It is more efficient than .gif to boot and a much better choice for network graphics in the modern age.

Many developers and patent attorneys feel that it is only an accident caused by the ineptness of the U.S. patent office that Unisys was awarded a patent on LZW compression in the first place. Many developers feel so badly about Unisys' campaign that they have pledged to maintain only "gif free" web sites and avoid purchasing Unisys products or services. See http://burnallgifs.org for an example of some developer feedback on Unisys and .gif.

At manifold.net we now use .png format instead of .gif for all graphics publication on web sites. We have done so mainly because .png provides better compression and thus better performing web sites for lower bandwidth. Even so, it's also nice to know that with every .gif replaced with a .png we help strike one more blow against wrongheaded patent policies.

Remember: friends don't let friends drive drunk, and they don't let them use .gif either!
Beware of Counterfeit Software

By some estimates, over 40% of the software used in business settings in the United States is illegally copied or "pirated." Many businesses and users in the US will use copies of software for which they are not licensed. In some countries, well over 95% of the software in use is pirated. Software pirates include casual, amateur copiers of software as well as those who sell and those who buy professionally pirated software products.

In most Western countries, the number of users who make casual copies of software in violation of their license agreements greatly exceeds those who use the products of professional pirates. At manifold.net we feel an important part of keeping prices down is to provide a level playing field so that those customers who play by the rules do not end up subsidizing those who cheat. Using serial numbers and activation effectively eliminates casual cheating, the bulk of piracy in most Western countries. We feel that strong criminal sanctions by government authorities will make trafficking in professionally pirated products too risky for most users in industrialized countries.

In some countries virtually all of the software products that are sold are professionally pirated products that are ripped off on a massive, industrial level. It is always possible that professional pirates may circumvent the serial number and activation mechanisms in Manifold System. However, the technical effort to do so is very substantial and immediately marks any vendor or possessor of such a pirated form of Manifold System as a blatant lawbreaker.

Governments in countries where piracy is rampant have begun to realize that widespread piracy prevents the development of an indigenous software infrastructure within their countries. No one will create software for a market where software is universally ripped off. As a result, those governments have begun cracking down on software pirates.

All genuine Manifold System software from Release 5.00 onward requires a serial number and activation for permanent installation. If you have been supplied with Manifold System 5.00 or a more recent edition that does not require a serial number and activation, you may have been the victim of a counterfeiter. Contact sales@manifold.net to find out if the license offered to you is a valid license.

Resist the temptation to purchase or to install counterfeit software. When visiting countries in which counterfeit software is openly sold it is tempting to purchase a CD for a few dollars that contains thousands of dollars of software packages. However, when returning through Customs with pirated software you risk severe legal consequences if you are caught, including possible detention, conviction and the life-long stigma of a felony criminal record.

Customs officers know to examine hard disks and are very good at finding counterfeit software goods when people return from countries where such goods are sold. Remember, Customs officers look tens of thousands of people in the eye and do searches for hours every day of their work week for years on end so they have much more experience detecting a possible problem than the novice smuggler has at concealing it. You may think you have the iron nerves required to bluff your way past an experienced Customs officer, but when you face that officer across an examination table and realize that he or she can strip search you or otherwise detain you it is too late to realize the stakes are not worth the risk.

Criminal penalties are often much higher than the amateur smuggler realizes. For example, when smuggling a counterfeit CD into the US it is very easy for the dollar value of the ripped-off software on the CD to total many thousands of dollars, which escalates the offense into the range of a serious felony. Even if extended jail time is avoided upon conviction, in the US people with a felony conviction lose many rights for life, including the right to vote, the right to own firearms and even the right to work at many jobs or professions. That is true whether you are caught in Customs or caught when pirated software, unknown to you, calls down authorities within your own country.

If offered counterfeit software within your own country or via the Internet, consider that counterfeit editions of popular software packages may include viruses or Trojan Horse "back door" programs that later allow entry into your computer system. Such programs can be used to automatically harvest (via network connections) information from any computer system running the Trojan Horse. This is a classic way to take over machines to steal credit card information or identity or to use your machine to perpetrate credit card theft or to generate spam. Criminals can use Trojan Horse programs to use your machine to make purchases on their behalf using stolen credit cards. When the crime is discovered, it will be your computer and your Internet connection that will seem to have committed the crime.

Criminals use counterfeit software to distribute viruses and Trojan Horses for three reasons: First, virtually all software requires Administrator rights to install so the criminal knows you will be giving his installation script full Administrative permission to do whatever it wants in your machine. Second, embedding malicious code within counterfeit software is a great way to avoid scrutiny by anti-virus or malware packages. Finally, the criminal
knows that when you install counterfeit software you yourself will be committing a crime so you won't seek help from law enforcement authorities in case of trouble.

A final consideration is that some software companies are taking active measures against counterfeiters by placing special lures within their anti-piracy code that they know will be found and eliminated by counterfeiters. However, such lures can be craftily designed so that when they are removed the application begins emitting signals through Internet connections that advertise the use of a pirated copy to the software company and to law enforcement authorities. By using what you think is a safely "cracked" counterfeit copy, you could be inviting the police to raid your home or business.

Although it is true that raids are rare, especially in countries where piracy flourishes, even in the worst countries the authorities from time to time like to crush a few pirates, especially end users who are not making payoffs and won't be missed anyway, to show they take the piracy problem "seriously." In such cases only a fool would paint a target on themselves by unwarily using a cracked copy to invite a raid.

If you have never considered using counterfeit software the above comments obviously do not apply to you. However, you may find yourself some day counseling a friend or business colleague against the risks of using counterfeit software. The above information may help someone realize that the risks and possible costs of using counterfeit software are greater than they might appear at first glance.

Help Links

The topics in the Help Links chapter are here to capture and redirect users who may be searching the Help index using different terminology than that which is used within Manifold. These also provide indexing topics that provide a link to the main topic for that subject.

These topics provide cross-indexed links to the Manifold topics that cover the same subject matter.
**Arcs**

"Arcs" are called *lines* in Manifold.

**See:**

For Experienced GIS Users
Drawings
Terminology in GIS

**Note**

This topic is here to capture GIS users who are searching the Help index looking for familiar words. Use the links above to jump to the equivalent Manifold topics.
Polygons
"Polygons" are called areas in Manifold.

See:

For Experienced GIS Users
Drawings
Terminology in GIS

Note

This topic is here to capture GIS users who are searching the Help index looking for familiar words. Use the links above to jump to the equivalent Manifold topics.
Coverages

In vector-oriented legacy GIS products, the word "coverage" usually refers to a vector layer in a map that may be composed of vector objects such as points, lines and areas. Such vector layers are drawings in Manifold. Because Manifold maps can have drawings, images or labels components as layers in maps, we do not use the word "coverage" within Manifold. We simply speak of layers or we refer to the specific component type and speak of drawings, images, or labels layers.

Note that sometimes the word "coverage" is used in a slightly different context to mean "category of layers". For example, the US National Imagery and Mapping Administration (NIMA) uses this word within the VMap data set series to refer not just to one layer but to an ensemble of layers with a particular category. A boundary "coverage" within VMap data sets, for instance, may consist of several sets of line, point or area objects that in the normal use of the word would be considered separate "coverages."

See:

For Experienced GIS Users

Layers
Drawings
Images
Labels
Terminology in GIS

Note

This topic is here to capture GIS users who are searching the Help index looking for familiar words. Use the links above to jump to the equivalent Manifold topics.
**Grids**

The word **Grid** may occur in three contexts in Manifold:

- To import data sets from legacy GIS products, where surfaces are known as "grids."
- To create a mesh of horizontal and vertical lines, like a graticule.
- To denote a type of projection specific to some country.

In vector-oriented legacy GIS products, the word "Grid" usually refers to a regularly arranged data set that is used to show elevation or other data. Such a data set may be either a raster or vector data set. In Manifold, such data sets are referred to as **Surfaces**. See the Surfaces and Terrains topic for information. **.e00 Grid Files** is a choice in the File - Import - Surface dialog.

The word **Grid** in Manifold is used to refer to an orthogonal mesh of vertical and horizontal lines, like a graticule. See the View - Grid topic for information on creating grids.

Within the projections supported by Manifold are many "National Grid" projections. These are usually adaptations of standard projection types with parameters specific to a particular country.

**Importing ESRI ArcInfo exported raster grid files**

**.e00** is the preferred format for importing grid files from ESRI products. However, ArcInfo can export raster data using "gridscii" format either as integer or floating point data. There appear to be no standard extensions for such files in universal use within the ESRI community. We suggest saving (or renaming) such files to use either a **.grd** extension for integer data or an **.flt** extension for floating point data. Use the File - Import - Surface importer set to **GRD** files for integer data and **FLT** files for floating point data.

**See:**

For Experienced GIS Users

- Importing Surfaces
- Manifold Projections
- National Grids
- View - Grid

**Note**

This topic is here to capture GIS users who are searching the Help index looking for familiar words. Use the links above to jump to the equivalent Manifold topics.
**Thematic Mapping**

Thematic mapping is called Thematic Formatting in Manifold. To create thematic maps we use drawings that are linked to tables that have data fields for the different objects in the drawing. We then use thematic formatting to change the color or other display characteristics of the objects based on a data field.

To create a thematic map we need to know how to import a drawing, how to link a table to it if it does not have a table already linked to it when it is imported and how to create a map using that drawing. We then need to know how to launch and operate the thematic formatting dialog.

**See:**

- Drawings
- Formatting Drawings
- Thematic Formatting
- Tables

**Note**

This topic is here to capture GIS users who are searching the Help index looking for familiar words. Use the links above to jump to the equivalent Manifold topics.
**Georeferencing**

Georeferencing is called **georegistration** in Manifold. See the Georegistration topic.

**Note**

This topic is here to capture GIS users who are searching the Help index looking for familiar words. Use the link above to jump to the equivalent Manifold topics.
Digitization
Digitization is called **tracing** in Manifold. See the Tracing topic.

**Note**

This topic is here to capture GIS users who are searching the Help index looking for familiar words. Use the link above to jump to the equivalent Manifold topics.
Digitizing Tablets
Manifold does not use digitizing tablets. The preferred method of working with images is to use scanners to scan paper maps as images and to then use Manifold's tracing tools and image editing tools to work with those images. Because the computer allows us to zoom far into images we can work with the mouse within Manifold to much greater accuracy than is possible with a digitizing tablet. Scanners are much less expensive than digitizers, are much more accurate and the scanner - mouse - software ensemble is much more flexible.

See the note at the end of the tracing topic for a discussion of digitizing tablets.

See

Tracing
Editing Images
Georegistration

Note

This topic is here to capture GIS users who are searching the Help index looking for familiar words. Use the links above to jump to the equivalent Manifold topics.
Map Algebra
Manifold has a free-form formulas and calculation capability that works on surfaces. This capability is available if the optional Surface Tools extension is installed.

See

Surface Tools
Transforming Surfaces
Transform Dialog Functions and Operators

Note

This topic is here to capture GIS users who are searching the Help index looking for familiar words. Use the links above to jump to the equivalent Manifold topics.
Making Mosaics
We can create mosaics of images or surfaces by copying and paste or paste append.

Suppose we have a set of images we would like to combine into a single image. Duplicate one of the images and give that duplicate a name, such as *my mosaic image*, and open that image. Open each of the other images in turn, hit **CTRL-A** to select all of the pixels in the image, **CTRL-C** to Copy all of the selected pixels, click onto *my mosaic image* to make it the active window and then Paste Append to paste the pixels into the mosaic image. As you paste append each image in turn into the receiving image it will expand as necessary. The end result is a single image that has pixels pasted from all of the other images, that is a mosaic of the other images.

The general technique, applicable to just about any georeferenced images and surfaces is set forth in the Download and Mosaic TerraServer Images topic.

**Note**

This topic is here to capture GIS users who are searching the Help index looking for familiar words. Use the links above to jump to the equivalent Manifold topics.
Rasterize

Converting a vector drawing or a map using vector drawings into an image is called rasterization in many GIS systems. See Printing to Files or Images.

Note

This topic is here to capture GIS users who are searching the Help index looking for familiar words. Use the links above to jump to the equivalent Manifold topics.
Slope and Aspect from Elevation Data

Surfaces can automatically show slope and aspect. Import a surface, open it and use View - Display Options to choose slope or aspect.

Note

What's New
What's New
This topic provides a starting point for users of previous Manifold System releases to see highlights of what is new in this release.

Users new to Manifold may safely ignore these topics and simply proceed with learning the system beginning with the Welcome and Read Me First topics.

Manifold System Release 8 introduces next-generation performance infrastructure for Manifold System products with faster rendering, extended spatial DBMS support and introduction of massively parallel processing for supercomputer performance in surface transforms. This new infrastructure enables hundreds of improvements in Release 8 and will provide the foundation for thousands of improvements in future updates and releases.

Although there are few overt changes in the user interface, the impact of infrastructure improvements, such as providing dramatically faster rendering, completely changes the feel of the product in daily use in a way that appeals to both beginners and experts alike. No one who has experienced 8 will want to go back to 7x.

Release 8 also responds to the increasing maturity and sophistication of the Manifold user community. New features supporting spatial DBMS in a revolutionarily inexpensive and transparent way open the door to individual users to employ spatial DBMS in their daily work. Spatial DBMS now costs no more than a single Enterprise Edition license.

Some individual users might think that spatial DBMS is not for them, that it is something that only concerns enterprises. Nothing could be farther from the truth - spatial DBMS is for everyone who wants lightning fast performance with large images and surfaces as well as fast and reliable storage for drawings. Modern DBMS is easy to install (installing an Express edition of SQL Server 2005 Express takes but minutes) and performance gains are dramatic.

Those same spatial DBMS features have become essential to small organizations moving into GIS as a result of the new affordability of GIS Manifold makes possible. Even if an organization has only three or four people doing GIS they still can benefit from features, such as multi-user editing, that previously only very large organizations could afford. Large organizations will also benefit from fully orthogonal and flexible spatial DBMS, so they run legacy technologies such as SDE side-by-side with modern replacements such as Microsoft SQL Server 2008 spatial technology.

Release 8 was developed around several focus areas:

- The prime focus was on next generation Manifold rendering engines for substantially faster display speed. Performance has been improved through re-engineering of rendering pipelines coupled with hundreds of tweaks throughout the system. The most visible aspect of the new rendering technology is progressive rendering, which frees the console for continued work even as a large display is rendered in portions.
- A second focus area for Release 8 has been dramatically extended support for spatial DBMS, whether using native spatial DBMS products such as IBM DB2, Microsoft SQL Server 2008 spatial (codenamed "Katmai") and PostgreSQL or using Manifold spatial DBMS technology that now confers spatial DBMS capability upon virtually any DBMS to allow storage of drawings, images and surfaces. In addition, manifold.net has released the new Manifold Spatial Extender for SQL Server as a free download to provide high performance spatial index capability for SQL Server 2005 installations until SQL Server 2008 becomes available to the public.
- The third focus area for Release 8 was transparent support for ESRI "SDE" geodatabases and ESRI "Personal" geodatabases in full read/write/edit capability using Manifold to interact with such databases.
Appendices

- A fourth focus area was extension of Manifold’s ability to use multi-core and multi-processor hardware into the supercomputer performance world of NVIDIA CUDA. Manifold can now take advantage of NVIDIA CUDA equipped systems to execute many functions virtually instantaneously using as many as 512 stream processors via massively parallel algorithms.

- A fifth focus area was extension of scripting capabilities into user interface scripting, allowing programmers to utilize virtually any element of the Manifold user interface within scripts. This allows extremely rapid prototyping, development of scripting "macros", fast implementation of "one-off" tasks and even creation of automated demo programs that manipulate the user interface under programmatic control.

In addition to the above focus areas, Release 8 provides the usual Manifold implementation of a few hundred user community wishlist items. These range from support for IronPython as a .NET scripting language to routine updates such as support for the latest TIGER/Line format. Beta testers have especially praised some new innovations, such as the new Autohide / Popup Panes capability, added in response to user community requests.

**Transition Issues for 8**

Key operational differences between Release 8 and the predecessor Release 7x include:

- Release 8 can read prior .map files but earlier Manifold release such as 7x cannot read Release 8 .map files.
- Release uses a new .map file format that enables much faster opening of images and surfaces. When an earlier .map file containing surfaces or images is opened, the format will be automatically upgraded to Release 8 format. This process will require some time and patience, but it is a one-time process. Afterwards, the new format .map files containing surfaces or images will open dramatically faster than before.
- Release 8 allows changing the area of interest for drawings linked from a DBMS. Such facilities will not work for linked drawings created with prior Manifold builds. Delete the drawing and re-link it.
- Applications using the Manifold API will almost certainly need to be recompiled. Programmers should study the detailed release notes for a guide to changes in code that may be necessary.

**Highlights**

Highlights of Release 8 include:

- **Faster .map file loading** - The new .map file format and enhanced data structures allows much faster opening and loading of .map files, dramatically faster in the case of projects containing large images and surfaces. In some cases, what used to take tens of minutes to open now opens in a few seconds.
- **Faster image and surface rendering** - Images and surfaces are rendered much faster, typically one hundred times faster in the case of very large images and surfaces. What used to take tens of minutes now happens in seconds.
- **Faster drawing rendering** - Drawings also are rendered much faster, often two to ten times faster with large drawings.
- **Progressive rendering** - Manifold now renders components using progressive rendering, where the user interface becomes active and available even before the component finishes rendering. This provides much faster workflow, because if we are opening a component with the intent of zooming into some part of it we can draw the zoom box and begin zooming as soon as enough of the component has been rendered for us to get our bearings.
- **Faster selections** - Visual selection tools have been optimized to work faster, typically two to four times faster.
- **Extensive View Caching** - Views are now cached so that Manifold rarely needs to re-render a view once it has been displayed. Using the Back and Forward view navigation buttons, for example, is instantaneous.
- **NVIDIA CUDA support** - Manifold will automatically utilize NVIDIA CUDA hardware that may be installed in the system and supported with CUDA libraries. Currently supported in many surface transform dialog functions, CUDA-capable plug-in cards provide as many as 512 stream processors for supercomputer power on the desktop for as little as $150 or less. Some applications fitting CUDA capabilities that might have taken tens of seconds or even minutes can be accomplished in hundredths of seconds. Although limited in the current implementation, CUDA is the first step in what the months ahead will clearly emerge to be the future of almost all GIS computing. In terms of revolutionary steps forward, this could well be the Release 8 feature with by far the most impact upon the future of GIS.
- Autohides / Popup Panes - We can now expand the size of working windows by auto-hiding panes, such as the project pane. Move the mouse cursor over the pane's tab and it dynamically expands for use. Move the mouse away and the pane hides itself into the tab to allow a larger working view.

- Manifold Spatial DBMS capability storing drawings, images and surfaces within almost any DBMS - Manifold Enterprise Edition or higher now can confer spatial DBMS capability onto almost any DBMS, including those that do not have native "spatial" facilities. Manifold can automatically create spatial indices to store drawings using a variety of supported geometry types and can also store images and surfaces within high-performace spatial DBMS storage. Drawings of virtually limitless size can be edited using Area of Interest specification on desktop machines. Manifold can store images of virtually limitless capacity with very high performance access and rendering using almost any commercial or open source DBMS you choose, allowing opening of even multi-gigabyte images in seconds. Even if DBMS is not used to store drawings, the ability to store images with very high performance into DBMS is something all serious users of Manifold should learn to exploit.

- Enterprise Edition support for Spatial DBMS export - Previously, Database Administrator Edition was required for convenient export of drawing into a spatial DBMS. With Release 8 any Enterprise Edition or higher edition can easily export drawings, images or surfaces into spatial DBMS in a single step, automatically creating spatial indices, marking the spatial table to be treated as a drawing and otherwise managing the spatial DBMS infrastructure to allow subsequent use of drawings.

- All editions can utilize Manifold spatial DBMS capability - Enterprise Edition continues to be required to connect to native spatial DBMS (DB2 with IBM Spatial Extender, Oracle OCI, PostgreSQL/PostGIS, SQL Server 2008) using native spatial capabilities, but any Manifold edition from Personal Edition on up can connect and utilize generic spatial DBMS capability conferred by Manifold once Enterprise Edition has been used to upload drawings, images or surfaces into the spatial DBMS. That includes use of spatial DBMS within SQL Server 2005 using the Manifold Spatial Extender for SQL Server.

- Manifold Spatial Extender for SQL Server - The spatial extender provides high performance spatial indices within SQL Server 2005 or more recent version. Works with SQL Server 2005 Express SP2 or more recent edition as well. Use the spatial extender with SQL Server 2005 to get started today with spatial DBMS within the SQL Server world. Manifold works automatically and transparently with the spatial extender when it is installed on a SQL Server machine for better performance.

- Spatial DBMS support for Microsoft SQL Server 2008 Spatial - This new Microsoft product (code named "Katmai") has been announced but has not yet been published for the general public. If you are lucky enough to have a pre-release version, your copy of Manifold has built-in support for SQL Server 2008 Spatial.

- Spatial DBMS support for IBM DB2 with IBM Spatial Extender for DB2 - Manifold also adds DB2 to the roster of native spatial DBMS products supported by Manifold. The IBM Spatial Extender for DB2 is a free download for IBM DB2 Express-C editions as well as full DB2.

- Spatial DBMS support for PostgreSQL - Breaking with the prior tradition of supporting only commercial DBMS products, Manifold now provides full native spatial DBMS operation with PostgreSQL equipped with the PostGIS spatial extension.

- Spatial DBMS support for ESRI SDE geodatabases and ESRI Personal geodatabases - Manifold can connect to SDE (also known as "ArcGIS") data stores using any DBMS supported by ESRI or to so-called "Personal" geodatabases, most frequently encountered within Access .mdb files. Manifold can import drawings from such geodatabases or link to drawings for read/write/edit dynamic compatibility with such linked drawings to add/delete/edit objects in such drawings, even changing their projections.

- Faster data access through the Data Source dialog - Access to data sources such as OLE DB, ADO .NET and ODBC has been streamlined into a new Data Source dialog. The new dialog remembers data sources that have been configured and makes them available within dialogs such as the Database Console or Administrator console. This makes it much easier to connect to databases because once a data source has been configured we can quickly double-click on it in the Data Sources dialog to use it.

- Changeable Area of Interest - Drawings linked from any spatial DBMS using an area of interest subset can now have the area of interest changed even after they are linked.

- User Interface Scripting - A massive new capability that enables programmatic control of virtually all Manifold user interface elements and even many non-Manifold user interface elements as well. Instead of working exclusively through objects within the API, programmers can now control the Manifold user interface as if someone were automatically calling commands from menus, clicking control boxes, making choices, entering text and so forth. All Manifold dialogs (many hundreds of dialogs) have been adjusted to allow user interface scripting. Uniformly praised by beta testers as a revolutionary step forward in convenience, power and flexibility.

- Numerous scripting improvements and new objects - The scripting system has been enhanced with new options, such as forcing a script to run in a separate thread if desired. Many new objects provide access to new Manifold features.

- Expanded command line and logging options - A variety of new command line options support discovery of programmatic command names as well as a set of new logging options that enable automatic recording of timings such as rendering and execution times.
• **Choice of IMS rendering formats** - The Internet Map Server can now render using a variety of graphics formats, such as .jpg or .gif in addition to the default .png format, as well as allowing specification of rendering quality.

• **IronPython scripting support** - We can now use IronPython, the outstanding .NET implementation of Python supported by Microsoft, for scripting Manifold in addition to the other .NET and ActiveX languages supported.

• **Extensive additions to imports and exporters** - Numerous new capabilities have been added to importers and exporters, such as a NetCDF importer and numerous improvements in TIFF (16-bit LAB data and 32-bit/64-bit CMYK data), DXF/DWG, improvements in KML/KMZ exports (layer transparency, extended coordinate accuracy, etc.), yet more options for PRJ file recognition and improvements to other formats.

• **Coordinate system (projection) improvements** - Numerous improvements have been added, ranging from the ability to better support rotation factors in custom datums to numerous new datums for European countries. EPSG support has been integrated to allow use of Microsoft SQL Server 2008 spatial, and extensive work has been done on auto-matching of coordinate systems with spatial DBMS in PostgreSQL and DB2 spatial extender.

• **Faster geocoder handling of extension address errors** - Misspelled addresses geocoded against a geocoding extension database can now be processed twenty times faster.

• **Numerous other improvements and bug fixes** - Release notes for Release 8 have been changed to separately itemize changes in the main development path from bug fixes within new features or features continued from 7x. Current release notes cite a total of 415 new items and bug fixes. Some new items, such as much faster image rendering, are massive features which themselves incorporate hundreds of internal changes. User interface scripting alone required thousands of discrete changes within the code base.

Limitations

Although Manifold may be used on Microsoft Windows 98, there are several key limitations in this operating system. Most limitations will also apply in Windows Millennium (Windows Me). To avoid such limitations, use Windows Server 2003, Windows XP or, in a pinch, Windows 2000. Manifold System is no longer supported in Windows 95 or Windows NT.

The best environment for Manifold System is Windows Vista, Windows Server 2003 or Windows XP. Windows 2000 is a fine system but visibly aging, so it is wise to jump to Vista, XP or Server 2003. Users are warned that support for Windows 98 and Me will not likely continue very long and may be discontinued at any time.

If this documentation is still in use at a time when support for Windows 98 and Me has been discontinued by manifold.net, all references to Windows 98 or Windows Me should be disregarded.

Windows 98 Limitations:

Areas not resizable - Area styles are not resizable in Windows 98 or Millennium. Area styles are fixed at size 5 in those systems since all they support is an 8 x 8 pixel bitmap matrix. See Area Styles and Size.

Crashes in Windows 98 - Manifold uses standard Windows virtual memory management facilities when working with components too large to fit into available RAM. Windows 98 memory management facilities are unreliable for large projects and will crash when Windows Server 2003, Windows XP or Windows 2000 will not. In addition, printing through Windows 98 is less reliable because these systems do such a poor job of memory management that internal bugs in printer drivers are more likely to surface. These are not Manifold crashes but are operating system crashes. When working with large projects, use Windows Server 2003 or Windows XP.

Printing Problems in 98 and Me - Windows 98 and Me are full of bugs that often affect printing. We suggest using Windows Server 2003 or Windows XP to prevent bugs in Windows from interfering with print jobs. Windows 98 or Me are so buggy that tech support will only investigate reports of printing problems in Windows Server 2003, Windows XP or 2000.

Map Server Limitations

Manifold IMS (Internet Map Server) is published for use in Windows Server 2003, Windows XP (Professional and up) or Windows 2000 (Server or Professional running IIS). The map server has been observed to work using the personal Internet server in Windows 98 and Me; however, Windows 98 and Windows Me operating systems are not supported for use with the Manifold map server. Performance with 98 or Me will be seriously reduced as compared to Windows Server 2003, Windows XP or 2000.

General Limitations:

Maximum Size of Projects - There is no limit to the maximum size of Manifold projects, nor is there any limit to the number of components in a project.
**Maximum Component Size** - No single drawing, table, image or surface can exceed 16 EB (exabytes) in size. Since one exabyte is $2^{64}$ bytes, about a trillion gigabytes, as a practical matter there is no size limit for these components. One will run out of disk space before the size limit is approached.

Comments, queries and scripts are limited to approximately 1 GB. Labels are limited to 16 EB when initially created, but any changes made to a labels component after it is initially created cannot exceed approximately 1 GB.

Limits on comments, queries, scripts and labels component sizes are approximate because the precise limit depends upon details of the specific Windows system in use and the operation of that system. For example, in certain systems the 1 GB approximate limit on such components can expand to 2 GB or even 3 GB on machines run with a /3GB boot option. However, because such expanded uses depend on many complex interactions the stated limit size for comments, queries, scripts and changes in labels components is only 1 GB (a vast amount for such things).

Note that the 1 GB limit on "queries" is the size of the actual SQL query text, not on the results of a query. This is somewhat of an absurd "limit" since it is very rare that one writes an SQL query longer than a few hundred lines, let alone more than a megabyte in size.

**Maximum Process Size** - 32-bit Windows operating systems cannot allocate more than 2 GB of memory per process. This puts an upper limit on system functioning whereby algorithms that need more than 1 GB of memory (even temporarily) cannot usually operate. For example, using `Dissolve` to dissolve millions of polygons with very large data attributes for each record can exceed the process limit. Research continues at manifold.net to work around this limit of 32-bit Windows systems. As a solution until either 64-bit Windows systems become generally available or until Manifold research finds a way to exceed the limit imposed by 32-bit systems, try running large algorithms in parts. For example, try running a large `Dissolve` on portions of a drawing and then do a `Dissolve` on the results of these runs.

**Printer Limitations** - Manifold uses standard Windows facilities to print to printers. Manifold passes the print job to Windows, which then calls the printer driver. There is no contact between Manifold and the printer driver at all, so that any Manifold print job passed by Windows to the printer driver is guaranteed "legal" since it arrives from Windows using internal Windows system routines. Experience with previous editions of Manifold showed that numerous printer drivers do not fully support the requirements of a printer driver documented by Microsoft, so that some "legal" but complex jobs passed by Windows to the printer would crash the driver.

Manifold therefore uses a very simple set of Windows calls in an attempt to avoid triggering bugs in printer drivers provided by the printer manufacturer. If you experience difficulty printing, make sure to check the printer manufacturer's web site to see if there are more recent drivers available for your use, since the difficulty may arise from a bug in the printer driver that has since been fixed. Note that Manifold is sold for use with printers that fully support Windows requirements for printer drivers.

**Memory Requirements for Large Maps** - Manifold is designed for an era where RAM memory is cheap and personnel costs are high. `Undo` and may other user-friendly features require a lot of memory to implement. In order to make it possible to cancel out of certain operations, operating memory requirements may temporarily increase to three or four times the size of the map loaded. Normally, virtual memory will handle such requirements; however, for best performance we recommend installing lots of RAM.

**Free Disk Space Required** - Manifold requires up to four times as much free disk space as the size of an uncompressed project. This free disk space is required for temporary files that are created for project management, to allow `Undo` of some commands and to allow abandoning edits.

See the Performance Tips topic for more suggestions on improving system performance.

See the Memory Requirements topic for RAM and hard disk memory requirements.

**Software Requirements**

**OpenGL Required for Terrains** - Manifold requires a functioning OpenGL subsystem to display terrains. If there are no OpenGL capabilities in the system terrain windows will be blank when opened.

**.NET Framework 2.00 Required** - Microsoft's .NET Framework 2.00 must be installed to run this edition of Manifold System.
Process Debug Manager Required for Debugger - To run the Manifold Debugger you must therefore have the Microsoft Process Debug Manager (PDM) DLL installed on your system. See the Debugger topic for more information.

A Note on Operating Systems - The Manifold team recommends Microsoft Windows Server 2003 or Windows XP. We believe that Windows 98 and Me were outstanding products for their era. In general we would like to make sure our product works the same in Windows 98 and Me as they do with the latest generation of Microsoft Windows releases. However, since modern Windows versions provide more capability than do Windows 98 and Me we cannot in our product add capability that does not exist in Windows 98 or Me. Our support plan for Windows 98 and Me is limited to verifying that our code conforms to the Microsoft standards and that any errata are a result of limitations in Windows 98 or Windows Me.

As good as Windows 98 and Me may be, Windows Server 2003 and Windows XP are spectacularly better - even on "small" machines all of your software will run better and faster. This is not intended as a criticism of earlier Microsoft Windows products; rather, it is intended to acknowledge the major product improvements Microsoft has delivered over the years. Note that these comments especially apply when working with relatively large amounts of memory. We urge you to switch to Windows Server 2003 or Windows XP. It's worth it!

We no longer support Windows 95 or Windows NT since Microsoft itself no longer supports these versions with key systems features, such as .NET Framework 2.0, that are used by Manifold System.
Contacting manifold.net

You can reach the Manifold team by visiting our web site at www.manifold.net or by sending email to sales@manifold.net. Please consult the web site for telephone numbers and other contact information for sales and distribution channels in your area. The web site is the first place to look for all contact information or changes.

Technical support for Manifold comes through the same distribution channel through which you purchased your copy. If you purchased directly from manifold.net, see the Technical Support topic for information.

Please address all corporate correspondence for Manifold Net via email to sales@manifold.net.

No Response to Postal Mail

manifold.net does not respond to hard copy postal mail as the costs of using hard copy mail are very much higher than using email. Use email to contact manifold.net. Be green - go paperless!

Suggestions for New Features

Manifold users are strongly encouraged to send in suggestions for new features or alterations in existing features. Every new Manifold release and service pack includes numerous additions that have been prompted by user suggestions.

Ground Rules for Suggestions

Send email suggestions to sales@manifold.net. Due to the volume of suggestions received, suggestions for new features will not usually receive a reply; however, all letters conforming to the rules below are noted and their suggestions are tallied with others received and compared to current internal product plans. There are several rules that apply:

• Do not send any suggestion or comment that you do not wish to become a part of the public domain, that is, freely usable by anyone without any control by you or compensation to you. All suggestions or ideas received by manifold.net enter the public domain and are not confidential. Do not send any information or communication to manifold.net that you want to remain your intellectual property. If you send it to manifold.net you are giving permission for that idea or suggestion to be used any way that manifold.net desires, including free publication onto the web for anyone else to use and also including sale to a third party, without any compensation to you or intellectual property claim by you. If you work for someone else, do not send any ideas, information or suggestions that do not belong to you or that are not already in the public domain.

• Suggestions for new features are generally prioritized by how many people request them. For example, if more people request enhancements in image editing than request enhancements in CAD-style drawing editing, the image editing tools will more likely appear sooner. However, suggestions made by just a single person could (and frequently will) appear in the very next service pack if the product planning team at manifold.net believes they will serve a large user base or if in some cases they are very easy to do and fit into an available engineering slot that would otherwise go unused.

• Not all suggestions will receive replies, but at times you may be contacted by manifold.net personnel to discuss your suggestion. If so, any such communications are not a guarantee that your suggestion will be implemented. Do not base your purchase decision of additional Manifold licenses on an expectation that a suggestion will be implemented as a feature.

• Any new features for Manifold are prioritized based on company plans and trends perceived from user suggestions sent in by email. Whether or not a new feature is implemented in a particular service pack or release depends upon its priority, the amount of time necessary to implement it and the availability of engineering slots within the development organization. Sometimes features of relatively low priority will be implemented ahead of high priority features because the low priority feature is easy to do and an engineering slot opens up in which that feature can be implemented.

• The product planning process excludes form letters, bulk letters, letters that were obviously not composed as a personal letter to sales and any letters cc’d to third parties.

• For those suggestions that are contributed by only a few people the personal credibility and expertise of the suggester count for a lot. People who provide expert, complete and detailed suggestions win the credibility that makes it easier for product planners to commit more time to exploring the possible implementation of the suggestion, even if only one person has requested it.

Tips for Effective Suggestions
Some tips on how to make product suggestions that will influence the product as rapidly as possible:

- Don’t call a new feature you would like to see a "bugfix." For example, comments of the form "I've found a terrible bug in Manifold - it doesn't include a full-featured word processor like Microsoft Word" are a good way to lose credibility. If the product does not do something as it is documented, that's a "bug". If it does not include a feature or capability you would like to see, or if it is missing opportunities for additions here or there that greatly expand the usage of an existing feature, that's a new feature suggestion.

- Describe the new feature clearly and focus on specific features. The more detail you can provide about how it would work the better. General suggestions are appreciated but are not as likely to result in quick results. Example: "I'd like to see some more CAD editing tools" is too general to be very helpful. "I'd like to see move, scale, rotate, and flip commands like those that were in Manifold 4.50" is very specific.

- If enumerating a list of related capabilities, give some sense of your priorities. Example: "I'd like to see some more object construction commands. The most important in priority order are interactive Bezier curve drawing, the ability to draw a line perpendicular to another line or area boundary, and, if possible, a "centerline" line drawing tool that would constrain the drawing of a line to the mid-point of any two lines or area boundaries."

- The product planning process values independent votes for similar features much more greatly than a cluster of votes promoted by an advocate. If many people independently throughout the world come to a particular conclusion and find a new feature important enough to write, that tells us it is something that is really important enough for many people independently to decide to suggest. In contrast, if someone makes a posting on a newsgroup that says "I think feature X should always have default setting Y... write to manifold if you agree" and we get a few dozen letters saying "I agree" with a copy of the posting, that tells us the default setting was really not a big enough deal for more than one person to feel strongly about, because no one else noticed it or cared until the issue was raised in a new group.

- The product planning process values personal emails. Letters that are cc’d to third parties are excluded. Send emails to sales@manifold.net and not to the personal email accounts of any Manifold employees you may know. You may think you are lobbying the right person, but what actually happens is that employees will not vote for you by composing a letter on your behalf to sales@manifold.net and so your advocacy will not be influential.

- The product planning process does not allow time for planners to do your research for you. For example, at times writers will send a brief summary of what they are interested in and will append a comment such as "For details, see the discussion in..." appending a URL to a discussion thread in some Internet forum. Product planners will not run down that URL and attempt to parse a discussion thread to try to figure out what, exactly, it is you are advocating. If the issue is not important enough for you to provide a crisp, detailed and standalone suggestion of what you want, then your comment will carry little weight and will have much less impact then an effectively advocated suggestion.

- If you are new to the product, don't jump to the assumption that something cannot be done and so a new feature is required. Research the documentation and Knowledge Base carefully. Take a moment to try out your ideas with your peers, perhaps by posting to Manifold-L the GeoReference forum (see the Help - Manifold on the Web topic for fast access to the Manifold online community and other resources) to see if you've missed something already in Manifold. If some preliminary exploration shows the idea is not already accomplished, please send it in. If your idea is already in Manifold but in your opinion too hard to find, let us know about that as well.

Suggestions for New Formats

We frequently receive requests to add a new format to Manifold System for import or export. We are always willing to consider adding new formats to Manifold. There are four main determinants as to whether a new format will be added:

- Do we have full and complete technical documentation on the format? If we have publicly available documentation (such as a URL) that completely defines the format it becomes much easier to consider. Send such a URL or document to increase the chances your request will be implemented. Please do not send confidential information.

- Is the format a difficult one or an easy one to implement? Easy formats that are well documented will almost always be added rapidly.

- Have we had other requests for the format? If we have had very many customer requests it is more likely we will add a format even if it is difficult to implement. For an easy format that is well documented we have in the past added formats after only a single request.

- Are samples available of data in that format? The more complex the format, the more samples will be required to make sure the importer works correctly. If you send in a URL to a page that has plenty of samples the engineering team will know that any new importer can be tested. If there is no way to test the importer it is unlikely engineering resources will be committed to a complex new format.
Therefore, the best way to get a new format added to Manifold System is to send Manifold a URL or other document that precisely describes the format in full and complete technical detail and that provides links to sample data that may be freely downloaded.

Users sometimes write "Can you add XyzGIS format? Their home page is www.xyzgis.com." This is not helpful because unless a very large number of requests for that format are received manifold.net staff will not take the time to search the site for documents that might define the format. The betting at manifold.net is that if the requester hasn’t bothered to search the site then the desire for the format cannot be very great. If you would like to advocate a new format, you significantly increase your chances by doing the detective work to find a solid technical description of the format and by providing some samples.

Many of the formats in Manifold were added at the request of a single advocate who patiently located the required information and forwarded it to the Manifold team for implementation.

Requests for Broken Formats or Nonstandard Implementations

Manifold users will occasionally encounter files in formats that Manifold imports where the file does not accurately utilize the format. For example, there are many programs that can be used to write "shapefiles" which do not correctly write shapefile format, and there are images said to be in "GeoSPOT" format that are not written in accurate GeoSPOT format. Manifold.net will at times receive requests to alter the Manifold importers so they will read such pseudo-standard files.

There are two conflicting philosophies about staying true to a format definition. One philosophy says if something can be extracted from a file even though the format definition is not followed then do it. The other philosophy says that it is important to observe formats strictly and accurately as a protection against unknowingly importing damaged data. The first philosophy is often more convenient in the short term, but can lead to catastrophes in the long term. The second philosophy is more safe and professional, but can be less convenient in the short term.

Manifold tends to follow the second philosophy, of taking format definitions seriously. However, if there is a large body of data that systematically violates a format (for example, a large collection of data made available by a government), the manifold.net team is willing to bend the format definition a bit and allow such data. If you need such a relaxation of standards, the best way to argue your case is to provide a URL or other information that documents the existence of a large body of data in that "broken" format.

The above advice also applies to requests for nonstandard implementations of other standards. For example, a few GPS receivers say they use NMEA protocols when in fact they use a blend of standard NMEA with proprietary exceptions to NMEA. A request to support such "nonstandard standards" is a request to support something outside the standard and it will only be considered if there is significant usage that departs from NMEA in that way. For example, if a single, obscure GPS model departs from the NMEA standard there is little likelihood that the nonstandard implementation will be supported. On the other hand, if a major government organization buys a few million such GPS units then it is more likely that the nonstandard implementation will be supported.

Suggestions for New Projections

New projections are like new formats in that they are often easy to add if complete technical information is provided. The best way to get a new projection added to Manifold System is to send Manifold a URL or other document that precisely describes the projection in full and complete technical detail, including all formulae involved in defining the projection if the projection is not a simple parameterized variation on an existing projection. See the comments regarding suggestions for new formats as a guide.

Projections that are simple parameterized variations of existing projections are easily added to Manifold via customization. If a customized projection is indeed a standard projection in your part of the world it is an almost sure-fire candidate for addition to Manifold System as a "built-in" projection. If you would like such a customized projection to be added as a "built-in" within Manifold, send your customization XML as well as technical references (so the manifold.net team can confirm your work) as part of the suggestion. If you do not have a customization XML but you know that the projection is a variation on an existing one, please send a technical reference URL that sets forth the projection.

Frequently Asked Questions

Does sending a suggestion count as a support incident? Not unless it is embedded within a support request or a bug report to which a reply is requested. Example: "How do I thematically format a drawing using a text field in the sort order I desire?" Please add a feature to specify sort order." This will be treated as a request for support and will cost a support incident. Another example: "I need to draw Bezier curves and I think you should add this
Manifold® System Release 8.00 User Manual

capability to Manifold. Is it in there already and if not, how long will it take you to add it?" This is also a question of tech support and will use up an incident. It is a frequent occurrence that new users will ask a question of tech support about a "new" feature they want without realizing it is already in Manifold. Whether a feature is or is not in Manifold, if you ask any question of tech support you will use an incident. To avoid using an incident, make it clear you do not want a response of any kind. See the Technical Support topic for details.

**Why are cc'd letters ignored?** Cc'd letters are ignored for three reasons: 1) Cc'd letters that involve a third party will frequently involve a political dimension as people sometimes want to "show off" to their peers or try to convince others of their views. Just as in tech support, we feel communications are kept most clear if the temptations of playing to a crowd are removed. 2) At times, a good response to a suggestion may be a series of questions or other email conversation. We would like to conduct such conversations in private to allow manifold.net personnel to discuss usage with the person making the suggestion. We feel it is important to observe our privacy policy at all times, even if one of the participants is willing to waive it. 3) It takes time sometimes to parse a cc'd document that was not originally intended as a suggestion. If a direct communications pipeline to the people who create Manifold is not important enough for someone to craft a letter specific for that purpose, then we feel the content of that letter is not important enough to include in the planning process.

**What if my continued use of Manifold is dependent upon a new feature I have suggested?** You should never acquire licenses based on anything other than the capabilities of the released product. Manifold is always subject to revision and alteration as manifold.net judges best. Although the product's evolution is guided mostly by user demands, keep in mind that other users may have different priorities than you do so that the evolution of the product may not include suggestions you have made.

**How do I find out the status of a suggestion?** Once a suggestion is made there is no way to tell the status until it appears in a new release. Manifold.net is grateful for all suggestions but is unable to provide reports of whether or not specific suggestions have been adopted and if so, when they will appear in the product.

**How do I find out the release dates for new Manifold releases?** In general, these are not published. Users participating in Manifold-L, the discussion list for Manifold System users, or the GeoReference forum, the Manifold forum for the Manifold System User Group, will often hear rumors from factory personnel about general time frames in which new releases are to be expected. However, because manifold.net does not publish firm dates for new releases any such rumors should be treated as no more than broad predictions that are always subject to change. See the Help - Manifold on the Web topic for fast access to the Manifold online community and other resources.

**Why are not suggestions on Manifold-L or GeoReference monitored?** - The main reason is that all Manifold users can write directly to sales@manifold.net but only a minority of Manifold users participate in Manifold-L or on other online forums. By having one mechanism for intake, that of email sent to sales, we can assure all users equal status in making suggestions and guiding the evolution of Manifold. This policy also reserves for Manifold-L and GeoReference the freedom of having informal conversations and "thinking out loud" before sending in a suggestion. Quite a few suggestions for "new features" will turn out to be simply a lack of experience and not realizing those capabilities are already in the product. Testing out such ideas in Manifold-L or GeoReference is a good way for new users to benefit from the knowledge of their more experienced colleagues.

**I've seen extensive discussions of features in Manifold-L or GeoReference that surely resulted in lots of suggestions but appear not to have had any effect - why is that?** - First, recall that only direct communications to manifold.net count in the product planning process. Because surprisingly few users who participate in a discussion on an Internet forum ever bother to send a suggestion to manifold.net it is often the case that an extensive discussion yields few, if any, suggestions. Second, on those occasions when participants in a discussion do take the time to send a suggestion to manifold.net, quite often the suggestion is clearly unoriginal. Letters that are simple forwards of a posting with an "I agree" appended, are obviously prompted by an advocate, and so carry little weight, if any, in the planning process. Third, discussions in Internet forums are often very general in nature and provide little specific guidance as to new commands or features that are desired. Finally, only a small percentage of Manifold users participate in Internet forums, so it could be that a larger majority of other users has steered priorities elsewhere.

**Suppose I absolutely need a new feature - can I pay for it?** Yes, although the cost is usually very significant, in the several tens of thousands of dollars to the hundreds of thousands of dollars, depending on the level of custom engineering. Custom versions of Manifold System or scripts can be created with specific features that are required. However, given the propensity of "tire kickers" to waste resources on projects that have no hope of coming to fruition, a non-refundable fee of several thousand dollars is charged to review a proposal for custom engineering. This fee is charged because a significant amount of engineering effort is required to simply analyze a proposal for custom modifications and to determine the feasibility of such modifications. Contact sales@manifold.net with your requirements if you are ready and willing to pay the expenses involved.

If you have any suggestions to improve the above guidelines, please send them to sales@manifold.net.
About Manifold System

The manifold.net team first came together in 1993 to create an improved set of mathematics libraries for the massively parallel supercomputer (then the fastest in the world) that was a joint project between Intel and the US Department of Defense. Improved algorithms led to dramatic performance increases, in some cases resulting in two orders of magnitude improvement. The team later created a series of graph theory and computational geometry libraries as well as a series of "visual workbenches" used to teach the libraries.

The workbenches allowed visual selection of complex data, such as road networks, followed by the application of algorithms drawn from the programming libraries. The workbench products quickly evolved into a GIS-like visual network package that became Manifold System versions 1.0 and 2.0 in 1997. Clients who saw the package suggested the product was superior in many ways to old-fashioned GIS products and urged the company to enter the GIS market with products designed specifically for GIS users.

Manifold System first burst upon the GIS world in January of 1998 as Release 3.00. Within five months Release 4.00 was issued in June 1998, followed by Release 4.50 in March 1999. Release 4.50 incorporated several hundred suggestions from users of Release 4.00.

Release 5.00 was created between October 1999 and December 2001 with final release of Professional Edition in January 2002. 5.00 benefited from thousands of suggestions submitted by users of 4.50, as well as from numerous suggestions contributed by users of Manifold Database Commander and Manifold 3D View Studio. Suggestions came from all continents and numerous countries with especially heavy participation from the US, Western Europe, Russia, South Africa and Australia.

Work on Enterprise Edition paralleled work on Professional Edition with final release in July of 2002. Both Professional and Enterprise are based on a common code base so that a single executable can be launched either as Professional Edition or as Enterprise Edition.

Release 5.50 was already in progress during the Enterprise Edition campaign with all company engineering resources devoted to the 5.50 campaign beginning in July of 2002. 5.50 introduced unlimited sized projects, exabyte sized images and surfaces and increased the maximum size of other components to 4 gigabytes. In addition, hundreds of modules were re-coded for faster performance using larger component sizes. Hundreds of internal and external improvements were added for 5.50 as well, with 5.50 issued in January, 2003.

Service Pack 1 (SP1) for 5.50 introduced over 110 new features such as rotatable point styles and thematic formatting for labels in June, 2003, and Service Pack 2 (SP2) added hundreds more in October, 2003, including the next generation Manifold spatial SQL engine. In late 2003 the Business Tools, Geocoding Tools and Surface Tools extensions were introduced.

Issued in May, 2004, the 6.00 release included over 470 items in the initial release and then 320 items in 6.00 SP1 issued in October, 2004. Release 6.00 was the first Manifold release to require Microsoft’s .NET Framework.

Release 6.50, with over 620 items in the release notes, was issued in August of 2005 and benefited from many thousands of comments and suggestions by what has become a vast, worldwide Manifold user community. Beta testers in Asia, Australia, New Zealand, Africa, Europe, North America and South America participated in the largest beta trials ever for a new Manifold release. The result was clearly the best Manifold System release ever.

In November of 2005 the planned service pack for 6.50, called 6.50 SP1 was extended with plans to incorporate native support for Oracle spatial technologies. The collaboration with Oracle went so well that numerous features originally planned for future releases were pulled forward into 6.50 SP1. In early 2006 plans were extended yet again to cover yet more new features and to enable support for IBM DB2 as well as Oracle and SQL Server. After the number of features went over 500 items it was decided to issue this release as a major new numbered release, not a service pack, and so Release 7.00 went to press in May of 2006.

Release 7.00 introduced major new capabilities, including massive support for Enterprise class applications requiring simultaneous editing by potentially thousands of people of drawings that can be terabytes in size when stored on Oracle spatial servers. New Database Administrator and License Server products made it easy for large organizations to deploy hundreds or thousands of licenses, while a new Personal Edition product kept price low and features breathtakingly high for individual users.

Following soon after 7.00, with the release of 7x Manifold was been extended to run natively on x64 platforms. 64-bit editions of 7x allowed storing more data in RAM which, together with other enhancements to 7x, increased the capacity of Manifold operations and provide performance benefits. 7x also started an era of more frequent updates, made possible by improvements in internal processes used by Manifold engineering, that can be communicated in an automated fashion using a new Automated Updates option.
In 2007 Manifold 8 was released with numerous advancements. Release 8 extended native spatial DBMS support to IBM DB2 Spatial Extender, PostgreSQL and SQL Server 2008 spatial. Release 8 also introduced Manifold-managed spatial indices that allow spatial DBMS storage of drawings, images and surfaces in almost any DBMS, even those without native spatial capabilities. Release 8 also introduced the Manifold Spatial Extender for SQL Server, a server-side Manifold facility that enables SQL Server 2005 or later SQL Server editions to provide high performance spatial indices at no additional charge.

Release 8 greatly extended Manifold performance with much faster rendering of very large images, surfaces and progressive rendering for drawings. Massively parallel multiprocessor support was introduced with built in support for NVIDIA CUDA, enabling use of up to 512 stream processors for supercomputer performance, over a teraflop, in certain surface computations. Release 8 also introduced a new peak in Manifold engineering throughput, with simultaneous development on multiple code bases at once. Toward the end of Release 8 development, maintenance on the final update for Release 7x proceeded even as Release 8 was being brought to completion and teams began work on the next generation product as well.

Manifold System now runs in almost every country in the world and would not have been possible but for the international reach afforded by Internet and modern technology. In fact, this topic was originally written on a Dell laptop on a train running from Brussels to Amsterdam. It was teleported into the main documentation set via Internet. Internet has made it possible for friends from all over the world to send suggestions accompanied by detailed examples and wish lists of improvements desired in every new release.

User meetings throughout the world and interviews with numerous users representing North and South America, Europe, Africa, Asia and Pacific regions helped incorporate priorities from many elite users who combine many years' experience in GIS with a deep understanding of Manifold System. Manifold has been born a true citizen of the world, combining the best ideas from the finest GIS users in every continent. Manifold's corporate infrastructure and facilities have also always been deeply internationalized. To serve users with the best possible GIS at the lowest possible price, Manifold has not only solicited the intelligence and suggestions of all the world's GIS users, it has also invested into the best of all the world's most development-friendly regions to provide the most efficient possible locations and framework for modern software development.

For all of the tremendous benefits to world civilization that have arisen from Silicon Valley, benefits to the world have increased as the original microprocessor technology invented in Silicon Valley has expanded into major software and hardware development centers worldwide. Manifold has participated in that trend: every line of the millions of lines of code that have comprised Manifold products has been written in Europe and Asia, with corporate facilities and infrastructure located in the Caribbean, Europe and Asia. Manifold's Hong Kong corporate infrastructure and facilities together with upcoming language localization in new products continue the commitment to create a true, world GIS with support for the world's largest population centers throughout the world.

Release 5.00 was begun on Intel Pentium III machines with development switching to Pentium IV and Athlon towards the end of development. The native development environment at manifold.net began with Windows NT 4.0 and switched to Windows 2000 early in the R5 campaign with final development switching to Windows XP in the last year of 5.00 work. Enterprise Edition and 5.50 were coded entirely in XP with adjustments and backports as necessary to support earlier Windows editions. Current hardware used for development includes multi-core AMD and Intel processors using the most recent published and beta editions of Microsoft Windows. Current development runs at least two major releases simultaneously with work on future releases proceeding even as existing releases are maintained.

Manifold System is written entirely in Microsoft Visual C++ within the Microsoft Visual Studio development environment. In January of 2002 Manifold development moved to Microsoft's Visual Studio .NET development environment to take advantage of the improved .NET compiler. In 2003 all new code was migrated to .NET with steady conversion of existing code to .NET as well. Release 6.00 and 6.50 were coded entirely in Visual Studio.NET using Windows XP and Server 2003 on a mix of Intel and AMD based machines, including 64-bit AMD machines. Release 7x continued the move to modern Microsoft standards, such as use of .NET, multi-core processors and introduced 64-bit computing. Release 8 moved to deeply multi-processor development environments using multi-core main processors and hundreds of accessory stream processors.

Manifold System is completely new software. It is not simply a revision of older systems or a pasting-together of controls from other vendors but represents completely new code. The multi-version executable that now comprises Personal, Professional, Enterprise, Universal, Database Administrator, Ultimate and License Server Editions includes well over 2 million lines of source code. Each new major build of Manifold typically involves writing, editing or reviewing over 750,000 lines of code, as major portions of existing code are re-written from the ground up or refreshed to make the latest advancements possible without hindrance from legacy code.

Except for standard Microsoft development facilities and an ECW format importer/exporter, there is no third party code in Manifold. It is all entirely our work. The ECW importer/exporter is a small bit of code provided by the
ERMapper organization and is included within Manifold to emphasize our support for ERMapper. In addition, some color palettes and combinations have been designed by Cynthia Brewer of the ColorBrewer project.

Hundreds of people have contributed to the programming, graph theory, general mathematics and computational geometry within Manifold System. Even given the immense content of prior releases, yet again Release 8 has been the largest team project ever assembled at manifold.net. Once again, we can say that 8 is easily the most sophisticated software product any of us has ever created. As is typical for every major Manifold release, during the last months of final assembly of each edition our lives have revolved around the product. It has been stressful for friends and family but in the end, the long march is always a tremendous kick as we are privileged to watch each release come to life.

The manifold.net team would like to thank our many friends around the world for buying our products and for being so generous with their suggestions. If you purchased prior releases it is your investment that made the current release possible. By purchasing the current release you are financing the extensive work required to make the next releases possible. We are grateful you have helped bring this new phase of GIS into existence by funding our work. We are also grateful to the many users of beta test versions who patiently downloaded dozens of test builds and contributed suggestions and bug reports to help evolve the product.

We give greatest thanks to our friends and families who have put up with our absences and total focus on Manifold. Things like Manifold System do not happen without intense dedication. We are grateful our friends and families support us in this magnificent obsession. We hope you enjoy the result. It is our honor to work on your behalf.
About manifold.net

Manifold® System editions and extensions to Manifold® System are distributed by manifold.net. Product configurations and pricing are subject to change without notice and may be different than the following descriptions incorporated into Help at the time of writing. See the web site at www.manifold.net for the latest information on new products.

Manifold® System Products

Manifold System appears in several main product and option configurations:

Manifold® System License Server - Manages operation of multiple instances of Manifold (all of the same edition) in large enterprise environments via floating licenses. This is not a runtime or interactive product for doing GIS: it is a version of Manifold that works exclusively as a license server.

Manifold® System Personal Edition - The super-cool GIS as documented by this Help file including all Professional Edition features except the Internet Map Server (IMS) and the File - Export - Web Page command used to create IMS sites.

Manifold® System Database Administrator Edition - Enterprise Edition also equipped with the Administrator Console to provide administrative and managerial capabilities essential when using Manifold together with enterprise-class database servers to provide centralized geospatial storage and concurrent, multi-user editing. The Batch Export tool for Oracle Spatial databases makes loading large databases with drawings, images and surfaces a fast and simple process. Every significant installation using databases to provide centralized storage and multi-user editing should have at least one license of Database Administrator Edition that is used to set up the database for greater convenience and capability when used with other Manifold editions by other users.

Manifold® Spatial Extender for SQL Server - A free product that installs into Microsoft SQL Server installations to provide high performance spatial indices for spatial DBMS capability. For SQL Server 2005 (including SQL Server 2005 Express SP2) and newer SQL Server versions. Works automatically with Manifold® System to provide high performance, enterprise class spatial DBMS facilities.

Manifold® Business Tools - An optional extension to Manifold System that provides additional commands for working with drawings. The Business Tools extension adds functionality in several areas:

- Districts (Advanced) - Redistricting using a condensed, expert level dialog.
- Districts (Visual) - Redistricting via an easy-to-use visual, interactive dialog.
- Drive-Time Zones - Computation of drive-time zones via an easy-to-use, interactive dialog.
- Optimal Route - Finding an optimal route to designated locations using a condensed, expert level dialog.
- Optimal Route (Visual) - Finding an optimal route to designated locations via an easy-to-use, interactive dialog.
- Send Email - Automatically send email to map objects. Used to send spatially-targeted email.
- Topology Factory - An interactive dialog to view and repair common topological errors in drawings.
- Expanded programmatic access to routing and other functions.

If you do not have the optional Business Tools package enabled you will not have the above capabilities enabled within Manifold System.
**Manifold® Geocoding Tools** - An optional extension to Manifold System that provides street address geocoding capability as well as access to the Manifold Geocoding Database data provided on the Manifold downloads site for both US street address geocoding as well as the easy creation of drawings showing US streets. The **Geocoding Tools** package adds functionality in several areas:

- Street address geocoding within the United States using the Manifold Geocoding Database provided on the Manifold downloads site.
- Street address geocoding within North America or Europe using the appropriate edition of Microsoft's MapPoint product as a data source.
- Street address geocoding anywhere in the world using user-provided geocoding data extensions in either range or points of interest formats.
- Street address geocoding using web-based Manifold geocoding servers to provide geocoding services.
- Easy import of drawings showing US streets from the Manifold Geocoding Database provided on the Manifold downloads site as set forth in the Import Drawing - Geocoding Database topic.
- Geocoding Extensions may be used within SQL to allow use of street address geocoding functions within SQL queries.
- Programming objects such as the Geocoder object may be used from scripts or other programs or from within IMS applications.
- Street addresses and ZIP codes may be used in the Edit - Go To dialog.

If you do not have the optional **Geocoding Tools** package enabled you will not have the above capabilities enabled within Manifold System. Note that the **Geocoding Tools** package requires access to a geocoding data source appropriate to the geographic region of interest.

**Manifold® Surface Tools** - An optional extension to Manifold System that provides additional commands for working with surfaces. The **Surface Tools** extension adds functionality in several areas:

- A new Surface - Transform command dialog allows arbitrary transformation of surfaces, including computations that involve multiple surfaces such as subtracting one surface from another. A very rich collection of operators allows many different types of tasks to be accomplished.
- A Transfer Heights command enables rapid transfer of surface values from surfaces to points.
- The Visible Area command shows areas that are visible from given points. The height of viewing points may be automatically adjusted from a height field.
- New options in surface generation allow creating surfaces from drawings and tables using triangulation and Median-Polish Kriging.
- Expanded model choices for Kriging interpolation include Linear, Power, Rational and automatic model choices.
- New transform toolbar operators for interpolation of missing pixels, *Interpolate, Interpolate (Parameter)* and *Interpolate Row*.
- The ability to work with new Profiles and Elevations components that show cross-sectional cuts through a given path over a surface.
- Sophisticated watershed capabilities and other hydrology functions.
- Expanded programmatic access to surface operations.

If you do not have the optional **Surface Tools** package enabled you will not have the above capabilities enabled within Manifold System.

All Manifold System editions, the **Business Tools, Geocoding Tools** and **Surface Tools** packages are included within one installation package. Which product configuration launches when you start Manifold depends on the type of serial number that was provided when you installed Manifold and first launched the product. If you provide a Professional Edition serial number then the product will launch in Professional Edition mode. If you provide an Enterprise Edition serial number then the product will launch in Enterprise Edition mode.

This makes it easy to upgrade your installation. If you are a Professional Licensee and would like to upgrade to Enterprise Edition, visit the Manifold Online Store to order an upgrade product. You will receive a new serial number that you can use to upgrade your installation without the need to download a new installation.

**Runtime Licenses**
Manifold® System may be licensed in runtime mode by acquiring a runtime license of either Professional or Universal editions. Runtime licenses are not available for Personal, Enterprise, or Database Administrator editions.

A runtime license allows Manifold System to be used as an Internet Map Server (IMS) or via the applications program interface (API), but not using the interactive graphical user interface (GUI). Runtime licenses are intended to provide reduced-cost licenses for IMS applications or for third party programming where Manifold is embedded within a third party application.

**Manifold® System Professional Runtime** - Provides all IMS and API capabilities of Professional Edition without any interactive GUI capabilities.

**Manifold® System Universal Runtime** - Provides all IMS and API capabilities of Universal Edition without any interactive GUI capabilities.

Visit the [www.manifold.net](http://www.manifold.net) website for the latest news on Manifold products for data visualization, data discovery, business intelligence, mapping and more. Manifold tools work with Microsoft operating systems and other Microsoft products to deliver a seamless enhancement of your ability to see, manipulate, and analyze data using a visual, point-and-click interface.
This topic contains miscellaneous legal notices, some of which may be applicable only if you are a source code licensee of Manifold System.

As noted in the About Manifold System topic, this product is entirely our work with the exception of a few items, for which credit is due:

**ColorBrewer**

Your Manifold distribution may contain color palettes (choices of colors) that originate in the ColorBrewer project. If so, the following license terms and provisions apply:

Apache-Style Software License for ColorBrewer Color Schemes
Version 1.1
